EXECUTIVE SUMMARY

The North Dakota Department of Health operated ten ambient and two special purpose air quality monitoring sites, industry operated eight source-specific air quality monitoring sites and the Three Affiliated Tribes on the Fort Berthold Indian Reservation operated two ambient sites. The data from these sites indicated that the quality of the ambient air in North Dakota was generally good during 2001.

There were no sulfur dioxide, nitrogen dioxide, ozone or particulate matter exceedances of either the state or federal ambient air quality standards measured during the year. Through legislative action effective August 1, 1997, coal conversion facilities and oil refineries were exempted from the state sulfur dioxide standards. Therefore, any values listed as an exceedance in the data summaries are subject to further manual review to determine the most likely source(s) causing the listed exceedance.
INTRODUCTION

The North Dakota Department of Health, Environmental Health Section, Division of Air Quality, henceforth known as the department, has the primary responsibility for protecting the health and welfare of North Dakotans from the harmful effects of air pollution. The department ensures that the ambient air quality in North Dakota is better than the levels required by the state and federal Ambient Air Quality Standards\textsuperscript{1,2} and the "Prevention of Significant Deterioration of Air Quality Rules."\textsuperscript{3} To address this responsibility, the department operates a network of ambient air quality monitors.

In addition to the state-operated ambient air quality monitoring sites, three industrial sources of air pollutants operated air quality monitoring sites within their immediate spheres of influence. These site locations are selected based on computer dispersion modeling and prevailing wind directions.

This report provides an overview of air quality monitoring activities conducted by the department and industry during the 12-month period beginning Jan. 1, 2001, and ending Dec. 31, 2001. The report includes data summaries for the monitored pollutants and significant changes that occurred to the monitoring program. Also included are wind and pollution star charts and trend graphs. The pollution star charts (Appendix 3) indicate the percentage of time a pollutant is detected when the wind is from each direction. The trend graphs (Appendix 4) show the maximum concentration for each pollutant standard and the percentage of time a concentration was above the minimum detectable limit for the specific analysis method.

The Three Affiliated Tribes on the Fort Berthold Indian Reservation operate a tribal network that consists of two sites: White Shield and Drags Wolf. The data summaries are included only for informational purposes, since tribal data is not subject to state ambient air quality standards.
NETWORK DESCRIPTION

Department Sites

During 2001, the department operated twelve air quality monitoring sites. Ten were ambient monitoring sites, and two were special purpose monitoring (SPM) sites near the AMOCO Refinery and MDU Heskett Power Plant at Mandan. Table 1 lists the department monitoring sites which were active during the year.

In general, department ambient air quality monitoring (AAQM) sites obtain air quality data to meet five objectives: (1) determine representative concentrations in areas of high population density (urban or population oriented monitoring), (2) determine general background concentration levels, (3) measure highest concentrations expected to occur in an area covered by an individual site, (4) determine representative impacts on ambient air quality levels near significant sources, and, (5) determine the effects of long-range pollution transport.

The department’s ambient air quality monitoring network normally does not include source-specific monitoring; i.e., monitoring a single, specific source. However, the two Mandan SPM sites were established to collect source-specific 5-minute peak and hourly sulfur dioxide averages due to impacts from the MDU Heskett Power Plant and AMOCO Refinery.

The department is working with Environment Canada, the Environmental Protection Agency (EPA), Saskatchewan Environment and Resource Management (SERM) and SASKPower to operate a North Dakota-Saskatchewan Transboundary ambient air quality monitoring network with three sites (Rafferty Dam, Estevan, Boundary Dam Power Station) in Saskatchewan and the two sites (Short Creek and Lignite) in North Dakota. The ND-SK Transboundary network became fully operational Dec. 5, 2000, when the Estevan PM$_{2.5}$ sampler collected its first sample. Data collected at these five sites are addressed in that network’s own annual reports.

The department, in issuing Permits to Construct and Permits to Operate for major sources, may require those sources to operate ambient air quality monitoring programs to assess impacts on local air quality.

Industry Sites

Industry operated eight source-specific air quality monitoring sites during the year. Table 1 also lists the industry networks and monitoring sites active during the year.
In general, industry air quality monitoring sites obtain data at locations expected to show high concentrations of pollution from a specific source. These source-specific sites are selected using computer dispersion modeling programs and annual wind patterns. The distance a monitoring site is located from a source is determined by the primary pollutant monitored.

Figure 1 displays both department and industry monitoring sites. If an industry has more than one site, only the general location within the county is indicated. This principle also applies to the Mandan location, which represents the two sites at Mandan.

Figure 1. North Dakota Air Quality Monitoring Network
NETWORK CHANGES

Department Changes

Changes to the state monitoring network consisted of adding, terminating and moving the following samplers to new locations. Speciation samplers were added to Bismarck Residential and Fargo NW along with particulate matter (<10 microns) (PM$_{10}$) samplers. The Theodore Roosevelt National Park - North Unit (TRNP - NU) site was re-activated in August 2001 with SO$_2$, NO$_2$, O$_3$, and MET. The Grand Forks and Sharon PM$_{2.5}$ samplers were terminated effective Dec. 31, 2001 with both of these samplers moved to TRNP - NU.

The Fargo NW speciation sampler was installed at EPA’s request and is a part of the EPA National Trends Network. As a part of preparing for the regional haze/long-range transport rule, the sulfate and nitrate concentrations were modeled using the latest dispersion modeling techniques. The result of the modeling indicated the Bismarck Residential site was located midway between the maximum sulfate (SO$_4^{2-}$) and nitrate (NO$_3^-$) areas. Therefore, the Bismarck Residential site was scheduled to receive a speciation sampler. To address the need for long-range transport/regional haze monitoring within the state network, TRNP - NU was re-activated and is scheduled to receive a speciation sampler effective Jan. 1, 2002.

Along with each speciation sampler, a Federal Reference Method PM$_{2.5}$ and Federal Equivalent Method PM$_{10}$ sampler will be operated. The rational for this monitoring arrangement is to collect the same data set as collected by the IMPROVE (Interagency Monitoring of PROtected Visual Environments) samplers installed at Theodore Roosevelt National Park - South Unit (TRNP - SU) and Lostwood National Wildlife Refuge (NWR).

Industry Changes

No changes were made to the industry networks.
MONITORING RESULTS

Introduction

Ambient and source-specific air quality data collected during the year at monitoring sites operated by the department and industry are summarized in tables for the following pollutants: sulfur dioxide (SO$_2$), nitrogen dioxide (NO$_2$), ozone (O$_3$), ammonia (NH$_3$), federal reference method inhalable fine particulates (PM$_{2.5}$), and inhalable coarse particulates (PM$_{10}$). Each section contains a description of the physical characteristics and health effects, a comparison to the state standards, and a data summary.

The data summaries for gaseous pollutants include maximum concentrations, month/day/hour of each maximum, arithmetic means and the percentage of readings greater than the minimum detectable value (MDV) for the analytical method used for each parameter. Where applicable, the number of times a state standard was exceeded is indicated. The concentrations for gaseous pollutants are reported in parts per billion (ppb).

The PM$_{2.5}$ and PM$_{10}$ data summaries contain the three highest 24-hour average concentrations; month/day of each maxima; annual arithmetic mean; the number of times the 24-hour standard was exceeded, if applicable; and an asterisk (*) if the annual standard is exceeded, if applicable. The concentrations are reported in micrograms per cubic meter (µg/m$^3$).

Continuous PM$_{2.5}$ data summaries contain the two highest 1-hour averages and the four highest 24-hour averages; the annual average; the number of times the 24-hour standard was exceeded; if applicable, and an asterisk (*) if the annual standard is exceeded, if applicable. The concentrations are reported in micrograms per cubic meter (µg/m$^3$).

For statistical purposes, pollutant concentrations less than the minimum detectable value (MDV) for the analytical method used are assigned a value equal to one-half the MDV. The MDV for SO$_2$ and NO$_2$ is 2 ppb; O$_3$ is 4 ppb; PM$_{2.5}$ is 2.0 µg/m$^3$; and PM$_{10}$ is 4 µg/m$^3$. The MDV for the continuous PM2.5 is -2.0 µg/m$^3$. Annual means are calculated for SO$_2$, NO$_2$, PM$_{2.5}$, and PM$_{10}$. However, only those means with more than 75 percent of data greater than the MDV are unbiased calculations.

As part of the statistical evaluation, the data recovery (NUM OBS) is evaluated to determine if the data recovery complies with the state’s required 80 percent data recovery rate. A continuous analyzer operating fewer than 7,028 hours per year may achieve at least an 80 percent data recovery for the period operated; However, it does not meet the 80 percent data recovery for the full year. Each analyzer at a site not meeting the 80 percent data recovery for the year is flagged in the “NUM OBS” column by
placing “***” underneath the number of observations. Particulate matter samplers must collect at least 48 samples per year for 1-in-6 day sampling and 96 samples per year for 1-in-3 day sampling to meet the 80 percent data recovery rate.
Sulfur Dioxide

Physical Characteristics and Sources
Sulfur dioxide is a colorless gas with a pungent odor detectable by the human nose at concentrations of 500 to 800 ppb. It is highly soluble in water where it forms sulfurous acid ($H_2SO_3$). In the atmosphere, sulfurous acid is easily converted to sulfuric acid ($H_2SO_4$), the major acidic component of “acid rain,” which then may convert to a sulfate. On a worldwide basis, sulfur dioxide is considered to be a major pollutant. It is emitted mainly from stationary sources that burn coal and oil – such as utility boilers. Other sources of sulfur dioxide include refineries, natural gas processing plants, oil well heaters and flares.

Health Effects
Sulfur dioxide can be converted in the atmosphere to sulfuric acid aerosols and particulate sulfate compounds which are corrosive and potentially carcinogenic (cancer-causing). The major health effects of sulfur dioxide appear when it is associated with high levels of other pollutants, such as particulate. Sulfur dioxide also may play an important role in the aggravation of chronic illnesses, such as asthma. The incidence and intensity of asthma attacks have increased when asthmatics are exposed to higher levels of sulfur dioxide and particulate matter sulfates, which are products of atmospheric sulfur dioxide reactions.

Standards Comparison
Sulfur dioxide was monitored at 17 sites. Eight sites were run by the department, eight by industry, and one by the Three Affiliated Tribes on the Fort Berthold Indian Reservation. As a result of legislative action effective Aug. 1, 1997, coal conversion facilities and oil refineries were exempted from the state sulfur dioxide standards leaving these two classes of sources subject only to the federal standards. Therefore, the Dakota Gasification Company (DGC) network, Mandan NW - SPM, and Mandan - SPM are compared only to the federal standards.

The 1-hour state standard (273 ppb) was not exceeded during the year by an applicable source. The maximum 1-hour concentration was 164 ppb at DGC #12.

The 3-hour federal secondary standard (500 ppb) was not exceeded during the year. The maximum 3-hour average concentration was 116 ppb at Mandan - SPM.

The 24-hour state standard (99 ppb) was not exceeded twice during the year. The maximum 24-hour average concentration was 38 ppb at Mandan - SPM.
Among those sites that collected at least 80 percent of the possible data during the year, the maximum annual arithmetic mean was 5.5 ppb at Mandan - SPM.

The sulfur dioxide data are summarized in Table 2.

The maximum 24-hour concentration is 38 ppb at Mandan - SPM on 01/15

* The air quality standards are:
  1. **STATE Standards** -
     1) 273 ppb maximum 1-hour average concentration.
     2) 99 ppb maximum 24-hour average concentration.
     3) 23 ppb maximum annual arithmetic mean concentration.
  2. **FEDERAL Standards** -
     1) 500 ppb maximum 3-hour concentration not to be exceeded more than once per year.
     2) 140 ppb maximum 24-hour concentration not to be exceeded more than once per year.
     3) 30 ppb annual arithmetic mean.

*** Less than 80% of the possible samples (data) were collected.
Sulfur Dioxide 5-Minute Average

Sulfur dioxide 5-minute averages were collected at state-operated sites and the Bear Paw Energy network. The maximum 5-minute average was 229 ppb at Mandan - SPM.

The sulfur dioxide 5-minute data is presented in Table 3.

Nitrogen Dioxide

Physical Characteristics and Sources
In its pure state, nitrogen dioxide is a reddish-orangeish-brown gas with a characteristic pungent odor. It is corrosive and a strong oxidizing agent. As a pollutant in ambient air, however, it is virtually colorless and odorless, although it may be an irritant to the eyes and throat. Oxides of nitrogen, nitric oxide and nitrogen dioxide, are formed when the nitrogen and oxygen in the air are combined in high-temperature combustion. Nitric oxide released into ambient air combines with oxygen to form nitrogen dioxide. Major nitrogen dioxide sources are coal conversion processes, natural gas processing plants and natural gas compressor stations.

Health Effects
The negative effects of nitrogen dioxide on personal comfort, well being and the environment include respiratory distress, as well as impacts on vegetation, materials, visibility and acid deposition. Nitrate aerosols, which result from nitric oxide and nitrogen dioxide combining with water vapor in the air, consistently have been linked to visibility problems.

Standards Comparison
Nitrogen dioxide was monitored at seven sites. Five were operated by the department and two by industry.

The state annual standard (53 ppb) was not exceeded during the year. The maximum annual arithmetic mean of those sites collecting at least 80 percent of the possible data for the year was 6.5 ppb at Fargo NW.

The nitrogen dioxide data are summarized in Table 4.

*** Less than 80% of the possible samples (data) were collected.
Ammonia

Physical Characteristics
Ammonia is a corrosive, colorless gas with a strong irritating odor. It is used in making fertilizer, plastics, dyes, textiles, detergents and pesticides. It reacts with acids and oxidizing materials (fluorine, chlorine, etc.). It is corrosive to copper, zinc and many metal surfaces. It reacts with hypochlorite and halogens to form explosive compounds that are pressure and temperature sensitive.\(^6,7\)

Health Effects
In mild concentrations (<25 ppm), ammonia will cause conjunctivitis and dermatitis. At higher concentrations, in the eyes it will cause swelling, painful burns, lesions, and possible loss of vision. On contact with the skin, it will cause caustic-like burns and inflammation. Toxic level (300 ppm) skin exposure may cause skin lesions resulting in early necrosis and scarring. Inhalation is corrosive and irritating to the upper respiratory system and all mucus-type tissue. Depending on the concentration inhaled, it may cause burning sensations, coughing, wheezing, shortness of breath, headache and nausea, with eventual collapse and death.\(^6,7\)

Standards Comparison
There is no ambient air quality standard for ammonia. Because ammonia is important to the newer air quality dispersion models, the ammonia analyzer is maintained at the Beulah - North site.

The ammonia data are summarized in Table 5.

Ozone

Physical Characteristics and Sources

Ozone is a highly reactive form of oxygen. At very high concentrations, it is a blue, unstable gas with a characteristic pungent odor. It often can be detected around an arcing electric motor, lightning storms or other electrical discharges. However, at ambient concentrations, ozone is colorless and odorless.

At ground level where it can be breathed, ozone is a pollutant. However, ground-level ozone should not be confused with the stratospheric ozone located between 12 and 30 miles above the earth’s surface. The stratospheric ozone layer shields the earth from intense cancer-causing ultraviolet radiation. Concentrations of ozone in this layer are approximately 10,000 to 12,000 ppb or one hundred times the SAAQS for ozone. Occasionally, meteorological conditions can result in stratospheric ozone being brought to ground level. This can increase concentrations by 50 to 100 ppb.

Ozone is not emitted directly from a source like other pollutants, but forms as a secondary pollutant. Its precursors are certain hydrocarbons and nitrogen oxides that react chemically in sunlight to form ozone. The sources for these reactive hydrocarbons are automobile exhaust; gasoline and oil storage and transfer; industrial paint solvents; degreasing agents; cleaning fluids; and ink solvents. Nitrogen oxides are created when nitrogen and oxygen in the air combine during high-temperature combustion. Also, vegetation gives off some reactive hydrocarbons; for example, pine trees give off terpene.

Ozone production is a year-round phenomenon. However, the highest ozone levels generally occur during the summer season, when sunlight is stronger and stagnant meteorological conditions can cause reactive pollutants to remain in an area for several days. Ozone produced under these conditions can be transported many miles.

Health Effects

Short-term exposure to ozone in the range of 150 to 250 ppb may impair mechanical functions of the lungs and may induce respiratory difficulties and related symptoms in sensitive individuals (those who have asthma, emphysema or reduced lung function). Symptoms and effects of ozone exposure are more readily induced in people who are exercising.
Ozone is the major component of photochemical “smog,” although the haziness and odors of the smog are caused by other components. The deterioration and degradation of material, especially the splitting and cracking of rubber tires and windshield wiper blades, is associated with ozone. Many plants, such as soybeans and alfalfa, are sensitive to ozone and can be damaged by extended exposure to low levels of ozone.

Standards Comparison

Ozone was monitored at six state-run sites. This data is used in computer dispersion models as part of both the primary and secondary chemical transformation equations.

The 1-hour state standard (120 ppb) was not exceeded during the year. The maximum 1-hour concentration was 70 ppb at Fargo NW.

As part of preparing for a new 8-hour standard (80 ppb), 8-hour averages have been included in the data summary. The 8-hour standard uses the fourth highest daily maximum for comparison to the standard. The highest fourth-highest 8-hour concentration was 63 ppb at Fargo NW.

The ozone data are summarized in Table 6.

Particulate Matter (PM\textsubscript{2.5} & PM\textsubscript{10})

Physical Characteristics and Sources

Particulate matter is the term given to the tiny particles of solid or semi-solid material found in the atmosphere. Particulates ranging in size from less than 0.1 micrometer to 50 micrometers are called Total Suspended Particulate (TSP). Particles larger than 50 micrometers tend to settle out of the air quickly and are not considered to have a health impact. Particulate matter 10 micrometers in diameter and smaller is considered inhalable. This particulate matter is called PM\textsubscript{10}.\textsuperscript{10}

The majority of anthropogenic (man-made) particulate are in the 0.1 to 10 micrometer diameter range. Particles larger than 10 micrometers usually are due to “fugitive dust” (windblown sand and dirt from roadways, fields and construction sites) and contain large amounts of silica (sand-like) materials. PM\textsubscript{10} particulate, on the other hand, generally is created during a burning process and includes fly ash (from power plants), carbon black (from automobiles and diesel engines) and soot (from fireplaces and wood-burning stoves). PM\textsubscript{10} particulates from these sources contain a large percentage of elemental and organic carbon, which play a role in both visual haze and health issues.\textsuperscript{10}

In addition, particles less than 2.5 micrometers (PM\textsubscript{2.5}) are major contributors to visibility degradation because of their ability to “scatter” light.

Health Effects

The health risk from an inhaled dose of particulate matter depends on the size and concentration of the particulate. Size determines how deeply the inhaled particulate will penetrate into the respiratory tract, where it can persist and cause respiratory damage. Particles less than 10 micrometers in diameter are easily inhaled deeply into the lungs.

Fine particulate (PM\textsubscript{2.5}) pollution affects the health of certain subgroups. Such groups can be identified as potentially “at risk” of adverse health effects from air borne pollutants. There is very strong evidence that asthmatics are much more sensitive (i.e., respond with symptoms at relatively low concentrations) to the effects of particulates than is the general healthy population.\textsuperscript{9}

The effects of particulate exposure may be the most widespread of all pollutants. Because of the potential for extremely long-range transport of fine particles and because of the chemical reactions that occur, no place on earth has been spared from the particulate generated by
urban and rural sources. The effects of particulate range from visibility degradation to climate changes to vegetation damage. General soiling, commonly thought to be just a nuisance, can have long-term effects on paint and other materials. Acid deposition can be detected in the most remote areas of the world.

Inhalable PM\textsubscript{2.5} Particulates

Inhalable PM\textsubscript{2.5} particulates were monitored at seven sites operated by the department. Single-day samplers were installed at Beulah, Dickinson, Sharon, and TRNP - SU to collect a sample once every six days. Sequential samplers were installed at Bismarck, Fargo and Grand Forks to collect a sample once every three days.

Standards Comparison

The 24-hour federal standard (65 µg/m\textsuperscript{3}) was not exceeded during the year. The maximum 24-hour average concentration was 37.7 µg/m\textsuperscript{3} at Sharon.

The federal annual standard (15 µg/m\textsuperscript{3}) was not exceeded for the year. The maximum annual average was 8.1 µg/m\textsuperscript{3} at Grand Forks - North.

The inhalable PM\textsubscript{2.5} data are summarized in Table 7.

The maximum 24-hour concentration is 36.0 \(\mu g/m^3\) at Fargo NW on 01/03

* The ambient air quality standards are:
  - Federal Standards -
    1) 24-hour: 3-year average of 98th percentiles not to exceed 65 \(\mu g/m^3\).
    2) Annual: 3-year average not to exceed 15 \(\mu g/m^3\).

*** Less than 80% of the possible samples (data) were collected.

### Inhalable Continuous PM$_{2.5}$ Particulates

Inhalable particulates are monitored continuously at Beulah - North and Fargo NW. Since the data collected is not collected by an EPA reference or equivalent method, the data can not be used for standard comparison. The EPA is expected to designate the analyzers used as an equivalent method some time in 2002.

The maximum 1-hour average concentration was 151.4 \(\mu g/m^3\) at Fargo NW. The maximum 24-hour average concentration is 33.4 \(\mu g/m^3\) at Beulah North. The maximum annual average is 5.6 \(\mu g/m^3\) at Beulah - North.

The inhalable continuous PM$_{2.5}$ data are summarized in Table 8.
Table 8

The maximum 1-hour concentration is 151.4 µg/m$^3$ at Beulah - North on 03/28/13.
The highest 24-hour concentration is 29.7 µg/m$^3$ at Beulah - North on 03/28.

* The ambient air quality standards are:

1) **FEDERAL Standards** -
   1) 24-hour: 3-year average of 98th percentiles not to exceed 65 µg/m$^3$.
   2) Annual: 3-year average not to exceed 15 µg/m$^3$.

Inhalable PM$_{10}$ Particulates

Inhalable PM$_{10}$ particulate concentrations were monitored at three sites.

**Standards Comparison**

- The 24-hour state standard (150 µg/m$^3$) was not exceeded during the year. The maximum 24-hour concentration was 42.4 µg/m$^3$ at Fargo NW.
- The annual state standard (50 µg/m$^3$) was not exceeded. The maximum annual mean for the year was 16.8 µg/m$^3$ at Fargo NW.

The inhalable particulate (PM$_{10}$) data are summarized in Table 9

The maximum 24-hour concentration is 84.4 µg/m$^3$ at Bismarck Residential on 05/19.

* The **STATE air quality standards are**:

1) 150 µg/m$^3$ maximum averaged over a 24-hour period with no more than one expected exceedance per year.
2) 50 µg/m$^3$ expected annual arithmetic mean.
SUMMARY AND CONCLUSIONS

The state of North Dakota has relatively clean air. North Dakota is one of only 14 states to comply with all federal ambient air quality standards. The air quality in North Dakota also meets all state ambient air quality standards. Site and pollutant combinations that do not meet the 80 percent data recovery for the full year are reported as a partial year. A summary for each pollutant is provided below.

**Sulfur Dioxide**

The federal standards were not exceeded at any monitoring site. The state 1-hour standard was exceeded three times. The maximum concentrations and the maximum concentrations expressed as a percentage of the applicable standard are as follows: 1-hour – 164 ppb (60.1%); 3-hour – 116 ppb (23.2%); 24-hour – 38 ppb (38.4%); annual – 5.5 ppb (23.9%).

**Sulfur Dioxide 5-Minute Averages**

No standard is currently in effect. The maximum 5-minute average was 229 ppb.

**Nitrogen Dioxide**

Neither state nor federal standard was exceeded at any of the monitoring sites. The maximum concentration and the maximum concentration expressed as a percentage of the applicable standard is as follows: annual – 6.5 ppb (12.3%).

**Ammonia**

No standard is currently in effect. The maximum 1-hour average is 110.0 ppb.

**Ozone**

Neither state nor federal standards were exceeded during the year. The maximum 1-hour concentration and the maximum 1-hour concentration expressed as a percentage of the applicable standard is 70 ppb (58.3%). The fourth highest 8-hour average concentration was 63 ppb (78.8%).
Inhalable PM$_{2.5}$ Particulates

The federal standards were not exceeded during the year. The maximum concentrations and the maximum concentrations expressed as a percentage of the applicable standard are as follows: 24-hour – 36.0 μg/m$^3$ (55.4%); annual – 8.3 μg/m$^3$ (55.3%).

Inhalable Continuous PM$_{2.5}$ Particulates

No standard is currently in effect for this analytical method. The maximum 1-hour average was 151.4 μg/m$^3$. The maximum 24-hour average was 29.7 μg/m$^3$. The maximum annual average was 6.8 μg/m$^3$.

Inhalable PM$_{10}$ Particulates

The state standards were not exceeded during the year. The maximum concentrations and the maximum concentrations expressed as a percentage of the applicable standard are as follows: 24-hour – 84.4 μg/m$^3$ (56.3%); annual – 20.2 μg/m$^3$ (40.4%).

APPENDICES
APPENDIX 1

North Dakota and Federal Ambient Air Quality Standards
STANDARDS

In general, air pollutants are divided into two classes: primary pollutants such as sulfur dioxide, carbon monoxide, nitrogen dioxide, hydrogen sulfide, particulate matter (<2.5 microns) and particulate matter (<10 microns) and secondary pollutants which are formed as the result of a chemical reaction. Sources of primary pollutants include power plants, natural gas processing plants, oil wells, oil refineries, asphalt plants, factories, wind-blown dirt, automobiles, fireplaces and incinerators. Secondary pollutants result from a primary pollutant undergoing a chemical reaction; for example, ozone is formed as a result of a photochemical reaction between hydrocarbons and oxides of nitrogen.

The North Dakota Ambient Air Quality Standards are established to protect public health and welfare. Effective Aug. 1, 1997, coal conversion and oil refineries were exempted from the state sulfur dioxide standards.

Table A1-1 presents the current North Dakota Ambient Air Quality Standards. Table A1-2 presents the federal Ambient Air Quality Standards. State standards must be as stringent as (but may be more stringent than) federal standards.

APPENDIX 3

Wind and Pollution Star Charts
The figures in this appendix are arranged with the site’s wind star chart in the upper left-hand position. To remove most of the wind direction bias caused by low wind speeds, wind speeds less than 5 mph were removed from the data. For department-operated sites the pollution star charts are arranged with sulfur dioxide in the upper right-hand position. Next is either hydrogen sulfide or nitrogen dioxide. For industry networks, the wind star chart is presented first followed by the parameters monitored at each site. Except for the Bear Paw - McKenzie Gas Plant network which has wind direction at each site, there is only one MET station for each network.

The pollution star charts present the percentage of time a pollutant is detected when the wind is from a given direction. For example, a wind star chart shows a frequency of 122, and a pollution star chart shows a 66 for the same direction. This means that 66 percent of the time (80 of the possible 122 hours) the wind was greater than 5 mph from that direction and an hourly average for that pollutant had a detectable concentration.

Ozone pollution star charts are not presented because the percentage of time would be essentially 100 percent for each wind sector.
