Terry O'Clair, Director  
Division of Air Quality  
ND Department of Health  
P.O. Box 5520  
Bismarck, ND 58506-5520

Dear Mr. O'Clair:

Thank you for submitting the 2003 North Dakota Network Review (NR) received July 12, 2004. In general, the NR addresses all parameters adequately. Thus, the NR meets the 40 CFR, Part 58 requirement and the 105 grant commitment to conduct a review annually. Please have your staff review the enclosed comments. The comments do not require further action.

If you or your staff has any questions regarding the NR comments or need further assistance, contact your EPA Region VIII state monitoring contact, Deirdre Rothery at 303-312-6431.

Sincerely Yours,

A handwritten signature in blue ink, appearing to read "Richard R. Long".

Richard R. Long, Director  
Air and Radiation Program

cc: Dan Harman, North Dakota DAQ

Enclosure

## **Enclosure**

### **Comment 1:**

The Network Review states the air toxics 2003 monitoring data has not yet been entered into AQS, it appears the data has since been loaded by ERG.

### **Comment 2:**

As a follow-up to Comment 3 in the 2002 Network Review response letter, EPA acknowledges the redesignating of North Dakota's three non-CORE required, population based sites, to Beulah, Bismarck and Fargo additionally, Dunn Center will serve as a regional background site and TRNP-NU as a regional transport site.

### **Comment 3:**

As a follow-up to Comment 4 in the 2002 Network Review response letter, EPA acknowledges the reporting of TRNP-SU ozone and PM<sub>2.5</sub> data to AIRNOW. EPA looks forward to the reporting of additional sites to AIRNOW in the near future.

Re: FY '02-'03 PPA, Air Quality  
Media Workplan, Monitoring,  
Item B (Network Review)

Dear Ms. Rothery:

An electronic copy of the enclosed referenced review was e-mailed to you June 24, 2004. Due to the pending update to 40 CFR 58, it is not practical for us to consider any major network changes. An additional site previously discussed for TRNP-SU is still in the discussion stage.

Because this review is based on a calendar year, it does not include any network changes we may have discussed: these changes will be addressed in the 2005 network modification plan and included in next year's network review.

If you have any questions about the review, please contact me by e-mail at [dharman@state.nd.us](mailto:dharman@state.nd.us) or phone at 701-328-5188.

Sincerely,

Daniel E. Harman

## 1.0 INTRODUCTION

The North Dakota Department of Health, Division of Air Quality, has the primary responsibility of protecting the health and welfare of North Dakotans from the detrimental effects of air pollution. Toward that end, the Division of Air Quality ensures that the ambient air quality in North Dakota is maintained in accordance with the levels established by the state and federal Ambient Air Quality Standards (AAQS) and the Prevention of Significant Deterioration of Air Quality (PSD) Rules. To carry out this responsibility, the Division of Air Quality operates and maintains a network of ambient air quality monitors and requires three major industrial pollution sources to conduct source specific ambient air quality monitoring.

To evaluate the effectiveness of the State's air quality monitoring effort, the U.S. Environmental Protection Agency (EPA) requires the Division of Air Quality to conduct an annual review of the State's ambient air quality monitoring (AAQM) network. EPA's requirements, as set forth in 40 CFR 58.20, are to (1) determine if the system meets the monitoring objectives defined in 40 CFR 58, Appendix D, and (2) identify network modifications such as termination or relocation of unnecessary sites or establishment of new sites which are necessary. 40 CFR 58.25 requires the state to annually develop and implement a schedule to modify the AAQM network to eliminate any unnecessary sites or correct any inadequacies indicated as a result of the annual review required by 40 CFR 58.20(d). This document and subsequent revisions satisfy these annual requirements.

### 1.1 Network Review Process

*The locations of sites in a monitoring program are established to meet certain objectives. The May 10, 1979, Federal Register (40 CFR 58), "Ambient Air Quality Surveillance Regulations," as amended, has specified a minimum of six basic monitoring objectives. These objectives are as follows:*

1. *To determine the highest pollutant concentrations expected to occur in an area covered by the network.*
2. *To determine representative concentrations in areas of high population density.*
3. *To determine the impact on ambient pollution levels by a significant source or class of sources.*
4. *To determine the general/background concentration levels.*
5. *To determine the impact on air quality by regional transport.*
6. *To determine Welfare-related impacts.*

The link between basic monitoring objectives and the physical location of a particular monitoring site involves the concept of spatial scale of representativeness. This spatial scale

is determined by the physical dimensions of the air parcel nearest a monitoring site throughout which actual pollutant concentrations are reasonably similar. The goal in locating sites is to match the spatial scale represented by the sample of monitored air with a spatial scale most appropriate for the monitoring objective. Spatial scales of representativeness, as specified by EPA, are described as follows:

Microscale - dimensions ranging from several meters up to about 100 meters.

Middle Scale - areas up to several city blocks in size with dimensions ranging from about 100 meters to 0.5 km.

Neighborhood Scale - city areas of relatively uniform land use with dimensions of 0.5 to 4.0 km.

Urban Scale - overall, city-wide dimensions on the order of 4 to 50 km. (Usually requires more than one site for definition.)

Regional Scale - rural areas of reasonably homogeneous geography covering from 50 km to hundreds of km.

The relationships between monitoring objectives and spatial scales of representativeness, as specified by EPA, are as follows:

<u>Monitoring Objective</u>	<u>Appropriate Siting Scales</u>
Highest Concentration	Micro, middle, neighborhood
Population Exposure	Neighborhood, urban
Source Impact	Micro, middle, neighborhood
General/Background	Urban, regional
Regional Transport	Urban, regional
Welfare-related Impacts	Urban, regional

Recommended scales of representativeness appropriate to the criteria pollutants monitored in North Dakota are shown below:

<u>Criteria Pollutant</u>	<u>Spatial Scales</u>
Inhalable Particulate (PM <sub>10</sub> )	micro, middle, neighborhood, urban, regional
Sulfur Dioxide (SO <sub>2</sub> )	middle, neighborhood, urban, regional
Ozone (O <sub>3</sub> )	middle, neighborhood, urban, regional
Nitrogen Dioxide (NO <sub>2</sub> )	middle, neighborhood, urban
Carbon Monoxide (CO)	micro, middle, neighborhood

Using this physical basis to locate sites allows for an objective approach, ensures compatibility among sites, and provides a common basis for data interpretation and application. The annual review process involves an examination of existing sites to evaluate their monitoring objectives and spatial scale with sites deleted, added, or modified accordingly. Further details on network design can be found in 40 CFR 58, Appendix D.

## 1.2 General Monitoring Needs

As can be gathered from the prior discussion, each air pollutant has certain characteristics which must be considered when establishing a monitoring site. These characteristics may result from 1) variations in the number and types of sources and emissions in question; 2) reactivity of a particular pollutant with other constituents in the air; 3) local site influences such as terrain and land use; and 4) climatology. The State AAQM network is designed to monitor air quality data for four basic conditions: 1) background monitoring; 2) population exposure; 3) highest concentration; and; 4) long range transport/regional haze. Industrial AAQM network sites are designed to monitor air quality data for source specific highest concentration impacts on an urban scale. Tribal network sites and data are included in this review even though there is only minimal influence on the network operation.

The primary function of the department's four required sites (see Table 1) are to satisfy the six monitoring objectives. Beulah is source impact and population exposure because of the major sources in the vicinity of Beulah. The site is a combination of a down-wind site and between the city and two major source. Fargo NW is population orientated because Fargo is a major population center with PSD sources in the Fargo-Moorhead area. The data from this site is used as input to dispersion models to evaluate permits-to-construct and permits-to-operate for projects located in or near population centers in the eastern part of the state. Dunn Center is the background site. And, TRNP-NU is the regional transport site. The remaining sites are used to support modeling and/or supplement data collected at the required sites.

Before the next network modification plan is completed in January 2005, the need for several sites/parameter combinations will be reviewed. The current list of existing sites/parameters to be reviewed are Bismarck Residential SO<sub>2</sub> and NO<sub>x</sub>. Consideration is being given to opening a site at TRNP - SU along the eastern boundary of the park. If approved, the site will have SO<sub>2</sub>, NO<sub>x</sub>, O<sub>3</sub>, continuous PM<sub>10</sub> and PM<sub>2.5</sub>, WS, WD, Temperature, Delta Temperature, and Solar Radiation.

Background sites are chosen to determine concentrations of air contaminants in areas remote from urban sources and generally are sited using the regional spatial scale. This is true for NO<sub>2</sub> despite the fact that the regional spatial scale is not normally used for NO<sub>2</sub> monitoring. Once a specific location is selected for a site, monitoring sites are established in accordance with the specific probe siting criteria specified in 40 CFR 58, Appendix E.

Since all industrial AAQM network sites are source specific, all the pollutants at industry sites are source oriented on an urban scale. Industrial sites are initially selected using dispersion modeling results and meteorological data. If a particular location is determined not to be practical due to, for example, inaccessibility or power not reasonably available, then sites in a prevailing wind direction are considered. These sites are the most likely locations to have elevated ambient concentrations. The data collected at the industry-operated sites is included in the data summaries for comparison but not included in any discussion of the State ambient monitoring network needs or analysis. Each industry network is an entity unto itself and does not influence the placement of State operated sites.

The Fort Berthold Indian Reservation operates an ambient air quality monitoring network. Since the Department has influence on neither the operation nor maintenance of the network, the data collected are included only to indicate the presence of the sites. The data validity is not certified by inclusion.

The Fort Totten Indian Reservation is in the process of evaluating the need for an ambient air monitoring network along with what parameters and how many sites may be needed. If they establish a network with acceptable quality assurance, the data will be included in our data summaries.

### 1.3 Monitoring Objectives

The monitoring objectives of the Department are to track those pollutants that are judged to have the potential for violating either State or Federal Ambient Air Quality Standards and to ensure that those pollutants do not cause significant deterioration of our existing air quality. To accomplish these objectives, the Department operated nine AAQM sites around the State. Eight were SLAMS sites, and two were special purpose monitoring (SPM) sites. There were three industries reporting ambient air quality data to this Department. Table 1 lists each site's type and the parameters monitored. Figure 1 shows the approximate site locations. For the industry networks, each network is represented by a single circle whether there is a single site or multiple sites.

The numbers in the Site Name/Company column in Table 1 and in the '#' column in Tables 2, 5, 7, 9, 14, and 15 correspond to the numbers on the figures. The numbers in the circles correspond to the monitoring site monitoring that pollutant and the squares correspond to the major sources for that particular pollutant.

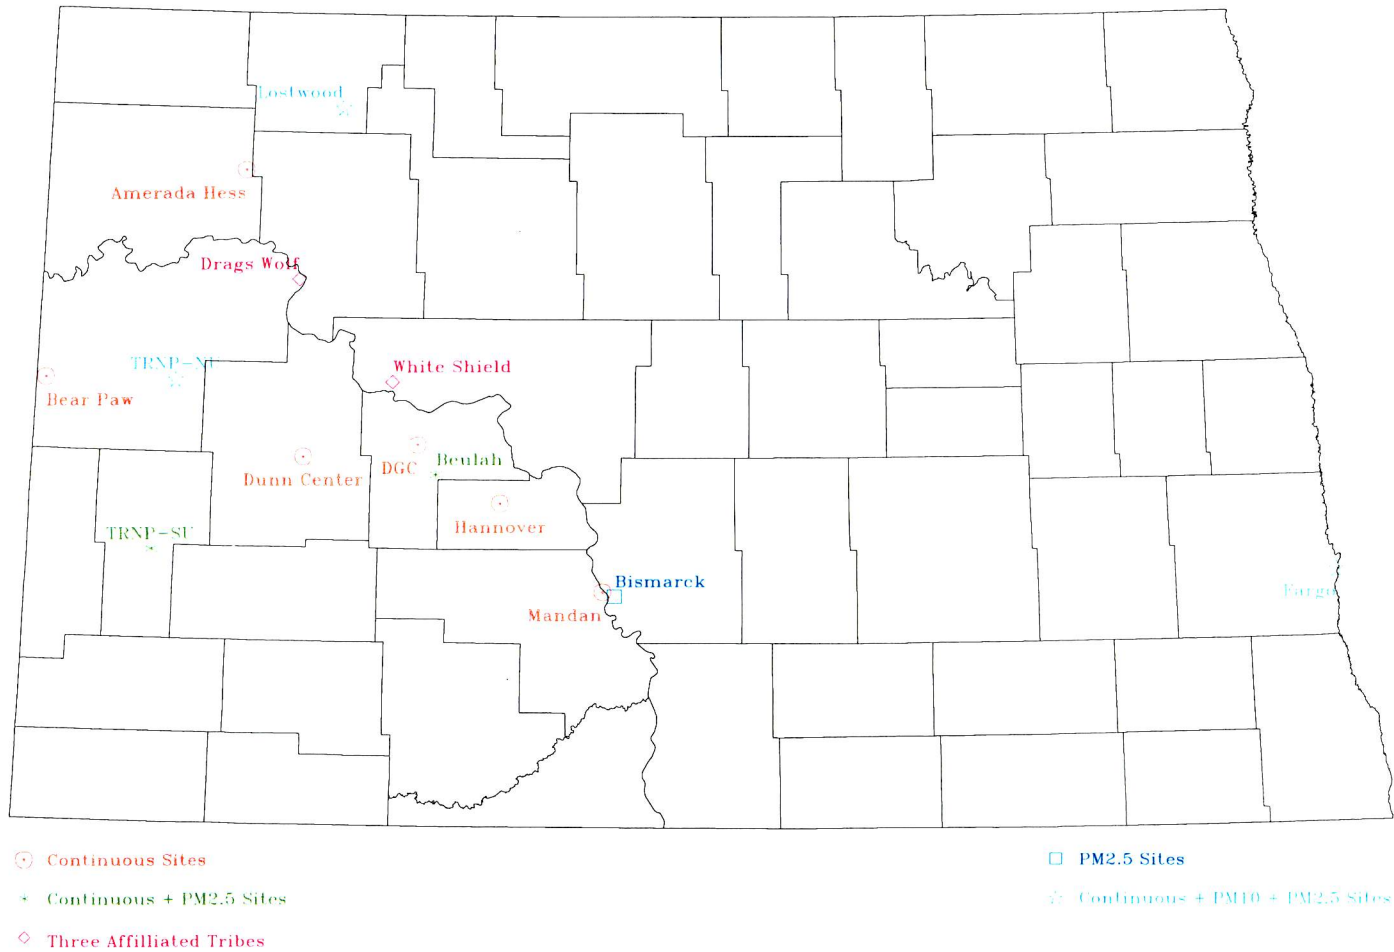

Figure 1 North Dakota Ambient Air Quality Monitoring Sites

## 2.0 AMBIENT AIR MONITORING NETWORK COVERAGE

The state of North Dakota is attainment for all criteria pollutants. As such, there are no "problem areas" in the general sense of the term. However, there are areas of concern where the Department has established monitoring sites to track the emissions of specific pollutants from point sources. Also, three major sources maintained monitoring networks in the vicinity of their plants (see Table 1 and Figure 1).

### 2.1 Sulfur Dioxide

Energy development in the west and west-central portions of North Dakota has produced a number of sources of sulfur dioxide (SO<sub>2</sub>). These sources include coal-fired steam-powered electrical generating facilities, a coal gasification plant, natural gas processing plants, an oil refinery, and flaring at oil/gas well sites. As a result, SO<sub>2</sub> is one of the Department's major concerns in regard to ambient air quality monitoring.

#### 2.1.1 Point Sources

The major SO<sub>2</sub> point sources (>100 TPY) are listed in Table 2 along with their emissions from the emissions inventories reported to the Department. Figure 2 shows the approximate locations of these facilities (the numbers correspond to the site and source tables). Figure 2A shows the contribution of point sources to the total SO<sub>2</sub> emissions.

#### 2.1.2 Other Sources

The western part of the State has a number of potential SO<sub>2</sub> sources associated with the development of oil and gas. These sources include individual oil/gas wells, oil storage facilities, and compressor stations. Emissions from such sources can create two problems. First, these sources may directly emit significant amounts of hydrogen sulfide (H<sub>2</sub>S) to the ambient air (see Section 2.7). Second, flaring the H<sub>2</sub>S from these sources can create significant concentrations of SO<sub>2</sub> in the ambient air. The primary counties for these sources in western North Dakota are outlined in green on Figure 2. Figure 2A shows the contribution of "Other Point Sources" that consists of DGC, refineries, gas processing plants, and agriculture processing plants.

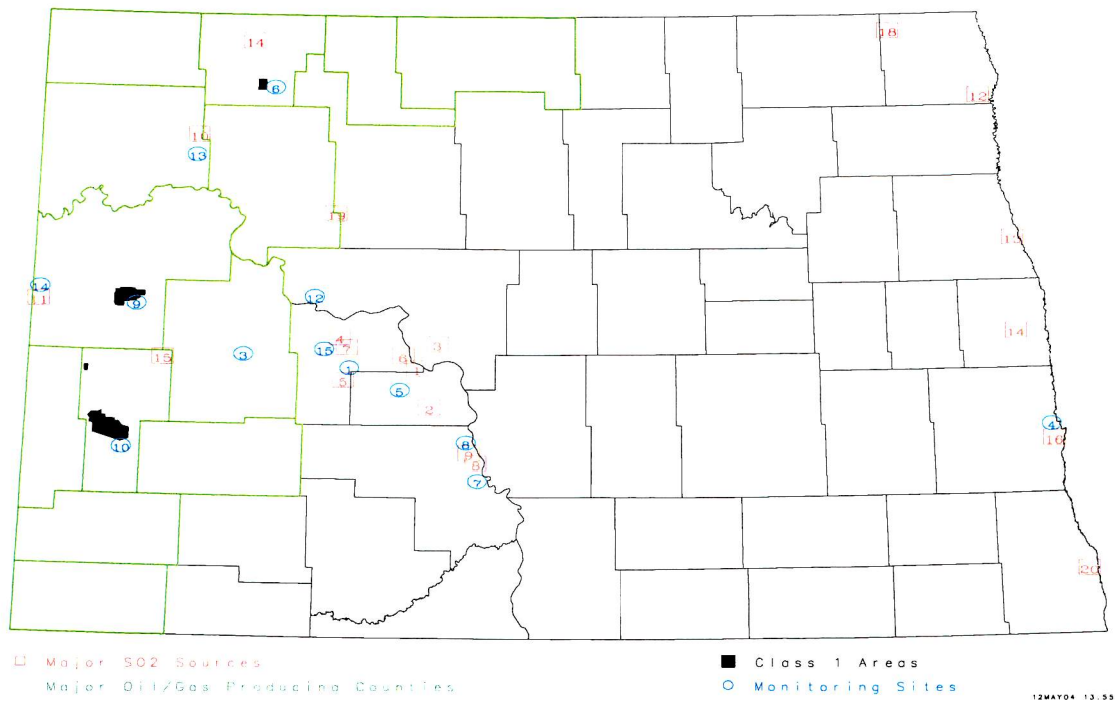

Figure 2 Major Sulfur Dioxide Sources

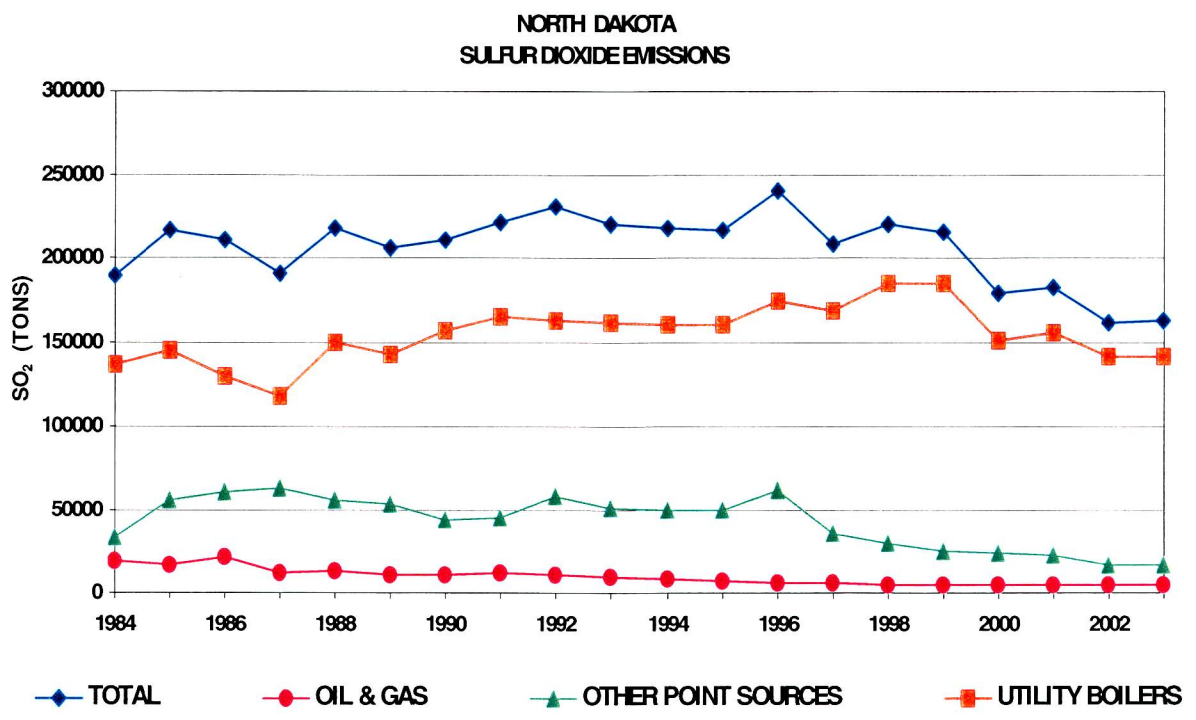

Figure 2A Annual Sulfur Dioxide Emissions

### 2.1.3 Monitoring Network

The SO<sub>2</sub> monitoring sites are shown on Figure 2. As can be seen, these monitoring sites are concentrated in the vicinity of the oil and gas development in the west and the coal-fired steam electrical generating plants in the west-central part of the State. Table 3 shows the 2003 annual SO<sub>2</sub> data summaries; Table 4 shows the 5-minute data summary. There were no exceedances of either state or federal SO<sub>2</sub> standards.

### 2.1.4 Network Analysis

The nine largest SO<sub>2</sub> sources in the state are within 45 miles of both the Beulah and Hannover sites. This makes these two sites very important in tracking the impact of these nine sources on the ambient air. One would expect that as the large sources came on line, beginning in 1980, a noticeable change would be seen on the ambient air quality. This has not been the case. There have been possible short term influences, but no significant long term impact by these nine sources combined. Figures 3, 4, 5, and 6, present a 24-year view of the percentage of data greater than the minimum detectable value (MDV), 1-hour maximums, 3-hour maximums, and 24-hour maximums, for the state-operated sites (except for Lostwood, which started Oct 28). Because the industry sites are sited specifically for maximum expected concentrations (primarily as predicted by dispersion models and secondarily in a downwind direction), the industry sites are not reviewed for particular long term trends.

The best long term indicator of any change in the amount of SO<sub>2</sub> in the ambient air is seen by reviewing the percentages of data points greater than the MDV. Figure 3 presents this data for the active state sites from 1980 through 2003. To calculate valid annual statistics, at least 75% of the data must be greater than the MDV. Therefore, the annual mean is not a valid indicator and, consequently, not addressed.

The maximum 5-minute concentration is 385 ppb at Bear Paw - MGP #3 on 07/24:10

\* No Standard is currently in effect:

Beginning in 1980, major events are easily traceable. In 1980, the oil industry was expanding. In 1981, Otter Tail Power's Coyote Power Station began operation. In 1982 the oil industry in western North Dakota hit its peak activity. 1983, 1984, and 1985 were startup years for Basin Electric's Antelope Valley Unit #1, the synthetic natural gas plant (aka, Dakota Gasification Company), and Antelope Valley Unit #2, respectively. From 1987 through 1993, for the Beulah and Hannover sites, there was a steady increasing trend in the percentage of data greater than the MDV. However, Hannover showed a decrease from 1993 to 1997 while Beulah continued to increase until 1997. The Beulah - N site began operation in 1998 and has shown a decreasing trend in percentage detectable.

The same patterns seen in Figure 3 are discernable in the 1-hour, 3-hour, and 24-hour maximum concentration graphs (see Figures 4, 5, and 6, respectively). As can be seen from the graphs, in 1998, the Mandan Refinery - SPM site exceeded the state and nearly the Federal 24-hour standard (see Figure 6): The 24-hour average was 143 ppb.

Because the newer sites ( Fargo NW, Mandan Refinery - SPM, Mandan Refinery NW - SPM, and TRNP - SU) have a limited amount of data, no attempt is made to evaluate the results.

## 2.2 Oxides of Nitrogen

Oxides of Nitrogen ( $\text{NO}_x$ ) is the term used to represent both nitric oxide (NO) and nitrogen dioxide ( $\text{NO}_2$ ).  $\text{NO}_2$  is formed when NO is oxidized in the ambient air. There are no ambient air quality standards for NO.

### 2.2.1 Point Sources

The major  $\text{NO}_x$  stationary point sources (>100 TPY) are listed in Table 5 along with their emissions as calculated from the most recent emission inventories reported to the department. Figure 7 shows the approximate locations of these facilities (the numbers correspond to the site and source tables). The larger  $\text{NO}_x$  point sources in North Dakota are associated with coal-fired steam-powered electrical generating plants in the west-central portion of the State and large internal combustion compressor engines in the natural gas fields in the western part of the State. Figure 7A shows the contribution of point sources to the total  $\text{NO}_2$  emissions. The "Point Sources" category consists of Utility Boilers (power plant boilers) and oil and gas wells.

### 2.2.2 Area Sources

Another source of  $\text{NO}_x$  is automobile emissions. North Dakota has no significant urbanized areas with regard to oxides of nitrogen; the entire population of the State is less than the 1,000,000 population figure that EPA specifies in the  $\text{NO}_2$  requirement for NAMS monitoring. Figure 7A shows the contribution of "Other Point Sources" and "Utility Boilers." The "Other Point Sources" category consists of DGC, refineries, gas processing plants, and agriculture processing plants.

### 2.2.3 Monitoring Network

The Department currently operates six NO/ $\text{NO}_2$ / $\text{NO}_x$  analyzers. These are located at Beulah, Dunn Center, Fargo, Hannover, Lostwood NWR, and TRNP - NU. The Dakota Gasification Company (DGC) network also operates analyzers at sites DGC #12 and DGC #17. Table 6 shows the 2003  $\text{NO}_2$  data summaries. The measured  $\text{NO}_2$  values are quite low, particularly the annual means. From Figure 7 it can be seen that NO/ $\text{NO}_2$ / $\text{NO}_x$  analyzers, except for Dunn Center and TRNP - NU, are well placed with respect to the major  $\text{NO}_x$  sources: Dunn Center and TRNP - NU are defined as a background site and long range transport/regional haze, respectively.

The maximum 1-hour concentration is 48 ppb at Fargo NW on 10/06:18

\* The air quality standards are:  
STATE - 53 ppb maximum annual arithmetic mean.  
FEDERAL - 53 ppb annual arithmetic mean.

\*\*\* Less than 80% of the possible samples (data) were collected.

#### 2.2.4 Network Analysis

Nine of the ten largest NO<sub>2</sub> sources in the state are within 45 miles of the Beulah and Hannover monitoring sites. Figures 8 and 9 show the trends for the state operated sites for 1980 - 2003. Since the industry operated sites are placed for maximum concentrations, trends are not considered.

With the exception of Beulah in 1981, the percentage of data greater than the MDV, shown in Figure 8, was reasonably stable until 1993. The significant increase in the percentage of detectable concentrations is contrary to the quantity of NO<sub>2</sub> emitted. Figure 7A show an increasing, but slow, trend in NO<sub>2</sub> emissions from 1984 until 1992. From 1993 until present, there has been a decreasing trend in NO<sub>2</sub> emissions. A possible explanation for Hannover is the analyzer was changed in March 1992 from a Meloy 8101C to a TECO 42. However, the analyzer change did not produce a discreet jump: the increase was seen at both the Beulah and Hannover sites. A possible conclusion is the increase in detectable NO<sub>2</sub> concentrations is real and not the result of equipment changes. Another possibility, and more likely, is a change in the wind flow patterns. In 2000, Dunn Center and Hannover were the only sites that had a decrease in the number of hourly averages less than the minimum detectable value.

If the annual average concentrations had followed a pattern similar to the one shown in Figure 8, the equipment change could have accounted for the increase in the percentage of data greater than the MDV. However, the annual averages, shown in Figure 9, have shown no particular trend. Since TRNP-NU is a relatively new site, no valid trending is possible.

Figure 8 Percentage of Time NO<sub>2</sub> Detectable

Figure 9 NO<sub>2</sub> Annual Average Concentrations

## 2.3 Ozone

Unlike most other pollutants, ozone ( $O_3$ ) is not emitted directly into the atmosphere but results from a complex photochemical reaction between volatile organic compounds (VOC), oxides of nitrogen ( $NO_x$ ), and solar radiation. Both VOC and  $NO_x$  are emitted directly into the atmosphere from sources within the State. Since solar radiation is a major factor in  $O_3$  production,  $O_3$  concentrations are known to peak in summer months. 40 CFR 58 defines the  $O_3$  monitoring season for North Dakota as May 1 through September 30. However,  $O_3$  analyzers at all sites collect data year round for use in dispersion modeling.

### 2.3.1 Point Sources

The major stationary point sources (> 100 TPY) of VOC, as calculated from the most recent emission inventories reported to the Department, are listed in Table 7. Figure 10 shows the approximate locations of these facilities.

### 2.3.2 Area Sources

Point sources contribute only part of the total VOC and  $NO_x$  emissions. The remaining emissions are attributed to mobile sources in urban areas. The EPA has specified a design criteria for selecting NAMS locations for  $O_3$  as any urbanized area having a population of more than 200,000. North Dakota has no urbanized areas large enough to warrant population-oriented monitoring.

TABLE 7

Major VOC Sources  
(> 100 TPY)

2003

#	Company	Source	Pollutant Emission	Percentage of Total		Facility ID

The maximum 1-hour concentration is 83 ppb at TRNP - NU on 08/16  
The 4th highest 8-hour concentration is 71 ppb at TRNP - NU on 08/13

\* The air quality standards for ozone are:  
STATE - 120 ppb not to be exceeded more than once per year.

FEDERAL Standards -

- 1) 120 ppb maximum 1-hour concentration with no more than one expected exceedance per year.
- 2) Fourth highest daily maximum 8-hour averages for a 3-year period not to exceed 80 ppb.

\*\*\* Less than 80% of the possible samples (data) were collected

### 2.3.3 Monitoring Network

The state currently has seven continuous ozone analyzers in operation. These are at Beulah, Dunn Center, Fargo, Hannover, Lostwood NWR, Theodore Roosevelt National Park - North Unit, and Theodore Roosevelt National Park - South Unit. Table 8 presents 2002 1-hour and 8-hour data summaries. Figure 11 shows the maximum 8-hour averages by month for 2003.

Figure 11 Monthly Maximum Ozone Concentrations

### 2.3.4 Network Analysis

Only two of the seven monitoring sites are in an area not significantly influenced by VOC sources (see Figure 10). Beulah and Hannover are within 45 miles of seven of the ten major VOC sources in the state. Lostwood NWR, TRNP - NU and TRNP-SU are located in a Class I area surrounded by oil fields. Fargo NW is located in Fargo and influenced by city traffic. Dunn Center is located in a rural area surrounded by crop land. With this diversity of site locations and influences, one would expect to see a diversity of ozone concentrations. On the contrary, Figure 12 shows a significant similarity among the maximum 1-hour concentrations. Since 1980, there have been only five hours of data collect higher than 80 ppb and none of these exceeded 100 ppb. Another, even stronger, indication of a uniform ozone distribution is the 8-hour concentrations: for all sites, the difference between the highest and 4<sup>th</sup> highest concentrations are within 9 ppb (see Table 8).

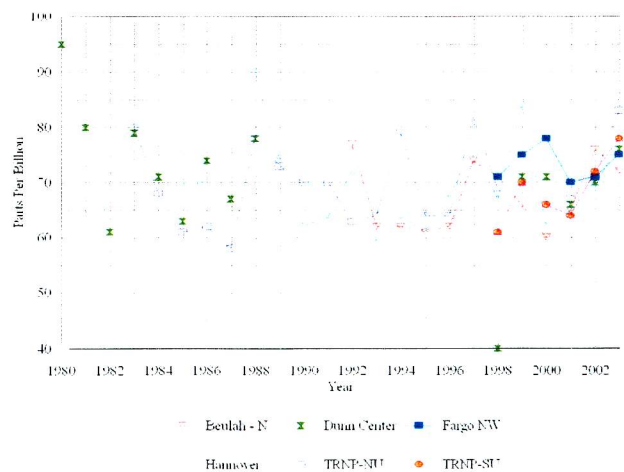

Figure 12 Annual Maximum Ozone Concentrations

## 2.4 Inhalable Particulates

The inhalable particulate standards are designed to protect against those particulates that can be inhaled deep into the lungs and cause respiratory problems. The major designation for inhalable particulates is PM. Within this designation are two subgroups: PM<sub>10</sub> and PM<sub>2.5</sub>. The PM<sub>10</sub> particulates have an aerodynamic diameter less than or equal to a nominal 10 microns and are designated as PM<sub>10</sub>. The PM<sub>2.5</sub> particulates have an aerodynamic diameter less than or equal to a nominal 2.5 microns and are designated as PM<sub>2.5</sub>.

### 2.4.1 Sources

The major PM<sub>10</sub> point sources (>100 TPY) are listed in Table 9 along with their emissions as calculated from the most recent emissions. Figure 13 shows the approximate locations of these facilities (the numbers correspond to the site and source tables). Most of these sources are large coal-fired facilities, and the PM<sub>10</sub> particles are part of the boiler stack emissions; However, some of the emissions are the result of processing operations. Not included in this table are sources of fugitive dust such as coal mines, gravel pits, agricultural fields, and unpaved roads. Figure 13A shows the contribution of point sources to the total PM<sub>10</sub> emissions. The “Utility Boilers” category consists of power plant boilers. The “Other Point Sources” category consists of DGC, refineries, gas processing plants, and agriculture processing plants.

### 2.4.2 Monitoring Network

The State operates three PM<sub>10</sub> samplers, five FRM PM<sub>2.5</sub> samplers, and three speciation samplers. Data from the two Three Affiliated Tribes sites, Dragswolf and White Shield, are included for informational purposes only. Tables 10 and 12 show the inhalable PM<sub>10</sub> and continuous particulate data summaries, respectively. Tables 11 and 13 show the FRM PM<sub>2.5</sub> and continuous particulate data summaries, respectively.

R&P single-day samplers are installed at Beulah, TRNP - SU, and TRNP - NU. And, R&P sequential samplers were installed at Bismarck and Fargo.

2) Annual: 3-year average not to exceed 15 µg/m<sup>3</sup>.

### 2.4.3 PM<sub>10</sub> Network Analysis

Since PM<sub>10</sub> and smaller particles are of concern mainly because of their effects on people, two sites are located in population centers, Bismarck and Fargo. Two sites, Lostwood NWR and TRNP - NU, are in Class I areas, which are used for background data. The intent is to replace the manual samplers at Fargo and TRNP - NU with continuous PM analyzers as 103 funding becomes available. This transition is planned to be completed during 2004.

#### 2.4.4 PM<sub>2.5</sub> Network

The manual PM<sub>2.5</sub> network currently has five sites. Bismarck, Fargo and Beulah are non-CORE required sites. Bismarck and Fargo operate on a 1-in-3 day schedule while Beulah, TRNP - SU and TRNP - NU operate on a 1-in-6 day schedule. Between June 29 and July 5, all the WINS impactors were replaced with the SSC cyclones. We expect this change to reduce the cooler ambient temperature influence on impactor oil jelling or crystalizing. Continuous PM<sub>2.5</sub> analyzers (TEOMs) have been installed at Beulah, Fargo, Hannover, Lostwood NWR, TRNP-NU, and TRNP-SU.

The intent of the TEOMs is to begin using these analyzers as the primary data source and use a FRM/FEM sampler only for quality assurance purposes. As the PM<sub>2.5</sub> samplers are replaced or removed from service, some will be converted to PM<sub>10</sub> samplers and used along with speciation samplers to collect a data set comparable to the IMPROVE samplers. This is expected to provide data that can be used in the regional haze/visibility determinations.

Our initial work to compare the internal TEOM data with the manual sampler data has not met with much success. So far the best R<sup>2</sup> has been 0.74. A major contributing factor may be the date in two TEOM's internal was off by two days. Since the internal data is not used for reporting, the only effect was to cause a poor correlation.

#### 2.4.5 Speciation Network

Speciation samplers are installed in Bismarck, TRNP - NU, and a National Trends Network sampler in Fargo. The goal of the two state-selected sites is to supplement the data collected by the two IMPROVE samplers: TRNP - SU and Lostwood NWR. With the combined data, it is expected the Department will be able to make a better assessment of the current visibility and track improvement over time. The data collected is added to the AQS database by RTI.

### 2.5 Carbon Monoxide

Many large urban areas in the United States have problems attaining the NAAQS for carbon monoxide (CO) where the primary source of CO is automobiles. North Dakota does not have sufficient population with the corresponding traffic congestion and geographical/meteorological conditions to create significant CO emission problems. However, there are several stationary sources in the State that emit more than 100 TPY of CO.

#### 2.5.1 Sources

The major stationary CO sources (>100 TPY) are listed in Table 14 along with their emissions as calculated from the most recent emissions inventories reported to the department. Figure 20 shows the approximate locations of these facilities (the numbers correspond to the site and source tables). Most of these sources are the same sources that are the major emitters of SO<sub>2</sub> and NO<sub>x</sub>. However, the corresponding CO levels from these sources are considerably lower.

#### 2.5.2 Monitoring Network

Carbon monoxide monitoring in North Dakota was terminated March 31, 1994, after 5 years of operation. The conclusion drawn from the data was that North Dakota did not have a CO problem. A summary report of the data collected at the West Acres Shopping Mall was drafted for the Fargo-Moorhead Council of Governments for use in their traffic planning program.

TABLE 14

Major CO Sources  
(> 100 TPY)

2003

#	Company	Source	Pollutant Emission	Percentage of Total Emissions	Facility ID
1	Great River Energy - CCS	Coal Creek Station	1996	18.71%	3805500017
2	Dakota Gasification Co.	Plant	1861	17.45%	3805700013

14	University of North Dakota	Heating Plant	142	1.33%	3803500003
15	Bear Paw Energy,LLC	Alexander	119	1.11%	3805300024
16	Great River Energy	Stanton Station	118	1.11%	3805700004
17	ADM Corn Processing	Ethanol Plant - Walhalla	118	1.10%	3806700004

Figure 14 Major CO Sources

## 2.6 Lead

Through prior sampling efforts, the Department has determined that the State has low lead concentrations (38.6% of the standard) and no significant lead sources. This determination, coupled with the Federal requirement for a NAMS network only in urbanized areas with populations greater than 500,000, resulted in terminating the lead monitoring program effective December 31, 1983. Along with the low monitored concentrations, lead has been completely removed from gasoline since lead monitoring began in 1979.

## 2.7 Hydrogen Sulfide

Although no Federal Ambient Air Quality Standard exists for hydrogen sulfide ( $H_2S$ ), the State of North Dakota has developed  $H_2S$  standards.

### 2.7.1 Sources

H<sub>2</sub>S emissions of concern stems almost totally from the oil and gas operations in the western part of the State; principally from the green outlined area on Figure 2. Flares and treater stacks associated with oil/gas wells, oil storage tanks, compressor stations, pipeline risers, and natural gas processing plants are potential H<sub>2</sub>S emission sources.

### 2.7.2 Monitoring Network

Currently there are no State or industry H<sub>2</sub>S monitoring sites.

## 2.8 Air Toxics

Air toxics were monitored at Beulah to track air toxics emission at DGC. The data collected was added to the AQS database by ERG.

### 2.8.1 Sources

The major air toxics sources are listed in Table 15 and Figure 15 shows the approximate locations of these facilities (the numbers correspond to the site and source tables).

Table 15

Major Air Toxics Sources  
(>100 TPY)

2003

#	Company	Source	Pollutant Emission	Percentage of Total Emissions	Facility ID
1	Dakota Gasification Co.	Plant	1697	61.58%	3805700013
2	Basin Electric Power Cooperative	Leland Olds Station	318	11.55%	3805700001
3	Northern Sun (Division of ADM)	Oil Seed Processing	220	7.99%	3807300001
4	ADM Processing	Oil Seed Proc. - Velva	181	6.57%	3804900005
5	American Crystal Sugar	Hillsboro Plant	116	4.20%	3809700019
6	Great River Energy - CCS	Coal Creek Station	113	4.11%	3805500017
7	Tesoro Refining and Marketing Company	Tesoro Mandan Refinery	110	3.99%	3805900003

### 2.8.2 Monitoring Network

The air toxics network consisted of one site at Beulah - N. The data collected was reviewed and the contractor added the data to the AQS database. Methyl ethyl ketone (MEK) is the only air toxic that produced any results that were of any interest. Based on data provided by DGC, there seems to be a source of MEK other than DGC though it is not clear what that source could be. The expected concentrations based on DGC-provided data are non-detectable (ND). However, typical concentrations are 1-4 ppm with peaks as high as 1169.2 ppm. Since the data is a 24-hour sample, using wind direction to identify the source has been unsuccessful. Several possible sources have been investigated. These sources are the sampler itself, the construction material in the shelter, and the sample train. The conclusion is that the source is an external source we have not been able to identify. The other data, when compared to other sites of similar industrial influence, are comparable to the other sites monitoring at the same time.

Monitoring was terminated in July when the contracted number of samples was completed. To date the 2003 data has not yet been entered into AQS by ERG.

Figure 15 Major Air Toxics Sources

Data summaries are not included in this review because there are approximately 70 parameters reported. The data is available in AQS using Parameter Occurrence Code (POC) 5.

### 3.0 SUMMARY AND CONCLUSIONS

The North Dakota Ambient Air Quality Monitoring Network is designed to monitor those air pollutants which demonstrate the greatest potential for deteriorating the air quality of North Dakota. Due to a greater number of pollution producing sources in the western part of the State (primarily associated with the energy producing industries) the greatest percentage of the network is located in the western part of the State.

#### 3.1 Sulfur Dioxide (SO<sub>2</sub>)

Neither the State nor Federal standards were not exceeded at any monitoring site. The maximum concentrations and the maximum concentrations expressed as a percentage of the applicable standard are as follows: 1-hour - 157 ppb (57.1%); 3-hour - 120 ppb (24.0%); 24-hour - 51 ppb (51.5%); annual - 5.8 ppb (25.2%).

There is no SO<sub>2</sub> 5-minute standard currently in effect. The maximum 5-minute average was 385 ppb.

#### 3.2 Nitrogen Dioxide (NO<sub>2</sub>)

Neither the State nor Federal standards were exceeded at any of the monitoring sites. The maximum concentrations and the maximum concentrations expressed as a percentage of the applicable standard are as follows: annual - 6.3 ppb (11.89%)

#### 3.3 Ozone (O<sub>3</sub>)

Neither the State nor Federal standard was exceeded during the year. The 1-hour maximum and highest 4<sup>th</sup> highest 8-hour concentrations and the concentrations expressed as a percentage of the applicable standard are as follows: 1-hour - 83 ppb (69.2%); highest 4<sup>th</sup> highest 8-hour - 71 ppb (88.75%).

### 3.4 Inhalable Particulates

Neither the State nor Federal PM<sub>10</sub> standards were exceeded during the year. The maximum concentrations and the maximum concentrations expressed as a percentage of the applicable PM<sub>10</sub> standard are as follows: 24-hour - 79 µg/m<sup>3</sup> (52.7%); annual - 19.8 µg/m<sup>3</sup> (39.6%).

The Federal PM<sub>2.5</sub> standards were not exceeded during the year. The maximum concentrations and maximum concentrations expressed as a percentage of the standard are as follows: 24-hour FRM - 31.0 µg/m<sup>3</sup> (47.7%); annual FRM - 7.6 µg/m<sup>3</sup> (52.7%).

### 3.5 Carbon Monoxide (CO)

No monitoring was conducted.

### 3.6 Lead

No monitoring was conducted.

### 3.7 Hydrogen Sulfide

No monitoring was conducted.

### 3.8 Air Toxics

Data at Beulah is similar to comparable sites operating at the same time. The data and data summaries are available on the AQS database.
