The second pilot program was in the Reuter power station in Berlin. The author was involved in a pilot plant that included a wet scrubber and a TESCR. The result was that it is impossible to have saturated flue gas going to the GGH of the TESCR without drying and pre heating it. The gypsum in the flue gas plugged the TESCR GGH with no means to clean it. The temperatures are too high to clean it with liquid water as it is frequently done on the FGD GGHs.

Utilities built TESCRs in Germany to avoid the arsenic problems. Everybody thought that an indefinite catalyst lifetime could be expected. It was even more surprising to see that the first layer on which activity was measured lost more than 50 % activity in less than 2,000 hours. Again, a new catalyst poison was detected. It was SiF_4, a gaseous component which forms on the plates of the FGD rotary heat exchanger in a reaction of SiO_2, H_2SO_4 and HF. It was an R&D project of several million dollars to detect the poison, the formation mechanism and the solution. Lime was injected upstream of the FGD, which bound the sulfuric acid on the GGH plates. The capital cost of the lime system is certainly not included in the EPRI cost reports referenced by Mr. Hartenstein.

See:

German Experience Sheds Light on SCR O&M Issues, September 1992 issue of Power magazine, Coauthor. (attached).

The author also participated in a more recent pilot test program for a Southeast U.S. Utility. At this particular plant, a proposed SCR system had to be designed for three very different fuels: Eastern bituminous, Venezuelan coal and pet coke. Due to very stringent permit conditions related to NOx, NH_3 and SO_3 emissions, the SCR system and catalyst had to account for the influences of the fuel on the NOx activity and SO_2 oxidation rates of the catalyst. With limited worldwide experience on such a range of fuels, the Utility decided to conduct an extensive pilot program to assess impacts on the catalyst. All three suppliers changed their guarantees after a 2,000 hour pilot test identified significant effects of the various fuels on the expected performance of the catalyst. This SCR is not yet operational.

The EPA also fails to recognize and acknowledge that significant pilot testing has been conducted at two power plants in Texas that fire lignite supplied from various locations in Texas, and that there are no cyclone-fired boilers in Texas. The EPA has gone down the same path that tried to compare German SCR applications, which lack significant cyclone boiler experience and is not currently required for lignite-fired boilers, to be appropriate and comparable to North Dakota lignite-fired cyclone burner units. These are misleading statements and contrary to the presentation of the body of information submitted in support of the NDDH's preliminary BACT determination for MRYS.

These examples emphasize the importance of understanding the intricate process design issues that will influence SCR performance. The industry has benefitted from the many pilot test programs that have been conducted to implement SCR technology when new and unknown process issues have been raised. In the case of Milton R Young, the uncertainty associated with the high sodium concentration and the presence of sodium aerosols in the flue gas raise questions pertaining to catalyst performance. Pilot testing is certainly warranted.

Mr. Hartenstein and his co-authors support pilot programs for those SCR applications in which new and uncertain process considerations are encountered. On page 2 of the technical paper, "Utility Experience with SCR in Germany," presented at the Sixteenth Annual International Pittsburgh Coal Conference in October, 1999, Mr. Hartenstein states: *"In principle, the reduction of NOx emissions with SCR catalysts is a mature technology, which was developed many years ago. Nevertheless, experience has shown that in many applications, special features were required that necessitate further optimization of the DeNOx system. In particular, standard solutions were often not possible or optimal when retrofitting existing power plants."*

Mr. Hartenstein implies, on page A-36 of his report, that catalyst that has been poisoned by sodium compounds can be regenerated in-situ, and that this technique is well developed. Regarding the contention of Hartenstein, there is extremely limited experience with in-situ catalyst cleaning on coal-fired units. ENBW in Germany developed this technique, but it has never had a commercial success. It also has never been used for blinded or chemically poisoned catalyst, but only for mechanically plugged catalyst.

The possible application of any SCR technology at Milton R. Young is not standard, due to the special considerations pertaining to the lignite, boiler operating temperatures, flue gas reheating, among others.

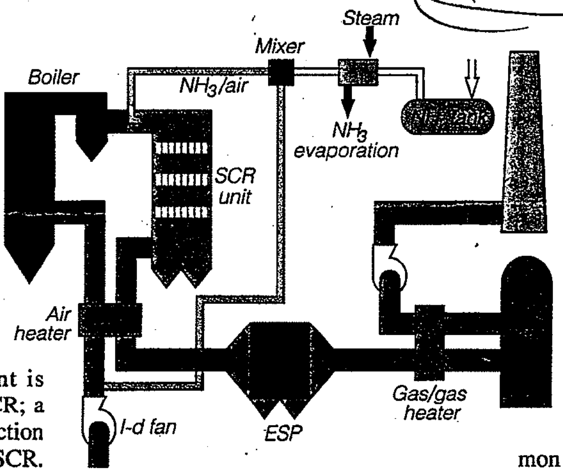
Experience sheds light on SCR O&M issues

German application of selective catalytic reduction (SCR) for controlling NO_x from coal-fired boilers is extensive. But while design of SCR units is well-known, operating and maintenance experience highlights critical issues that may not be understood by US power producers

By **Volker Rummenhohl** and **Helmut Weiler,** Steag AG, and **William Ellison,** Ellison Consultants



1. High-dust systems are located between the economizer and the air heater

Whether prompted by federal, state, or local regulations, it seems clear that new coal-fired powerplants built in the US will require high-efficiency NO_x control. SCR is perhaps the most widely applied technique worldwide for this purpose (POWER special reports, "Controlling NO_x emissions," September 1988; "Clean Air Act Amendments: The Engineering Response," June 1991). One non-utility generating (NUG) plant is being built in New Jersey with an SCR; a utility coal-fired boiler under construction in Florida provides space for a future SCR.

In Germany, SCR has been widely applied to coal-fired boilers. Thus, it is important to transfer the operation and maintenance (O&M) experience from Germany to future US installations.

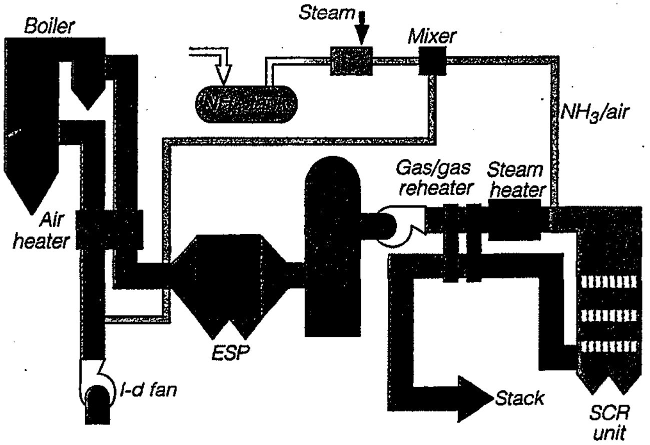
Steag AG has extensive experience with SCR (table) in a wide array of configurations, including boilers fired by ballast coal with sulfur content similar to US bituminous coals.

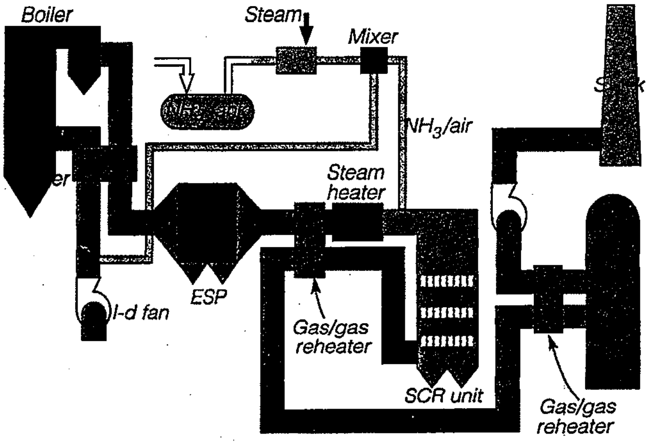
Background

In the early 1980s, the NO_x emissions limit for large coal-fired boilers was reduced to around 100 ppm. To prepare to meet the new stringent standard, Steag AG began pilot-testing SCR in the mid-1980s. Catalysts for SCR had been pioneered commercially in Japan. However, the characteristics of German powerplants were significantly different, including:

- German plants burn a wide variety of low-rank domestic coals with a high content of inerts and impurities; Japanese power stations typically burn high-quality imported coals.
- Slagging-type boilers are common in Germany, but not in Japan.
- At least 90% NO_x removal was the objective for many German plants while Japan utilities had to accomplish 80%.

All conventional pulverized-coal-fired (p-c) units in Steag's system are equipped with so-called "high-dust" SCR configurations (Fig 1), referring to placement of the SCR reactor ahead of the air heater.





For all but one slag-tap unit, the SCR unit is located in a tail-end arrangement (Fig 2), or after the flue-gas desulfurization (FGD) system. In this case, a gas-to-gas flue-gas reheater and a steam-fed heater are located between the FGD and SCR units. The steam-fed heater is used to regulate the temperature of the flue gas entering the SCR unit. This also helps optimize the reduction of NO_x emissions during startup.

Unit 7 at the Walsum station, a slag-tap unit, includes the SCR reactor after the electrostatic precipitator (ESP) but ahead of the FGD system. This is referred to as the "low-dust" configuration (Fig 3).

High-dust units

Two units, Walsum-9 and Herne-4, burn high-ash, medium-to-high-sulfur coal and exhibit high flyash concentrations entering the SCR unit. Plate-type catalysts have proved superior to honeycomb-shaped modules in resisting abrasion and fouling.

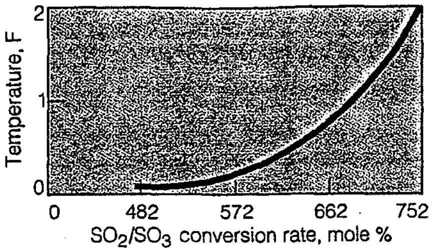
Loss of catalyst activity over time has been considerably less than originally expected for high-dust SCR units. One key factor is the fine lime content of the coal. Here's why: Catalysts also oxidize SO_2 to SO_3. Lime content of the coal neutralizes the sulfuric acid that results from this conversion. If the neutralizing capacity of the coal is not high enough, it is increased by adding limestone or other alkaline compounds to the coal or flue gas.

The first catalyst charge at Walsum-9 had to be upgraded after 27,000 hours of service. Around 25% of the original catalyst capacity had to be added at this point because ammonia slip—that amount that escapes unreacted—caused a disagreeable odor threshold in the flyash and rendered it useless for sale to the construction industry. The original design value of 5 ppm for ammonia slip was too high in Germany.

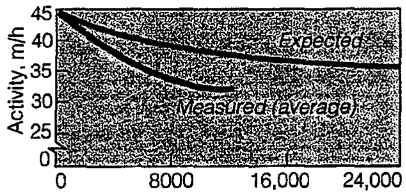
It takes very little ammonia to make ash unsalable. The odor threshold is reached when ammonia content reaches 80 mg/kg of ash—equivalent to 3 ppm, measured at the air-heater inlet, when firing ballast coal or 1.5 ppm when firing high-quality, low-ash coal.

The conversion of SO_2 to SO_3 in SCR systems requires special attention. High SO_3 levels result in corrosion of air heaters, ESPs, and FGD systems as well as the potential for the release of acid aerosols from the stack. Note that wet FGD systems designed for SO_2 removal typically cannot control sulfuric acid aerosol emissions.

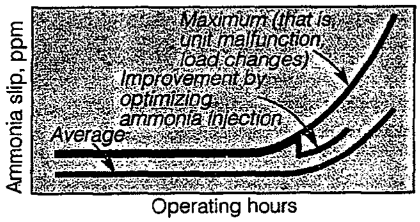
Before SCR retrofit, the German p-c-fired boilers typically operated with flue-gas temperatures at full load ranging between 700 and 715F at the economizer outlet. However, the conversion of SO_2 to SO_3 is temperature dependent (Fig 4). Thus, sootblowing schedules were modified to keep the boilers cleaner and lower flue-gas temperatures to between 660 and 690F. This action reduced SO_3 concentrations at the air-heater inlet from 80 to 40 mg/m^3. This is equivalent to from 22 to 11 ppm. Overall, however, Steag's experience is that high-dust SCR has in some units limited the boiler's operating range.



4. Conversion of SO_2 to SO_3 is highly dependent on temperature



5. Catalyst activity was found to degrade because of poisoning by SiF_4. Lime hydrate injection mitigates the degradation



6. Ammonia slip rises as catalyst ages; optimizing ammonia feed helps stem the increase

Tail-end systems

Experience with the tail-end arrangement was expected to be much better in terms of chemical and physical service life. After all, the flue gas here is low in sulfur compounds and flyash, and materials that can poison the catalyst—arsenic and other heavy metals—are removed by the FGD system upstream. Unfortunately, after only a few thousand operating hours, an extremely high fall off in catalyst activity was observed, particularly on the first layers of honeycomb modules (Fig 5).

The decline in catalyst effectiveness is attributed to the formation of a coating of silicon compounds on catalyst surfaces, generally caused by the presence of silicon fluoride (SiF_4). Sulfuric acid, which condenses onto the FGD flue-gas reheater plates, traps SiF_4 and HF. These compounds combine and later split at the clean gas side into highly corrosive hydrogen fluoride and SiF_4.

Solution to the problem proved to be the injection of lime hydrate downstream of the ESP. This compound reacts with acid gases to form calcium sulfate, calcium fluoride, and other calcium halide compounds. These solids are removed either in the FGD unit or by sootblowing after they deposit on plates in the flue-gas reheater.

Tail-end systems entail high operating expense because of the intermediate steam heating required and the added pressure drop, increasing fan power requirements. On the plus side, they do not limit boiler operation because SCR inlet temperature can be regulated by the steam heater, independent of the boiler.

Monitoring crucial

Regardless of arrangement, monitoring SCR effectiveness must go beyond catalyst activity measurements. At Steag's plants, measurements are taken from sampling systems installed between catalyst layers in addition to recommended measurements taken immediately after the SCR unit. NO_x and NH_3 measurements are taken to detect catalyst degradation early.

Note that both the absolute value of ammonia slip and range of ammonia slip within which the plant can be operated with NO_x compliance rise as the catalyst ages. Constant improvement of ammonia feed regulation has assisted in reducing ammonia slip (Fig 6). ■

Overview of Steag powerplants using SCR

(May 1992 survey)

Station	Output, MW	Furnace type	NO_x in, mg/Nm^3	Config	SCR type	SCR start date	Operating hours

Tackticks, LLC

1.1 General Company Description

Tackticks, LLC has a broad range of engineering experience with SCR systems and related power plant operations. Tackticks, LLC was formed in 2001 by Volker Rummenhohl after working within the SCR industry for almost twenty years, first in Europe then in the US. Tackticks has been involved with SCR's using gas, coal, oil and all types of waste fuel used in boilers, simple cycle and combined cycle systems and incinerators.

The company's primary focus is optimizing process design, catalyst selection and performance of SCR systems on coal-fired boilers. The company's clients are Electric Utilities, Independent Power Producers, Architect & Engineers, OEM's and component suppliers. Tackticks has also been involved in the design of SCR systems, start ups, ammonia injection grid tuning, performance testing, trouble shooting and O & M support.

Tackticks, LLC has special experience with the design, operation and maintenance support of operating units with generation exceeding 15,000 MW. The company's services are targeted to minimize the operating costs of the SCR system, to diagnose operating problems, to enhance overall performance and to assist Clients in managing the most comprehensive catalyst strategies.

The involvement in the SCR strategy contracts enables Tackticks, LLC to be at the front of technology advancement and development.

Tackticks, LLC also currently owns seventy five percent of the flow modeling company FlowTack, LLC. FlowTack, LLC performs CFD and physical flow models for all kind of technologies. Among those technologies is of course also the SCR technology. FlowTack also designs ammonia injection grids for SCR systems.

General Description of Services

The following is a general description of Tackticks' services:

Process Design

Tackticks can assist Clients define the appropriate SCR design parameters. Historical boiler operating data will be reviewed and assessed to determine unit process data at full, mid and low loads. Tackticks can assist Clients in selecting SCR catalyst performance requirements so that the Client's NOx emission control strategy is effectively met with minimum negative impact due to ammonia slip and SO2 oxidation.

Tackticks will help define process distribution requirements so that long term performance and operational demands are met.

SCR Arrangement

Tackticks can assist Clients in determining preliminary SCR arrangements and reviewing initial design criteria. With the use of Computational Fluid Dynamics modeling, Tackticks can recommend optimal arrangements of duct configuration and flow correction devices in order to maintain appropriate flue gas velocities, velocity distribution, fly ash distribution and ammonia to NOx distribution within the SCR system.

Specification Review & Preparation

Tackticks can assist Clients by reviewing turnkey specifications with special attention paid to, but not limited to, design data, guarantees, process design, equipment, catalyst design, potential impacts on boiler and unit operation.

Tackticks can also prepare technical specifications for Clients. Our company focus is generally applied to catalyst selection, ammonia injection grid design, flow modeling and flow correction requirements, reagent system requirements and performance guarantees.

Proposal Evaluation

Tackticks has also evaluated proposals for Clients. The company's assistance in this area can range from a complete technical assessment of a proposed design and its compliance with the specification to an analysis of a specific technical issue. Tackticks will assist in the development of evaluation criteria, preparation of questions to the suppliers, and recommendation of the most qualified supplier.

SCR Troubleshooting and Optimization

Tackticks can assist Operators in solving current operational issues and suggesting improvements to the SCR system in order to enhance overall performance. Services include systems audits, ammonia injection grid tuning, catalyst testing and system inspections.

Requirements for Annual SCR Operation

Tackticks can review SCR operational procedures to ensure appropriateness for annual operation. This includes all operating sub-systems of the SCR system. Tackticks can evaluate seasonal catalyst performance and update for year-round operation. Catalyst management plans can be updated accordingly to coincide with unit outage schedules.

Volker Rummenhohl
247 Booth Meadow Lane
Durham, NC 27713-5810

Work Experience:

FlowTack, LLC
Manager
January 2004 – Present
Mr. Rummenhohl manages FlowTack, LLC a flow model and computational fluid dynamics company.

Tackticks, LLC
President
February 2001 - Present
Mr. Rummenhohl is currently the president of Tackticks, LLC, a consulting firm located in Durham, North Carolina. Tackticks provides process consulting for air quality control systems and specializes in SCR systems. Consulting work includes review of arrangement drawings, writing and reviewing air quality specifications, general process consulting, training, and support during project startup. Mr. Rummenhohl continues to consult with Black & Veatch on the evaluation and design of SCR projects.

STEAG AG
Manager, North America
September 1993 – February 2001

Mr. Rummenhohl was the Manager of STEAG AG's liaison office in Durham, North Carolina. His responsibilities include marketing and implementing the company's experience and expertise in designing, engineering, startup, commissioning, and performance testing of Selective Catalytic Reduction (SCR) systems in North America. During his time in this position, Mr. Rummenhohl has consulted for a number of U.S. utilities, architectural and engineering firms, and manufacturers, conducted seminars, and presented oral and written testimony for regulatory agencies. He was located in the United States to consult with Black & Veatch on the evaluation and design of domestic SCR projects.

STEAG AG
Division Manager, Environmental Engineering Group
January 1990 - August 1993
Duties included the maintenance and continued improvement / optimization of SCR systems for over 5,300 MW of coal fueled electric and cogeneration capacity owned and operated by STEAG. These systems have now been in operation for in excess of 600,000 cumulative hours. Additionally, Mr. Rummenhohl was responsible for the design and engineering of SCR plants. This includes the three SCR plants for the residual oil fired power station Leuna.

Lentjes AG
Project Engineer and Manager
1983 – 1990

Lentjes AG is one of Germany's largest designers, engineers, and constructors of SCR systems. In the position of project engineer and manager, Mr. Rummenhohl was involved in the design, engineering, procurement, construction, and commissioning of over $600 million of SCR systems throughout Germany. Responsibilities included supervision of the startup and commissioning of SCR retrofit systems for 2,200 MW.

University of Dortmund
1981 - 1983

Mr. Rummenhohl is a 1981 graduate engineer with an advanced degree in chemical engineering ("Diplom Ingenieur," comparable to a U.S. Master of Science degree) from the University of Dortmund. After graduation, Mr. Rummenhohl taught as an Assistant Professor for a period of two years at the University.

ROBERT E. JOHNSON

PROFESSIONAL EXPERIENCE

Mar 2007 – Present **Tackticks, LLC – Durham, NC**

Air Pollution Control Consultant -- Specific focus on Selective Catalytic Reduction (SCR) technology and applications. Principal responsibilities include SCR process design analysis and recommendations, Flow Modeling Analysis, SCR performance evaluation, ammonia injection grid design and tuning, SCR system inspections.

2003 – Feb 2007 **Burns & McDonnell Engineers – Kansas City, MO**

SCR Program Manager – Responsible for promoting BMcD's SCR-related activities within the Power Industry. Provided technical consultation on in-house projects to Clients and Project Teams as well as assisting Clients with operating performance evaluations.

Major Accomplishments

- Member of the Team that secured a major SCR design engineering project from a major Midwestern Cooperative.
- Lead technical advisor for ten (10) SCR projects.

1996 – 2003 **C & I Ceramics USA – Alpharetta, GA**
(formerly Siemens Power Generation)

Vice-President, Sales – Responsible for Sales of Siemens' SCR Catalysts to the Power Industry

Major Accomplishments

- Negotiated systemwide agreements with three U.S. Utilities for the supply of SCR catalyst for SIP-related compliance projects.
- Successfully negotiated contracts with other Utilities for similar projects.
- Total Sales in excess of $300 million.

1989 – 1996 **Wahlco Environmental Systems – Leawood, Kansas**

Vice President of New Technologies – Responsible for the commercialization and market development of Wahlco's NOx emission control technology. Coordinated technology assessment and research activities.

Major Accomplishments

- Sold Wahlco's first commercial Staged NOx Reduction System on a gas-fired boiler.
- Negotiated partnerships with key participants in demonstration programs for Staged NOx Reduction System. Instrumental in selecting customers for demonstration sites; successfully negotiated first demonstration on a coal-fired boiler.

- Negotiated first commercial flue gas conditioning installations on a coal-fired cogeneration plant, a hot-side electrostatic precipitator, and the industry's first baghouse application.

1983 – 1989 **Belco Technologies Corporation – Parsippany, New Jersey**

Regional Manager – Directed air pollution control equipment sales for special projects involving new accounts and existing customers with emphasis on flue gas conditioning and microprocessor based control systems.

Major Accomplishments

- Sold Company's first flue gas conditioning system, first precipitator rebuild on a cement kiln, and first new precipitator installation on a cement kiln.
- Sold $2 million of equipment upgrades, control systems and parts.

1983 **Israel Electric Company – Independent Consultant**

1977 – 1982 **Apollo Technologies, Inc. – Regional Manager, Technical Services**

EDUCATION Bachelor of Science, Fairleigh Dickinson University, 1976
Bachelor of Arts, University of Notre Dame, 1975

Attachments: Hans H Response to Tom Bachmann's questions 4-21-09.doc

Hans H
se to Tom Bac

Hi Tom - I have attached a document prepared by Hans Hartenstein responding to your emails of 4/15/09 & 4/16/09 on his informal "Thoughts on the Kling Paper" and accompanying calculations that I originally sent to you on 4/9/09. As you will see, Mr. Hartenstein acknowledges the mathematical errors that you cited and agrees with much of what you stated in your emails. The attached document hopefully clarifies those items that you raised and helps provide some insights on how the Kling and Crespi papers might relate to TESCR at MRYS.

Let me know if you have any questions and thanks for bringing the problems with the previous submittal to our attention.

-Hans

(See attached file: Hans H Response to Tom Bachmann's questions
4-21-09.doc)

Response to Tom Bachmann's questions forwarded to me by Hans Buenning via e-mails dated 4/15/09 and 4/16/09.

In his e-mail dated 4/15/09 Mr. Bachmann stated: *My calculations indicate Center lignite has an average sodium content of over 4,800 ppmd (dry basis) and over 1,600 ppmd of potassium (see attached calculations). This is over 4 times more than Mr. Hartenstein calculated. Of course this is an average and the sodium and potassium can be much higher. These values are higher than for the fuels Kling evaluated based on the sodium and potassium content. In addition, Minnkota is a cyclone boiler versus fluidized bed boilers and PC's. I note this for HDSCR. Of course, for a tail-end SCR the sodium and potassium in the flue gas will be much lower.*

In a follow up e-mail dated 4/16/09 Mr. Bachmann stated: *Just to follow up on my previous email, attached is a corrected version of Mr. Hartenstein's spreadsheet. The corrections are shown in green. He made 2 errors. First, when converting from a wet basis to dry basis he divided by the moisture content instead of one minus the moisture content. Second, when converting from percent Na_2O and K_2O for the Center lignite he was a factor of 10 off. 1.33% K_2O should be 13,300 ppm instead of 1,330 ppm and 4.4% Na_2O should be 44,000 ppm instead of 4,400 ppm. The difference in my calculations is that I converted Na_2O to Na and K_2O to K plus I used 35% moisture instead of 37.13%. I would be interested in any changes to his statements in the "Thoughts on Kling paper" document.*

I acknowledge both errors that Mr. Bachmann identified in my calculations as outlined in his follow up e-mail and agree with his calculations. I also do agree with his statement that the fuels Kling evaluated may have been lower in total sodium and potassium than Center lignite, which, however, would only be relevant for a HDSCR application. In a TESCR application at Minnkota the sodium and potassium containing concentration of particles in the relevant size range of less than 0.1 microns must be expected to be one to two orders of magnitude lower than what Kling exposed the catalyst to in his HDSCR studies. This argument will be supported with data shown below.

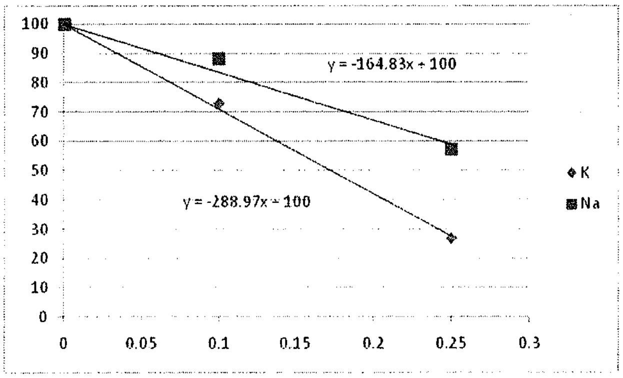
Mr. Bachmann further stated in his initial e-mail dated 4/15/09 that: *Comparison of different flue gases on a ppm/MMBtu basis is, in my opinion, not the best comparison because the amount of flue gas generated by various fuels is different on a MMBTU basis. Most researchers report the deactivation contaminants on a concentration basis (i.e. ppm or mg/Nm^3)).*

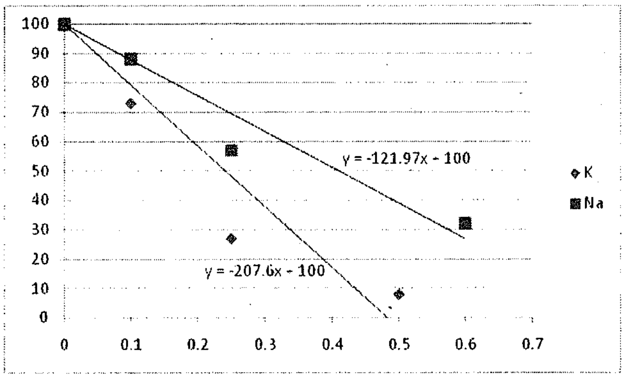
I absolutely agree with this statement and therefore all following comments are based on these units only. Not as an excuse for my error but simply as an explanation as to why I introduced the ppm/MMBtu unit may serve the fact that the Kling paper only reports potassium and sodium concentrations of particles with an aerodynamic diameter of less than 0.1 microns in flue gas concentration units in mg/Nm^3 (Table 5) rather than for all particle sizes. I merely – and certainly incorrectly – tried to quickly calculate some total sodium and potassium concentrations for Center lignite, which, however as we all agree upon, are not really relevant anyway. Mr. Bachmann confirms this by stating in his e-mail dated 4/15/09 that: *In item No. 6, Mr. Hartenstein talks about the form of the sodium and potassium and the effect on deactivation of the SCR. I agree that the form is important. He attributes the ability to inject SBS to control SO_3 to the form of the sodium injected. However, if you review the URS slide presentation, it*

Based on Figure 4 of Crespi, the slopes of the catalyst deactivations due to sodium and potassium up to a V molar ratio of about 0.25 differ by a factor of approximately 1.76. Up to a V molar ratio of about 0.5 the slopes differ by a factor of about 1.70 and past a V molar ratio of 0.5 the slopes flatten out to almost 0 past a V molar ratio of 1. In the following, the determination of these factors will be detailed.

In his e-mail dated 4/16/09 Mr. Bachmann commented: *There is no need to send the Crespi paper as I had requested if Mr. Hartenstein is referring to the paper titled "The influence of biomass burning in the design of an SCR installation". Mr. Hartenstein indicated that potassium is 1.7 times more potent as a catalyst deactivating chemical than sodium based on the Crespi paper. I believe he is referring to Figure 6 in the paper. If so, my interpretation of that figure is only that the molecular weight of potassium is 1.7 times that of sodium (39.1 versus 23.0). The x-axis indicates weight% K equivalent, not potency. The only way you can get a weight percent equivalent is using the molecular weights. If Crespi was trying to indicate a deactivation potency, I believe the formula should be K + Na/1.7; not, K+1.7*Na, since potassium is the more potent chemical.*

Even though Mr. Bachmann's statement concerning the representations on Figure 6 is absolutely correct, I based my statement of Figure 4. Coincidently, the number 1.7 appears in both cases. Extracted from Figure 4 data, the two graphs below show the approximations of the linear deactivations caused by sodium and potassium between V molar ratios of 0 and 0.25 as well as 0 and 0.5 with the equations of the best fit straight lines displayed on the graphs. As can easily be calculated the ratios of the slopes are in both cases approximately 1.7.





Based on this analysis of the data presented by Crespi, I stated that Crespi established a deactivation potency factor between potassium and sodium of approximately 1.7. In other words, potassium is 1.7 times more potent in deactivating catalyst – at least up to a V molar ratio of about 0.5 – than sodium. Therefore, it is correctly represented as 1.7K + Na or K + Na/1.7.

However, the most relevant question is really what is the concentration of sodium and potassium containing particles with an aerodynamic diameter of less than 0.1 microns in case of Minnkota downstream of their scrubber and how do these concentrations compare to the concentrations found by Kling.

don't result in any significant changes of my previous statements concerning the Kling paper and the relevance of its data for this case with respect to the technical feasibility of TESCR for Minnkota's units burning Center lignite.

Table 3 of the Kling paper represents that in the lab standard SCR catalyst deactivated 15% over a period of 1,488 hours in a HDSCR of a PC-fired 400 MW unit burning Uppsala peat + 15% wood, which is a far cry from the 40% claimed in Minnkota's Supplement for Consideration. It also needs to be born in mind that Kling points out that the deactivation of the short catalyst samples tested by Kling in the lab cannot directly be compared with the deactivation of full length catalyst in a full scale SCR reactor. Kling states that since the poisonous components accumulate at the inlet of the catalyst, the catalyst deactivation of the short samples used in the lab will be higher than what would be experienced in a full scale SCR burning the same fuel.

As outlined above, a TESCR after a Center lignite fired Minnkota unit would see even in a absolutely unrealistic worst case scenario a concentration of at least 30 times (more likely 60 – 100 times) less of the relevant combined alkali concentration in particles smaller than 0.1 microns downstream of the scrubber. A factor of 30 would result in an expected catalyst life of at least 45,000 hours. Crespi reports typical TESCR deactivation rates using biofuels at 40% after 50,000 hours – see figure below.

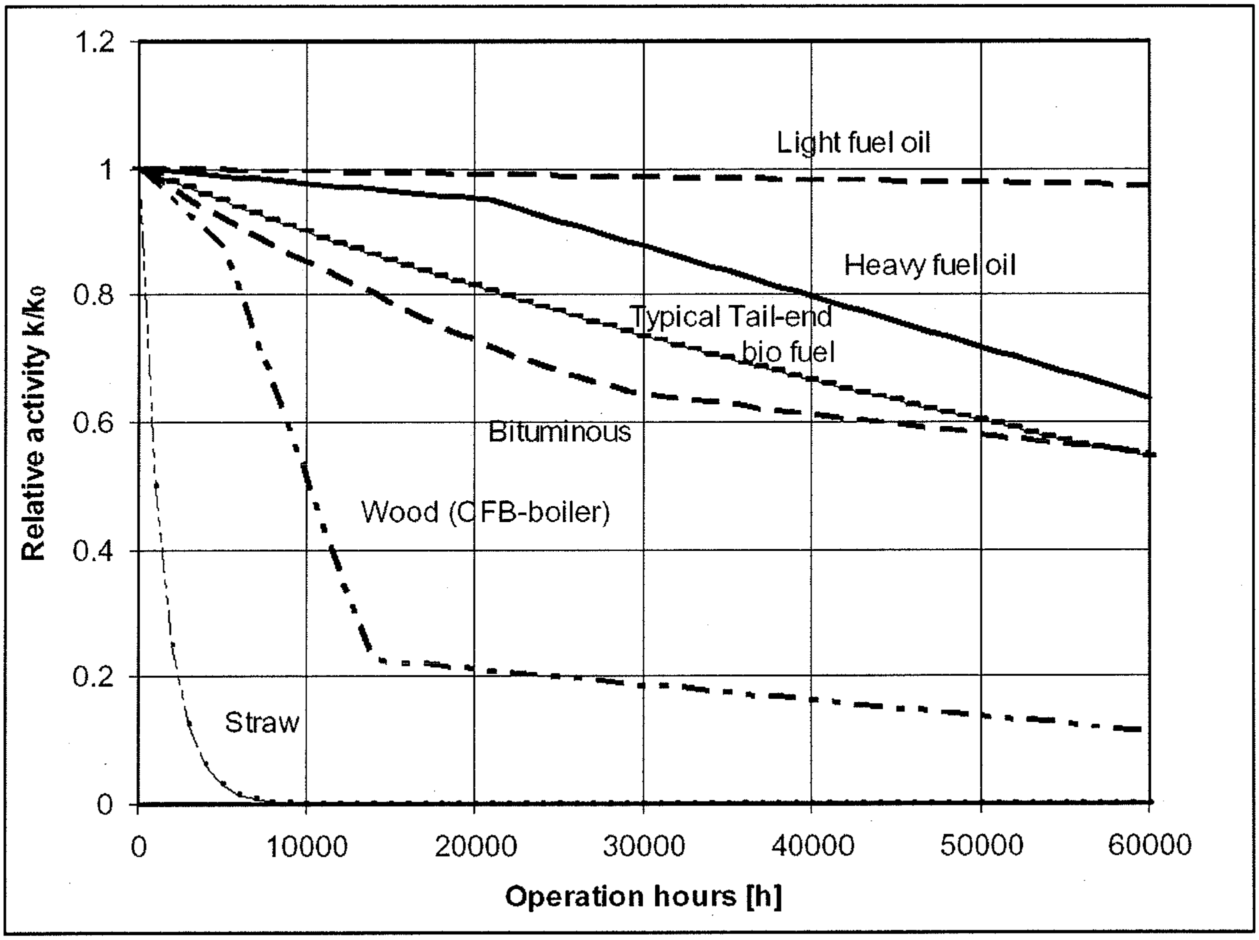


Figure 3: typical catalyst deactivation ratios for different fuel and plant configurations [6]

RE: Supplemental information for the North Dakota Department of Health's Best Available Control Technology Determination for Control of Nitrogen Oxides for M.R. Young Station Units 1 and 2, dated June 2008

Dear Mr. O'Clair:

In response to the Department's request for additional information concerning the use of Low Dust SCRs and Tail End SCRs at Milton R. Young Station, please find enclosed the report titled "Supplemental Information for Consideration Regarding NOx BACT for M.R. Young Units 1 and 2: Technical Feasibility Issues for TESCR or LDSCR Retrofit, February 20, 2009".

Minnkota continues to believe the NDDH's preliminary BACT determination dated June 2008 to be correct and appropriate.

Should you have any questions concerning this submittal, please contact me at 701-795-4221.

Sincerely,

MINNKOTA POWER COOPERATIVE, INC.

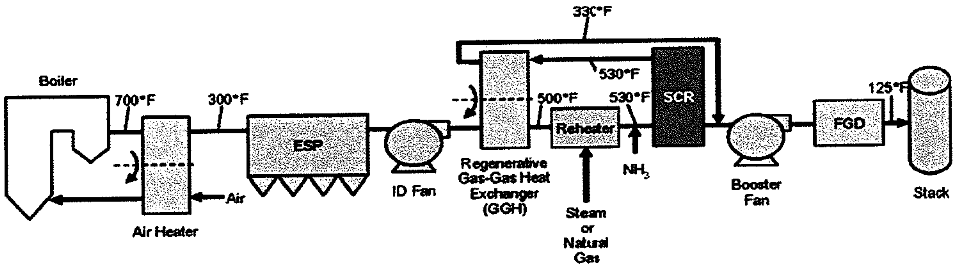
Project No. 31777

Supplemental Information for Consideration Regarding NOx BACT for M.R. Young Units 1 and 2: Technical Feasibility Issues for TESCR or LDSCR Retrofit

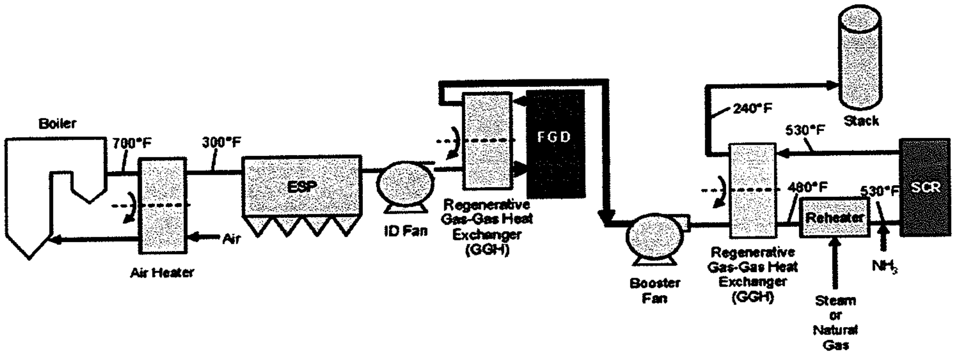
February 20, 2009

1. Purpose

Burns & McDonnell (B&McD), along with Steve Benson of the Department of Chemical Engineering at the University of North Dakota[1], have reviewed the technical literature provided by the North Dakota Department of Health (NDDH) regarding submicron particle collection and penetration for dry electrostatic precipitators (ESPs), and have prepared this document in response. The information and commentary provided herein are being submitted to NDDH for consideration relative to selective catalytic reduction (SCR) technology infeasibility for control of nitrogen oxides emitted from Milton R. Young Station Units 1 and 2. Issues related to the technical infeasibility of SCRs located in both the low-dust configuration (LDSCR) and the tail-end configuration (TESCR) are addressed. [Refer to the basic schematic diagrams below].



Low Dust



Tail End

---

[1] formerly employed by Energy & Environmental Research Center (EERC) of the University of North Dakota.

We continue to believe that the administrative record fully supports a finding by the NDDH that separated over-fire air (SOFA) in conjunction with selective non-catalytic reduction (SNCR) technology is Best Available Control Technology (BACT) for NOx control for electric generating units that utilize cyclone burners firing North Dakota lignite.

2. Scope

The following sections address specific topics pertaining to the NDDH's Preliminary NO_X BACT Determination for Nitrogen Oxides for Milton R. Young Station Units 1 and 2, dated June 2008 (NDDH, 2008)

- Significance of submicron aerosol particle removal by ESPs and wet FGD
- Evaluation of submicron particle penetration data provided by NDDH
- Sodium-rich aerosol formation and penetration through ESP and FGD at M. R. Young Station firing North Dakota lignite
    - Form of sodium in Center lignite
    - Vaporization of sodium in the high temperature cyclones' combustion process
    - Condensation of sodium and concentrating in the submicron size fraction
    - Electrostatic precipitator collection efficiency
    - Aerosol capture efficiency in scrubbers
    - Powerspan testing at MRYS
    - MRYS sulfate aerosol sampling
- Determination of Sodium Loading Adversely Affecting SCR Catalyst Performance
- Alkali Aerosol Loading and Catalyst Deactivation
- Experience of ESP/FGD equipped utility plants co-firing biomass and coal with TESCR
- Relevance of recent TESCR investigations at We Energies' South Oak Creek Station
- Relevance of ongoing LDSCR installation at We Energies' South Oak Creek Station
- Relevance of existing LDSCR installation at PSEG Mercer Station
- Additional technical feasibility issues for TESCR at MRYS
- Summary and Conclusions

3. Significance of Submicron Aerosol Particle Removal by ESPs and Wet FGD

The removal percentage of submicron or aerosol particles by an ESP or any other device is not important. The key is not what is removed, but rather the quantity that is not removed. The amount (mass and number) of submicron and ultrafine particles, as well as the speciation of the particles which pass through the ESP, are extremely important. These particles have the following detrimental characteristics:

- Condensed vapor phase species concentrate in the less than 1 µm size fraction and are in the range of particle sizes where ESPs and wet flue gas desulfurization systems (FGDs) are ineffective in capturing them
- Small particles that can penetrate deep into catalyst pores
- Highly reactive, because of chemistry [rich in sodium (Na), potassium (K), sulfur (S), phosphorus (P)], which results in poisoning sites
- Highly reactive, because of physical characteristics – high surface area can react with gas phase species, which results in blinding of pores
- Highly concentrated because of the removal of larger particles by cyclone and air pollution control devices
- Highly concentrated aerosols (not diluted by large particles) that upon accumulation can efficiently bond together causing catalyst blinding and are available to poison active sites

4. Evaluation of Submicron Particle Penetration Data provided by NDDH

The NDDH provided publications on the efficiency of ESPs and scrubbers to remove particulate as well as penetration of aerosol particles through the devices. The following are some of the key conclusions that can be drawn from the review of the information described in these papers. The information provided indicates poor collection efficiency of submicron particles:

- The particulate collection efficiencies for the coarse fraction particles or particles larger than 1 to 5 µm in ESPs are generally very good (99.9%).

- For particles less than 1 µm, the collection efficiency drops off significantly.
- Particles in the finer size fractions are largely composed of condensed vapor phase species such as sodium, potassium, chlorine (Cl), and sulfur.
- Higher combustion temperatures result in more vaporization and increased levels of submicron particles.
- Emission rates downstream of ESPs described in the reports range from 4,500 to 50,000 µg/Nm^3. The particulate are dominated by aerosols rich in sodium and potassium. NOTE: The level of 22,500 µg/Nm^3 of sodium and potassium rich fly ash derived from biomass resulted in catalyst deactivation of 40 % in 1500 hours (Kling and others, 2007).

Specific observations and/or comments on each of the documents provided by NDDH are presented below:

Mohr, M., Ylatalo, S., Klippel, N., Kauppinen, E.I., Riccious, O., and Burtscher, H., Submicron Fly Ash Penetration through Electrostatic Precipitators at Two Coal Power Plants, Aerosol Science and Technology 24:191-204(1996)

Measurement of the size distribution of fine particulate (diameter less than 0.5µm) at the inlet and outlet of the ESP for two full scale pulverized coal fired power plants was conducted. The coals fired consisted of high volatile bituminous coals from South Africa and Columbia. The characteristics of these coals are summarized in Table 1. The analysis indicates very low levels of sodium as well as other alkali and alkaline earth elements [K, calcium (Ca), and magnesium (Mg)]. The potential for formation of alkali rich aerosols from these coals is extremely small because of the form of the alkali and abundance.

Table 1. Coal analysis (Mohr and others, 1996)

COAL				
Country		South Africa	Colombia	South Africa
Coal field		Klein Kopie	Eldorado	Klein Kopie
Location of burning		Plant A	Plant A	Plant B
Date		9.5.94	17.5.94	11.8.93
Proximate analysis				
Total moisture	%	9.9	13.5	7.4
dry weight bases				
Ash	%	17.1	10.2	16.2
Volatile matter	%	20.7	35.5	23
fixed carbon	%	62.2	54.2	60.9
Gross calorific value	MJ/kg	27.42	29.99	27.34
Ultimate analysis				
Carbon	%	70.3	73.4	68.4
Hydrogen	%	3.4	4.6	1.5
Nitrogen	%	1.7	1.5	3.5
Oxygen	%	7	9.4	9.9
Sulfur	%	0.43	0.81	0.5
Coal ash				
P_2O_5	%	1.2	0.3	1.2
SiO_2	%	45.3	55.7	47.7
Fe_2O_3	%	3.5	7.3	3.1
Al_2O_3	%	31.4	21.0	33.2
TiO_2	%	1.6	0.9	1.7
CaO	%	7.3	4.1	6.2
MgO	%	1.7	2.1	1.4
SO_3	%	5.4	3.1	4.8
K_2O	%	1.0	2.1	0.7
Na_2O	%	0.3	0.6	0.2
Li_2O	%	0.0	0.0	0.0

By comparison, Table 2 summarizes the average lignite properties relevant to MRYS. It can be seen that the characteristics of the MRYS coals are very different and will produce significantly different size distributions of ash than the coals fired in the plants reported by Mohr and others, 1996.

Table 2. Average Center lignite and ash composition (moisture, ash, sulfur, and heating value expressed on an as-received basis; and ash composition expressed as weight percent equivalent oxide of the ash).

	Moisture,%	Ash, %	Sulfur, %	Btu/lb	Al_2O_3	BaO	CaO	Fe_2O_3	MgO	P_2O_5	K_2O	SiO_2	Na_2O	SO_3
Average	37.13	9.64	0.98	6578	11.68	0.52	13.15	8.90	3.99	0.12	1.33	36.04	4.40	18.39

This testing has little relevance to the collection of ash in the MRY boilers for two primary reasons. The first is the firing type. The boilers are pulverized coal (PC)-fired and partitioning to the finer ash fraction will be much lower than that observed for cyclone-fired boilers. The second reason is coal type. The coals tested are bituminous coals. The ash forming components in the bituminous coals are mineral grains with no organically associated elements (Na, K, Ca and Mg). The fraction of the elements in an easily vaporizable form is much lower in the bituminous coals producing lower levels of ash in the smaller sized fractions.

Nobrega, S.W., Falaguasta, M.C.R., and Coury, J.R., A Study of a Wire-Plate Electrostatic Precipitator Operating in the Removal of Poly dispersed Particles, Brazilian Journal of Chemical Engineering, Vol 21, No. 02, pp 273-284, April-June 2004.

This paper is a laboratory and computer modeling effort that examined the performance of ESPs. The precipitators tested were small scale laboratory systems. A phosphatic concentrate was used as particulate. Computational models for predicting fine particle removal in ESPs were improved. However, the relationship to particulate collection from coal fired power systems is small.

Power Station Emissions Handbook, Cooperative Research Centre for Coal in Sustainable Development, http://www.ddsd.biz/PSE_Handbook/5/6/5/index.cfm accessed 11/24/2008.

This document states:

"Wet scrubbers can remove more than 90% for particles with diameters above 10 microns. Efficiencies for smaller particles will be significantly lower."

"The size distribution of the dust influences the overall ESP collection efficiency. Particles in the range of 0.1 to 1.0 µm are the most difficult for an ESP to collect. "

"ESP collection efficiency is particularly affected by several factors including coal ash resistivity, gas temperature, chemical composition and particle size distribution (Wu 2001)."

There is no discussion on fly ash types that are collected. Only general data is provided. Application to high sodium lignite derived coal ashes is not apparent from the website.

ICAC Institute of Clean Air Companies, Particulate controls, http://www.icac.com/i4a/pages/index.cfm?pageid=3398

This website states:

"Precipitator collection efficiencies will be somewhat lower for particles with diameters near 0.3 microns. The reason for a minimum in collection efficiency for 0.3 micron particles is that both particle charge and the resistance of the gas to particle motion both increase with particle size. Near 0.3 micron, the particle charge is low enough and the resistance to particle motion is high enough that particles are collected relatively poorly."

These conclusions indicate that aerosols can penetrate through ESPs.

Lind, T., Hokkinen, J., and Jokiniemi, J.K., Saarikoski,S., and Hillamo, R., Electrostatic Precipitator Collection efficiency and Trace Element Emissions from Co-Combustion of Biomass and Recovered Fuel in Fluidized-bed Combustion, Environmental Science and Technology, 2003, 37, 2842-2846.

This paper describes the removal efficiency of ash particles produced in a 66 megawatt (MW) biomass-fired bubbling bed fluidized bed combustion (FBC) system. Fluidized bed combustion systems operate at lower temperatures (1400 to 1600 °F) than conventional pulverized coal-fired or cyclone-fired utility boilers. The bed material in the FBC was sand. The fuel was mixture of peat and wood wastes. Fluidized bed systems typically have significant levels of entrained ash particles that provide sites for condensation of vaporized species. The particles that penetrated the ESP were found to contain mostly alkali salts (Na, K, Cl, and SO_4). The quantity of materials penetrating the ESP was 4.5 to 9 mg/Nm^3 (4,500 to 9,000 µg/Nm^3).

The 2003 paper by Lind references her earlier work on ash formation mechanisms (Lind, and others, 2000). This paper describes in detail the mechanisms of formation of the aerosol particles and that they are enriched in alkali salts (Na, K).

Ohlstrom, M., Jokiniemi, J., Hokkinen, J., Makkonen, P., and Tissari, J., Combating Particulate Emissions in Energy Generation and Industry, Tekes, VTT Technical Research Centre of Finland, 2006.

This paper also describes the concentrating of vaporized elements such as sodium and potassium in the fine (less than 1 µm) size fraction. The authors also state "higher combustion temperatures typically increase the amount of fine particle released." In addition, they discuss the fact that "Electrostatic precipitators are at their least efficient when handling particle sizes between 0.1 µm to 1 µm." They indicated in Table 8 on pg 29 of the report that the emission rates ranged from 15 to 50 mg/Nm^3 (15,000 to 50,000 µg/Nm^3) from the ESP. This paper also shows that scrubbers are extremely ineffective in removing aerosols.

5. Sodium-Rich Aerosol Formation and Penetration Through ESP and FGD at M. R. Young Station Firing North Dakota Lignite

As described above, the fly ash penetration derived from the preceding described literature is not fully relevant to MRYS due to the significant differences in the sodium content of the fuels fired and the differences in the fuel firing mechanism employed in the plants tested. The following discussion will briefly review the following topics:

- Form of sodium in Center lignite
- Vaporization of sodium in the high temperature cyclones' combustion process
- Condensation of sodium and concentrating in the submicron size fraction
- Electrostatic precipitator collection efficiency for fine particulate and relationship to ash produced from Center lignite
- Aerosol capture efficiency in scrubbers
- Powerspan testing at MRYS
- MRYS sulfate aerosol sampling.

Form of Sodium in Center Lignite

Sodium is associated with the organic matrix in Center lignite. That means the sodium is atomically dispersed in the organic matrix. The sodium is associated with a carboxylic acid groups (ion exchange sites). The carboxylic acid groups act as bonding sites for various elements such as Ba, Ca, Mg, and Sr along with minor amounts of K. Figure 1 illustrates the bonding of sodium to the organic fraction of the coal and the association of other coal impurities.

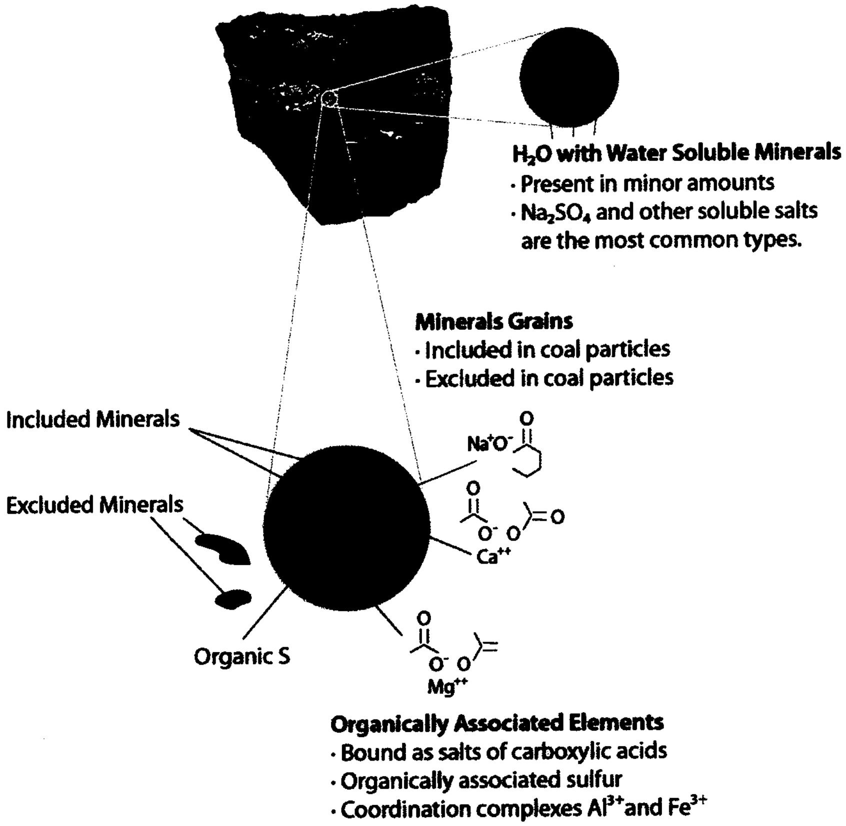


Figure 1. Form of sodium in coal (Benson and Laumb, 2008).

Vaporization of Sodium in the High Temperature Cyclones' Combustion Process

Sodium is a volatile element and is in the easily volatilized organic form in Center lignite and will be transformed into a gas upon combustion. The vaporization of sodium during the combustion of lignite is a very well known fact that has been examined by numerous investigators, including work conducted by MIT, CalTech, Sandia National Laboratory, National Energy Technology Laboratory, University of Utah, and others (see review by Lighty and others, 2000). For example, research conducted by Senior and others (2000) reported that relative to other coals, North Dakota lignite produced more vaporized ash. The actual amount vaporized for ND lignite is double the level vaporized as compared to subbituminous and lignite coals from Montana as illustrated in Figure 2.

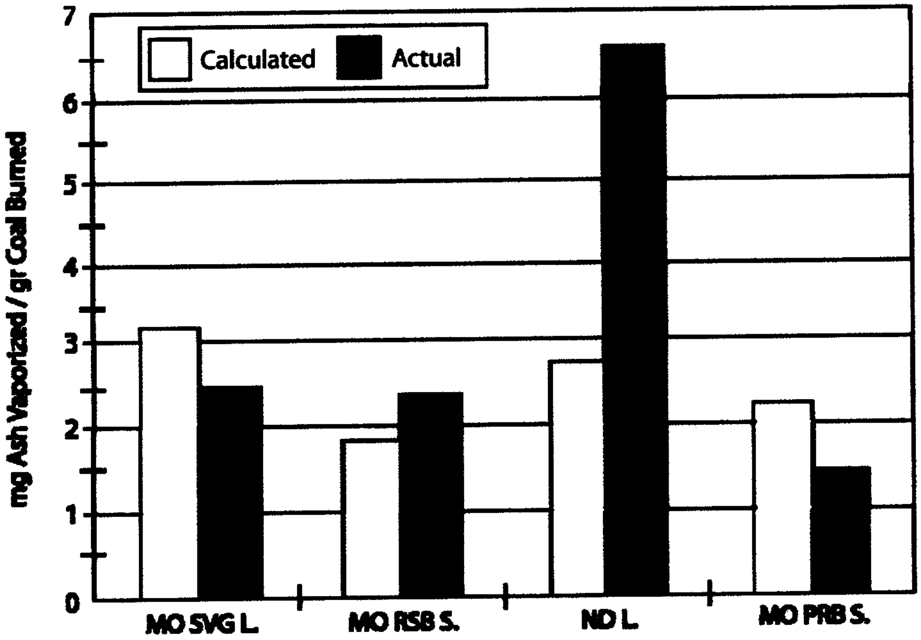

Figure 2. Ash vaporized during combustion of lignite and subbituminous coals (Senior and others, 2000).

Work conducted at the MRY plant related to the vaporization of sodium from a cyclone fired system is illustrated in Figure 3. The results show over two thirds of the sodium is not retained in the slag and is vaporized in the high sodium lower ash coals 1-3. In the low sodium high ash coals 4-5, very small amounts of the sodium was vaporized.

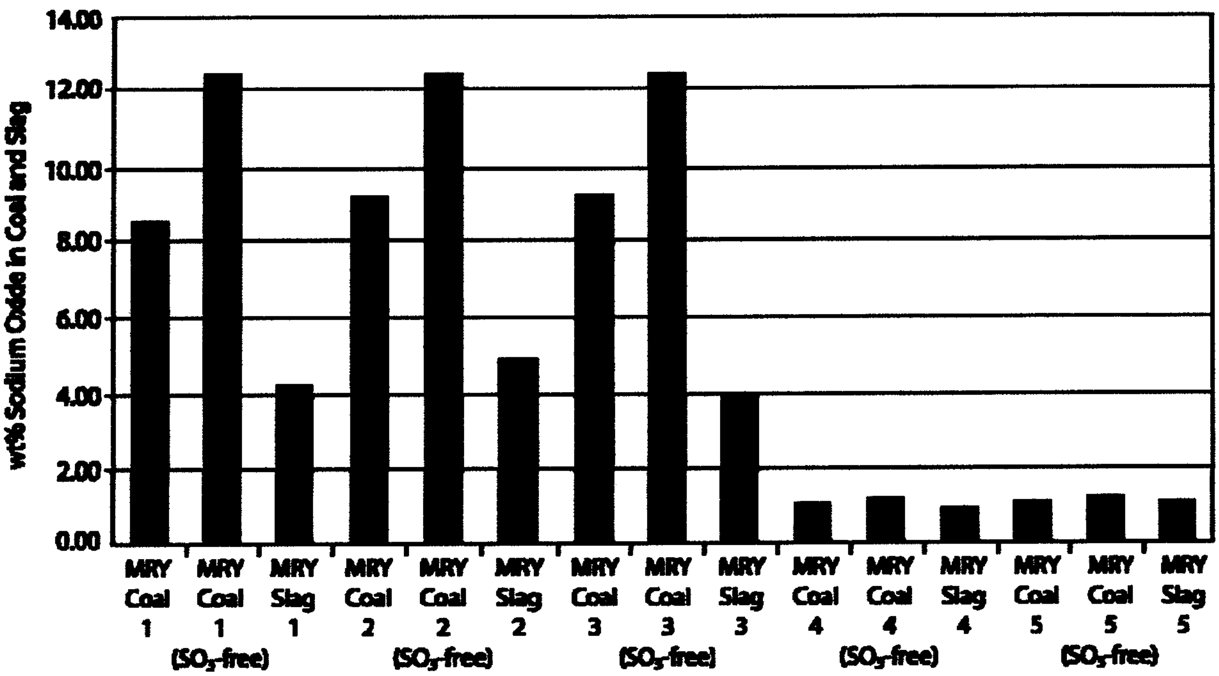

Figure 3. Comparison of sodium levels in Center lignite coal and slag samples.

Condensation of Sodium and Concentrating in the Submicron Size Fraction

EPA has evaluated the literature on particle formation during combustion and from other sources and incorporated it into an educational module that was found on the following website: (http://www.epa.gov/apti/bces/module3/formation/formate.htm). The classification of particle types shown by EPA is illustrated in Figure 4. The EPA classification is consistent with the review conducted by Lighty and others (2000). Vaporized species can condense heterogeneously on surfaces of other entrained coarse ash particles and can condense homogeneously to form the fine and ultrafine particles. The distribution of particles depicted in Figure 4 is shown on a "frequency percent particles by mass" basis. The number of particles versus size is also important. A comparison of the number of particles and particle size is summarized in Table 3. The number of aerosol particles is significant. These particles have high surface areas and are very reactive.

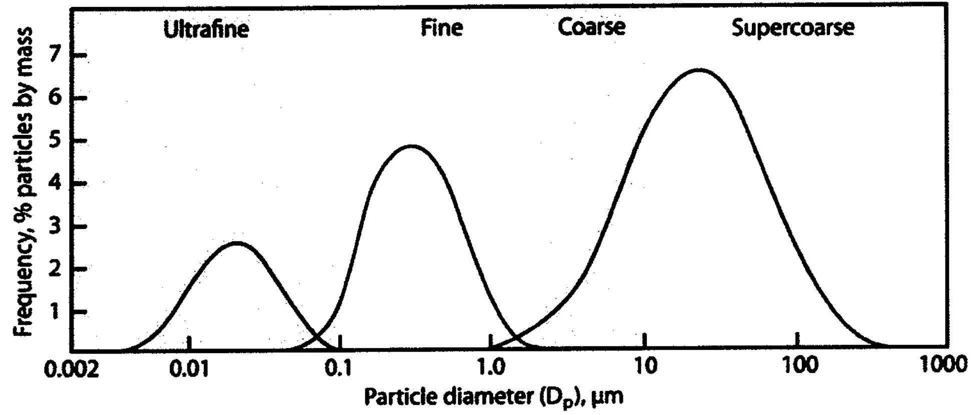

Figure 4. Particle size categories used to classify particles.
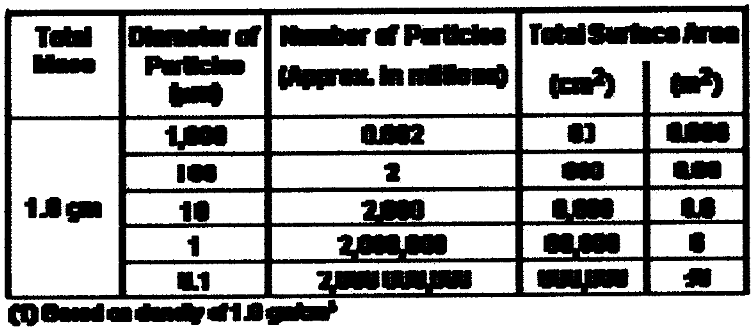
(http://www.epa.gov/apti/bces/module3/category/category.htm)

Figure 5 provides a comparison of the mass distribution and particle number distribution. As the particle size decreases the number of particles in the size fraction increases. In addition, as illustrated in Table 3, the surface area increases significantly with decreasing particle resulting in the opportunity for reactive gases such as sulfur oxides to react, forming sticky phases that bond particles together.

Table 3. Particle size, number of particles, and surface area[1]
(http://www.epa.gov/apti/bces/module3/category/category.htm)



Total Mass	Diameter of Particles (µm)	Number of Particles (Approx. in millions)	Total Surface Area (cm²)	(m²)
1.0 gm	1,000	0.002	60	0.006
	100	2	600	0.06
	10	2,000	6,000	0.6
	1	2,000,000	60,000	6
	0.1	2,000,000,000	600,000	60

(1) Based on density of 1.0 g/cm³

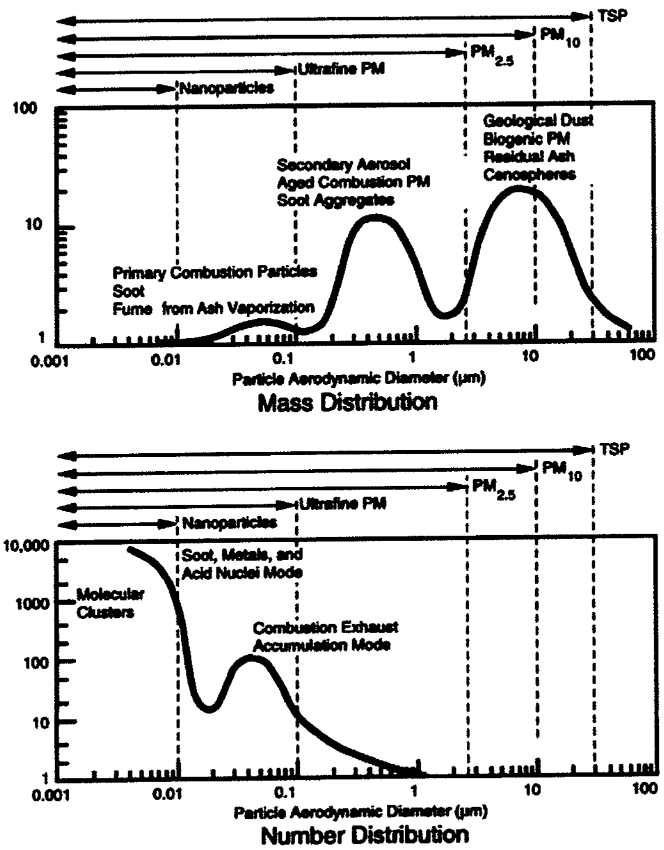


Figure 5. Comparison of Mass Distribution and Particle Number Distribution for Combustion Derived Particles and Aerosols (Lighty and others, 2000).

Particle size distributions for fly ash collected upstream and downstream of an ESP are illustrated in Figure 6. This work was conducted by Markowski and others (1980) specifically aimed at characterizing the submicron aerosol mode of fly ash formation. Figure 6B shows the penetration of fine particulate through the ESP.

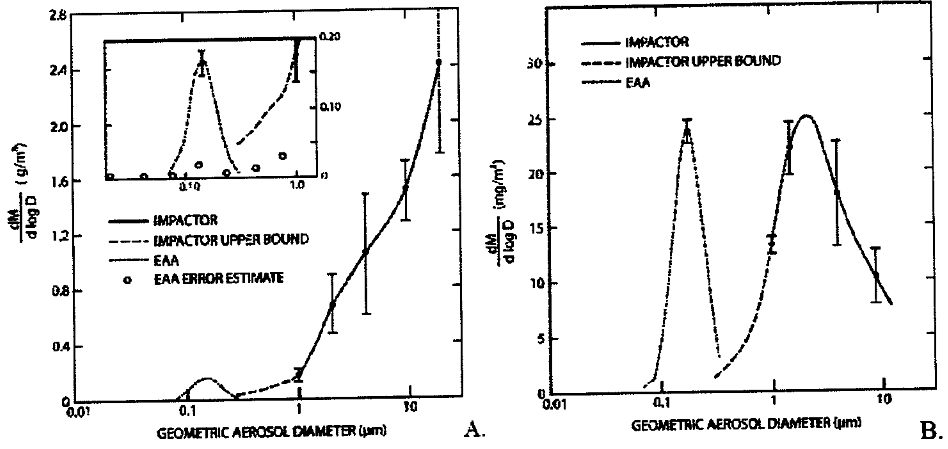

Figure 6. Typical differential mass distributions of particulate collected upstream (A) and downstream of an ESP (b) (Markowski and others, 1980).

Fly ash produced upon the combustion of high sodium lignites in a pulverized coal (PC) fired system shows significant enrichment of sodium in the smaller size fractions as shown in Figure 7. This figure illustrates the increase in the sodium content in the finer size fractions of ash as a result of firing high sodium lignite. The sodium and sulfur content of the less that 3 micrometer size fraction of the sampling train approached 20% Na_2O, and 25% SO_3. The form of the sodium is likely sodium oxide and sulfate.

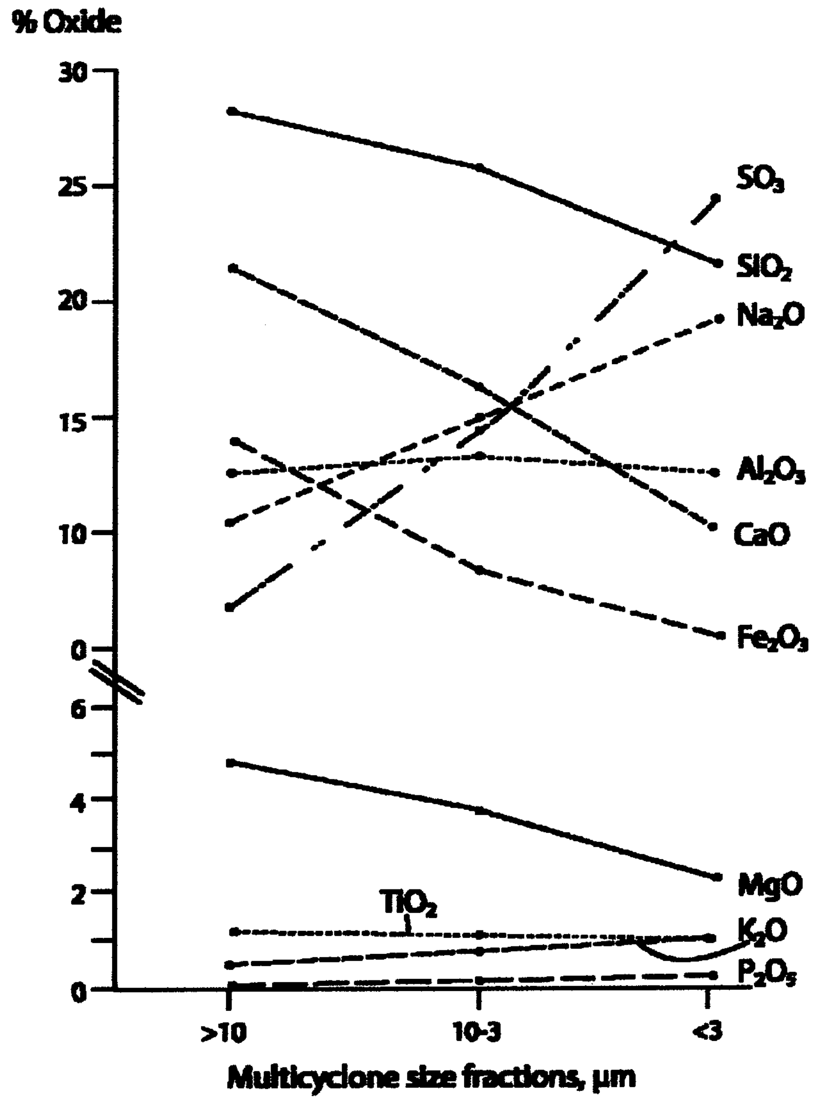

Figure 7. Composition distribution of ash particles during combustion of North Dakota Lignite (Benson and others, 1984).

Electrostatic Precipitator Collection Efficiency

The classical curve for ESP particle collection efficiency is shown in Figure 8. This curve is typical of well behaved ash materials that do not present significant problems in collection. The collection efficiency is very good for particles greater than 5 to 10µm and the collection efficiency decreases with decreasing particle size, with a minimum collection efficiency between

0.2 to 2 µm in diameter. The collection efficiencies vary significantly because of particle size and composition.

Low collection efficiency for difficult to collect particles is between 0.1 to 1 µm in particle diameter. Figure 9 provides an illustration of the range of collection efficiencies. Based on EPA education modules (http://www.epa.gov/apti/bces/module3/collect/collect.htm), no air pollution control device shows high collection efficiency in this range (0.1 to 1.0 µm) due to inherent limitations of the collection devices and particle characteristics. The following mechanisms of particle capture are impacted by the size of the particles. The impact of these mechanisms are described

- Inertial impaction and interception
- Brownian diffusion
- Gravitational settling
- Electrostatic attraction
- Thermophoresis
- Diffusiophoresis

The EPA has indicated that based on a number of studies of actual "sources stationary sources generating high concentrations of particles in the 0.1 to 0.5 micrometer range may be an especially challenging control problem. ... The gap is most noticeable in wet scrubbers and electrostatic precipitators." A generalized plot showing the range of collection efficiencies is shown in Figure 9. Overlaid on the diagram is the mass size distribution of particles collected downstream of the ESP wet FGD at the MRY plant (Markowski and others, 1983). This shows that ash produced in the MRY plant have a particle size that pass through the scrubber and that these particles are rich in sodium as previously shown in Figure 7.

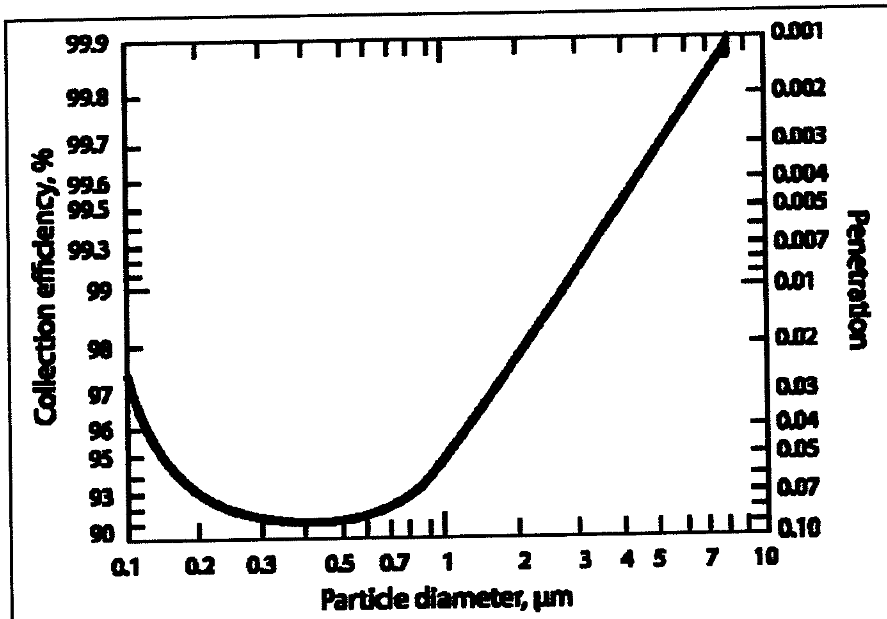

Figure 8. Typical ESP Collection efficiency curve for removal of particulate from gas streams (http://www.epa.gov/apti/bces/module3/collect/collect.htm).

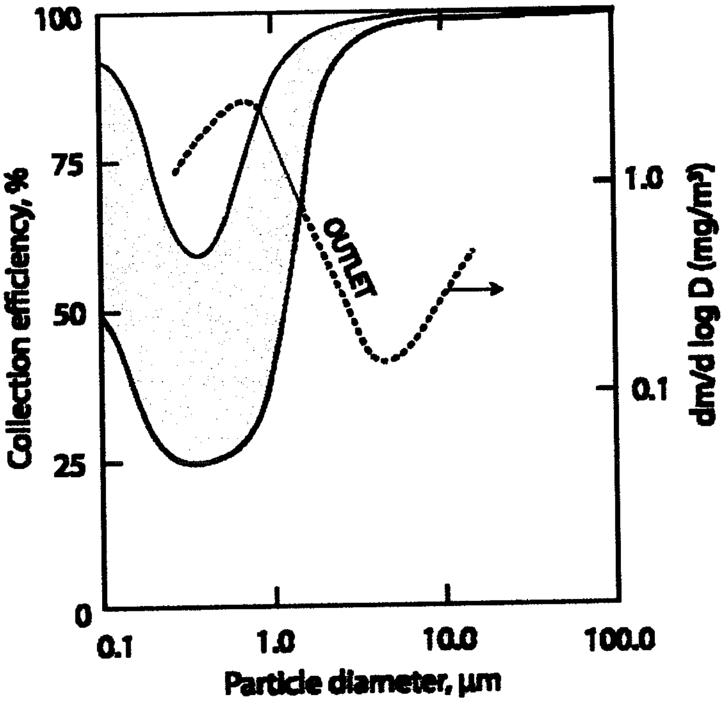

Figure 9. Particulate control efficiency for difficult to control particulate combined with the mass distribution of particulate collected downstream of the scrubber at MRYS (Markowski and others, 1983 and (http://www.epa.gov/apti/bces/module3/collect/collect.htm).

Aerosol Capture Efficiency in Scrubbers

As indicated by EPA (Woodward, 1998), scrubbers do not effectively remove particulate less than 1 µm in diameter. There is significant evidence that sodium-rich aerosols penetrate ESPs as well as scrubbers at full-scale power plants when firing high-alkali-containing fuels. An example is a biomass fired system using a tower type scrubber where the removal efficiency of the smaller size fraction of ash is low, as shown in Figure 10 (Ohlström and others, 2006).

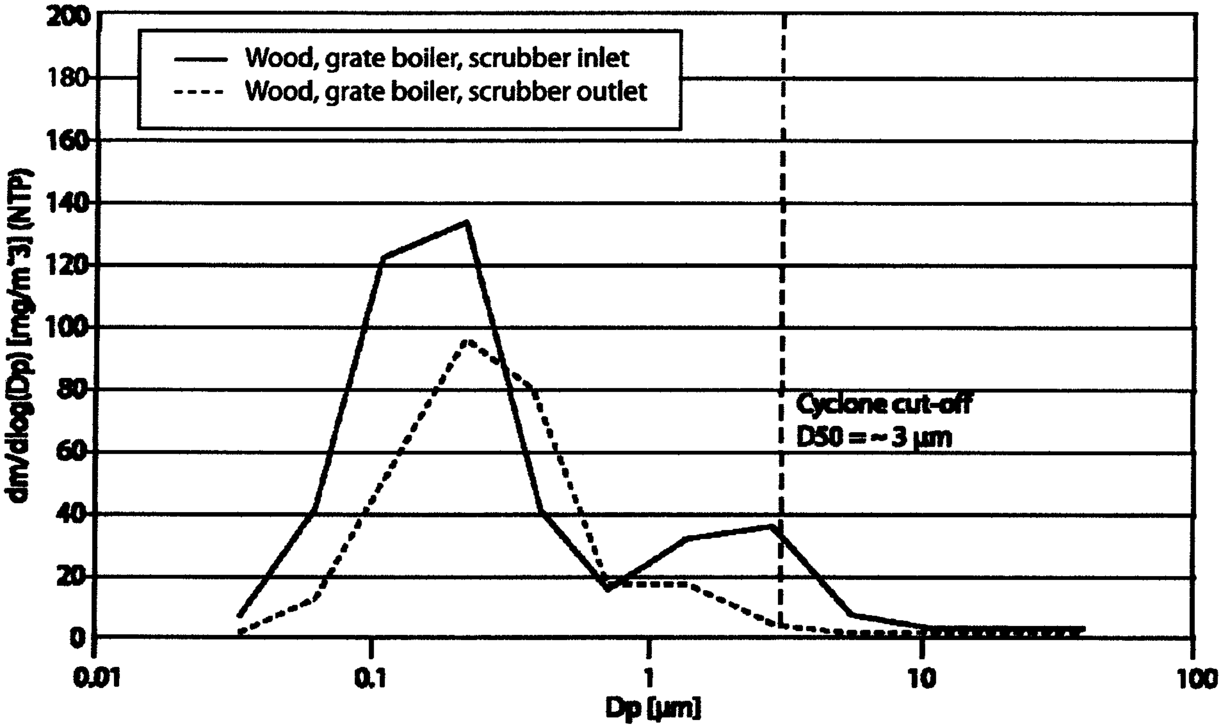

Figure 10. Removal of fine aerosols using a scrubber on a wood fired combustor (Ohlström and others, 2006).

Minnesota Power's Boswell Energy Station found that when it fired high-sodium, lower-ash northern Powder River Basin subbituminous coal (7% Na_2O in the ash), it experienced increases in opacity. Hurley and Katrinak (1992) conducted a field-testing project on Unit No. 4, a pulverized coal-fired boiler equipped with a venturi wet scrubber, to better understand the reasons for the opacity problems. During the field testing, sampling of the coals, flue gases, and scrubber materials was conducted. The particulate in flue gases downstream of the scrubber was aerodynamically classified using multicyclone followed by an impactor and a Nucleopore filter.

The sized fractions were weighed and analyzed to determine the abundance and composition of the submicron-sized fractions. The mass loadings in the various size bins are plotted in Figure 11, showing that the scrubber is quite effective in removing the larger particles. However, the scrubber is not very effective in removing the aerosols less than 1 micrometer in diameter for both the blended coal and the high sodium coal (Coal A).

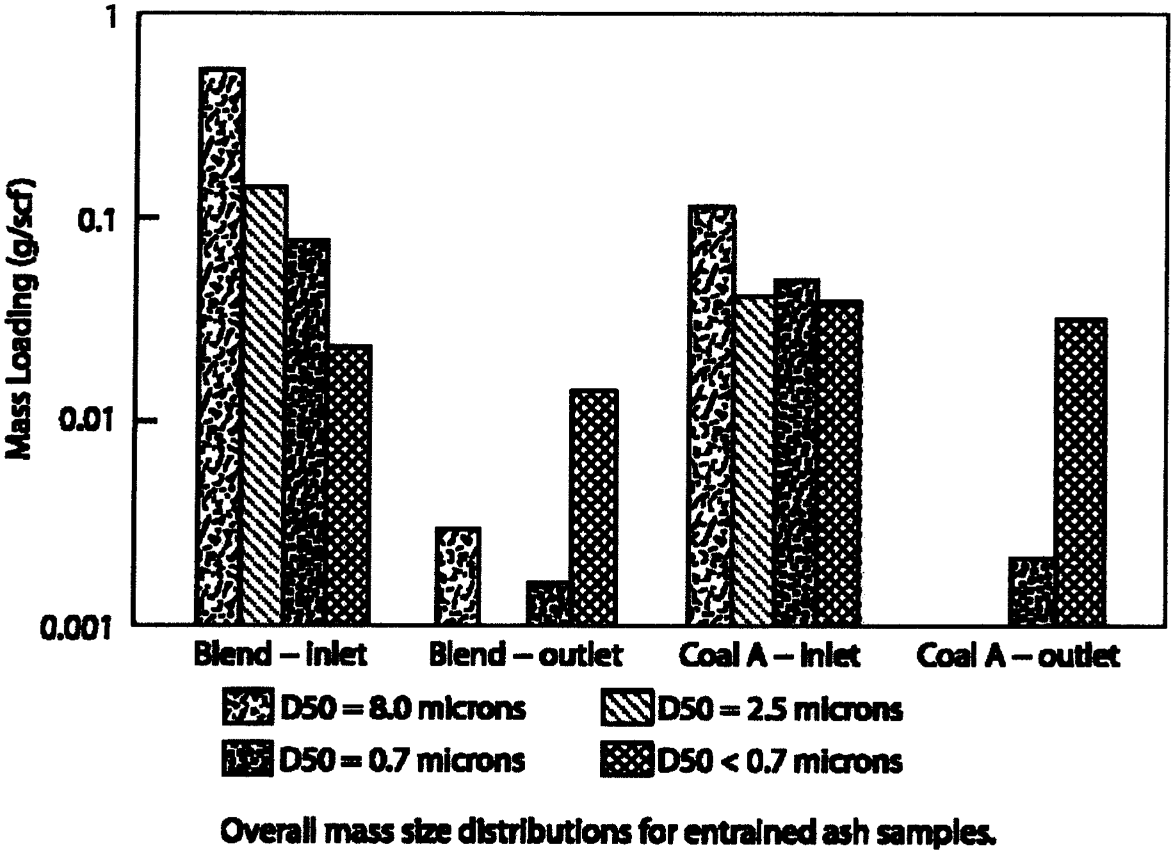

Figure 11. Mass loadings and size for particulate collected upstream and downstream of the wet venturi scrubber at Clay Boswell plant (Hurley and Katrinak, 1992)

The results of the study indicated that the particulate collected downstream of the scrubber was coal-related and caused by the high sodium content of the coals. Vapor-phase sodium condenses in the boiler's convective pass to form fine sodium-rich aerosols or other Na species that later react with ash particles. Pure Na_2SO_4 particles are too small to be removed by such scrubbing. Figure 12 shows the spikes of the ash material collected on Stage 10 of the impactor. This impactor accumulation represents particles of less than 0.7 to 2.5 micrometer size fraction of the submicron aerosol. The spikes are made up of submicron particulate matter, and the chemical analyses of the spikes and ash particles collected on the Nucleopore filters downstream of the impactor plates are shown in Table 4. Both samples are dominated by sodium and sulfur that are likely in the form of sodium sulfate. These sulfate materials exhibit highly cohesive tendencies.

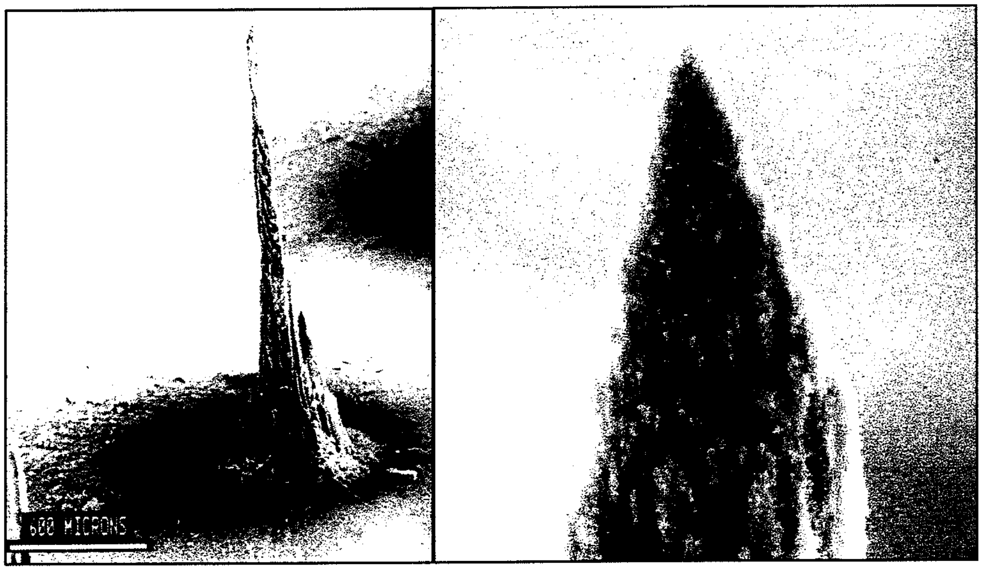

Figure 12. Scanning electron microscope images of spikes formed on impactor plates when high-sodium subbituminous coal is combusted (the picture on the right is a close-up of the spike) (Hurley and Katrinak, 1992).

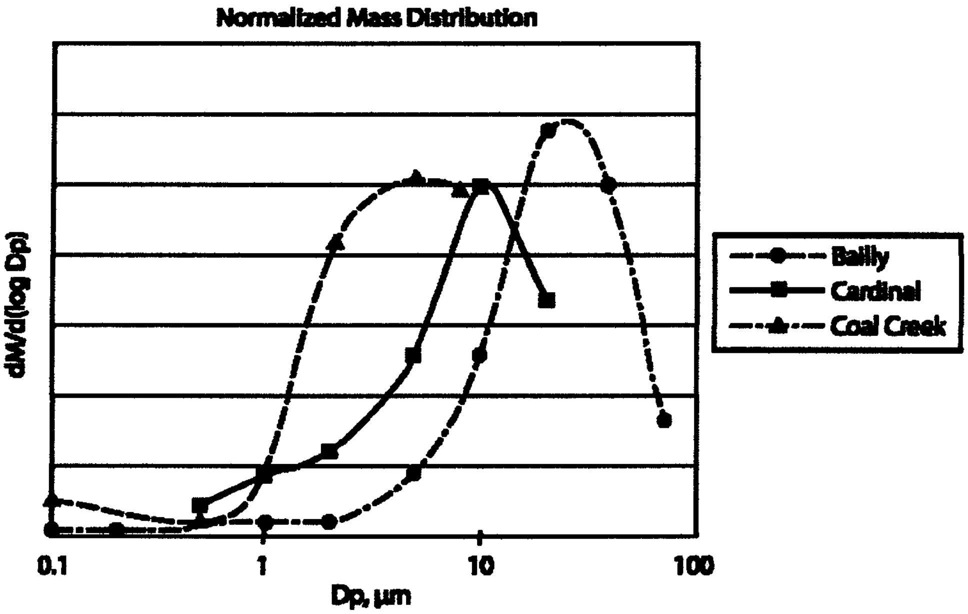
Table 4. Chemical Composition of the Spike Shown in Figure 12 and the Filter (weight percent expressed as equivalent oxide).

Oxide	**100% Coal A**	
	Spike	**Filter**
Na_2O	**35.1**	17.3
MgO	1.4	7.8
Al_2O_3	2.0	9.8
SiO_2	9.1	10.6
P_2O_5	0.4	0.2
SO_3	**39.7**	28.0
K_2O	2.6	1.5
CaO	6.2	15.7
TiO_2	0.2	1.8
Cr_2O_3	1.4	0.1
Fe_2O_3	0.9	2.9
BaO	0.5	2.6

In addition to the aforementioned testing results, penetration of submicron particles through ESP and scrubbers has been reported by numerous researchers (Markowski and others, 1983, and Lighty and others, 2000). Figure 13 shows the penetration of particulate from ND lignite to be the highest of the combustion systems tested as part of the DOE field test program.



Plant	Description	Stack Emissions
Bailly	345 MW, Cyclone Burner Dry scrubber, ESP Illinois high-sulfur bituminous	60 kg/hr
Cardinal	615 MW, well-mounted cell burner ESP, no sulfur removal Pittsburgh No. 8 bituminous	100 kg/hr
Coal Creek	550 MW, tangential-fired Wet scrubber, ESP North Dakota lignite	260 kg/hr

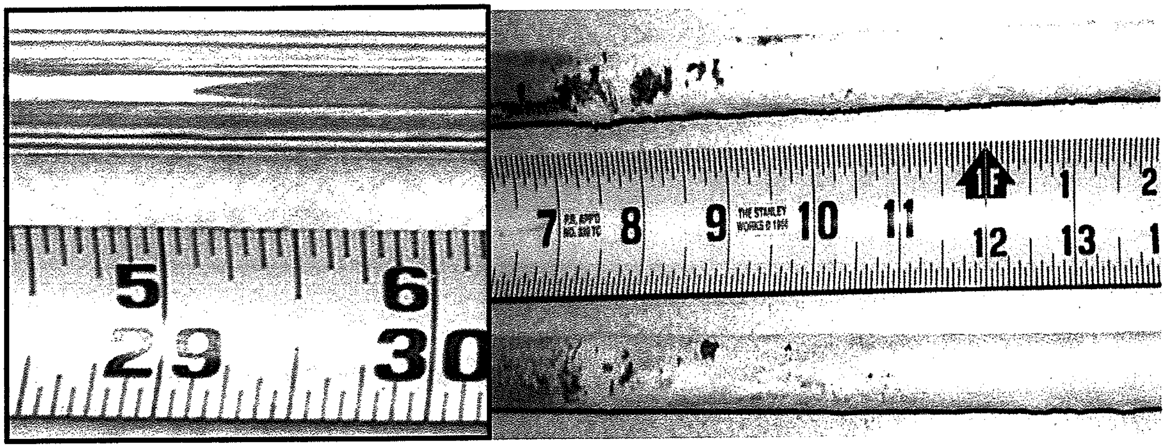
Powerspan Testing at MRYS

The Powerspan slipstream electrocatalytic oxidation (ECO) reactor system was designed by Powerspan and the EERC (Tolbert and Benson, 2008). The slipstream system was installed by the EERC at Minnkota Power Company's Milton R. Young Station Unit 1 downstream of the ESP where the flue gas temperature ranged from 300°F to 350°F. The dielectric barrier discharge (DBD) reactor has quartz electrode rods inside where electric current is passed in order to generate the plasma used to oxidize nitrogen oxide (NO) to nitrogen dioxide (NO_2). The temperature of the quartz electrodes was approximately 100°F higher than the gas temperature. The system at MRYS was commissioned on July 3, 2007, and it operated for 107 days. Operational performance of the system was monitored and data were archived for post processing. A pair of electrodes was extracted and replaced on a bi-weekly basis. Each pair of electrodes was shipped to Powerspan for testing in their laboratory reactor for NO conversion testing. Tested electrodes were then shipped to the EERC for scanning electron microscopy imaging and x-ray microanalysis. Measurement of NOx conversion in the field by the slipstream system was not possible due to the nitric acid production of the DBD reactor. Aerosols passing through the ESP at MRY Unit 1 resulted in significant accumulation on Powerspan's slipstream ECO barrier discharge reactor rods resulting in significant degradation in performance.

The operational observations, performance results, and lab testing showed that the system was adversely affected by ash fouling. NOx conversion by ash covered electrodes was significantly reduced. Figure 14 visually compares a clean unexposed quartz rod to one exposed to flue gas and aerosols downstream of the ESP at MRY Unit 1. The abundance of sodium in lignite coal fired during the Powerspan testing at MRYS is shown in Figure 15. The results show sodium levels measured by the full stream elemental analyzer (FSEA) ranged from 3.5 to 6 % Na_2O in ash. Figure 16 shows the degradation in NO conversion measured during subsequent lab testing at EERC using the exposed quartz rods removed from the slipstream test ECO DBD reactor at MRYS as a result of being coated with aerosols. The NO conversion was severely impacted.



A. Clean quartz rod.

13-Sep	I G	9 7	86	B3 B4	35
27-Sep	E L	5 12	100	B5 B6	21
11-Oct	NO SAMPLES EXTRACTED DUE TO THE PROXIMITY TO THE FINAL SAMPLING.				
18-Oct	A N	1 14	107	All of the electrodes listed above will be removed for lab testing and analysis.	

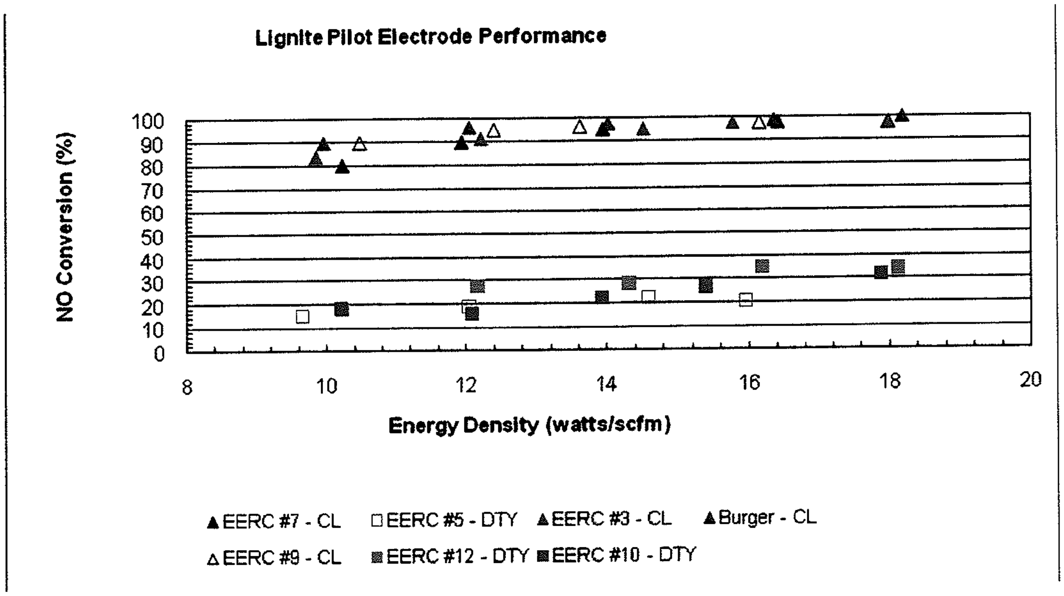

Figure 16. NO conversion for clean (CL) and dirty (DTY) for quartz tube exposed the flue gas during the MRYS testing. Burger is a slipstream pilot ECO system in Ohio used for reference.

Examination of the quartz rods removed from the slipstream ECO DBD reactor at MRYS (cross-sectioned to expose coating thickness) by EERC using scanning electron microscope equipped with an x-ray analyzer showed significant elemental sodium, sulfur, and calcium in the ash coating the tubes after only 16 days of testing. The data is reported on Figure 17. The thickness of the layer was approximately 25 µm. A sonic horn was used for in-service cleaning of the rod-tube deposits. Images of the reactor and coatings on the electrodes are shown in Figure 18.

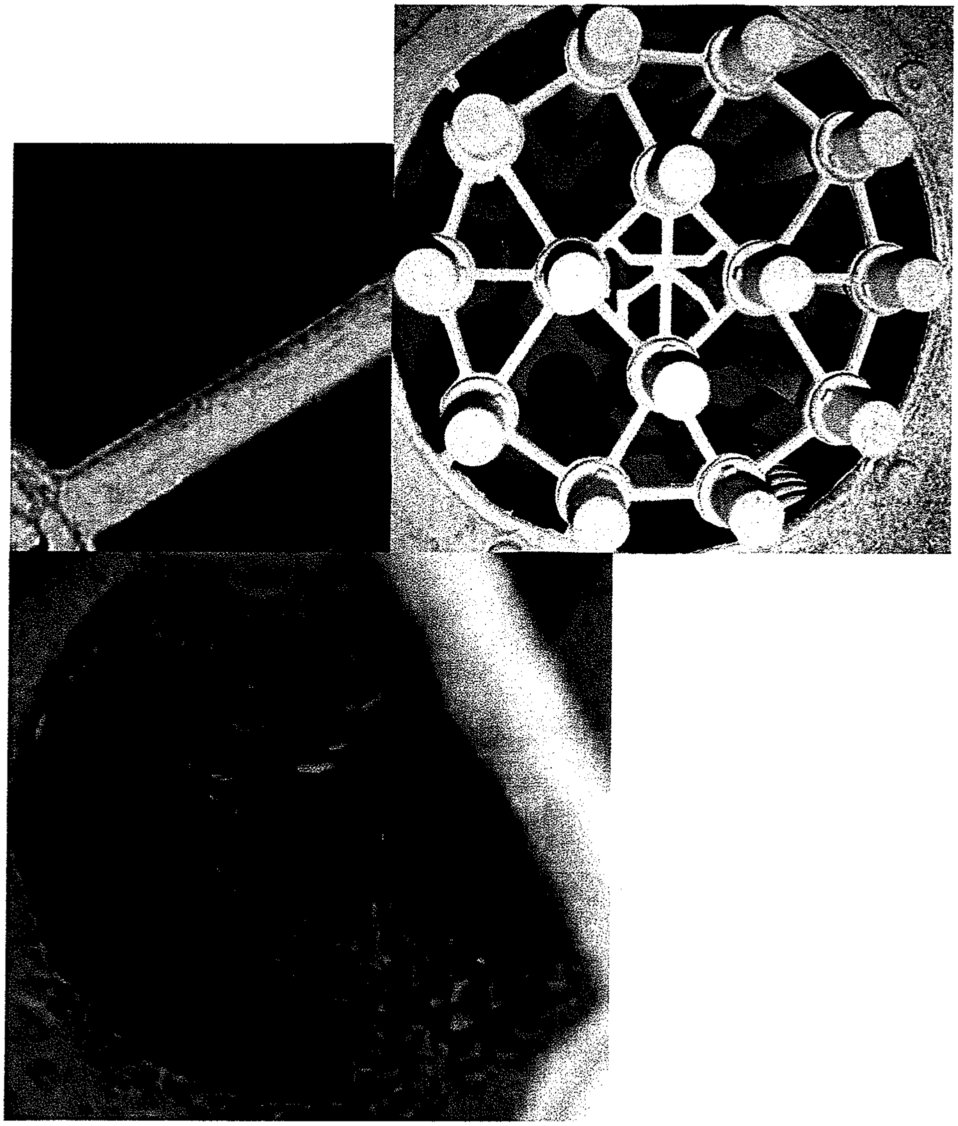

Figure 18. Images of top of slipstream ECO DBD reactor at MRYS showing ash accumulations on electrodes and reactor surfaces.

Conclusions gained by this work are:

1.) Sodium rich aerosols and small ash particles that had penetrated the ESP accumulate and become bonded on the surface of the silica electrodes despite using a sonic horn as recommended by Powerspan.

2.) Ash accumulations adversely affected the NOx conversion.

3.) The adverse impact occurs within a two week time period.

MRY Sulfate Aerosol Sampling

The penetration of aerosols through ESP and wet scrubbers is well known and has been studied since the mid 1970s (McCain and others, 1975; Ensor and others, 1975). As a result of these challenges, the quantity of total aerosols and sulfate aerosols was measured at MRYS by Markowski and others, 1983. Markowski and others (1983) collected EPA method 17 particulate samples and size segregated the particles using an impactor that aerodynamically separates particles and allows for the characterization of each fraction. The results of the EPA method 17 samples conducted over a four day period. The mass concentrations of aerosols as determined by EPA method 17 sampling are illustrated in Figure 19 for the inlet and out of the scrubber. At the inlet aerosol mass concentrations ranging from a high of over 10,000 μg/m^3 to a low of 4000 μg/m^3. Significant levels were also found at the scrubber outlet ranging from 8800 to 2500 μg/m^3. The removal efficiency varied from -25 to 66%. Markowski and other (1983) offered no explanation of the differences in the levels of aerosols measured in the flue gas and removal efficiency. They did not consider that the ash content of the coal varied significantly during the testing. Results of testing at MRYS have shown significant differences in the quantity vaporized for coals that have different ash contents (see Figure 3). The variations in ash content shown in Figure 19 reflect changing coal characteristics that resulted in differences in aerosol mass concentration.

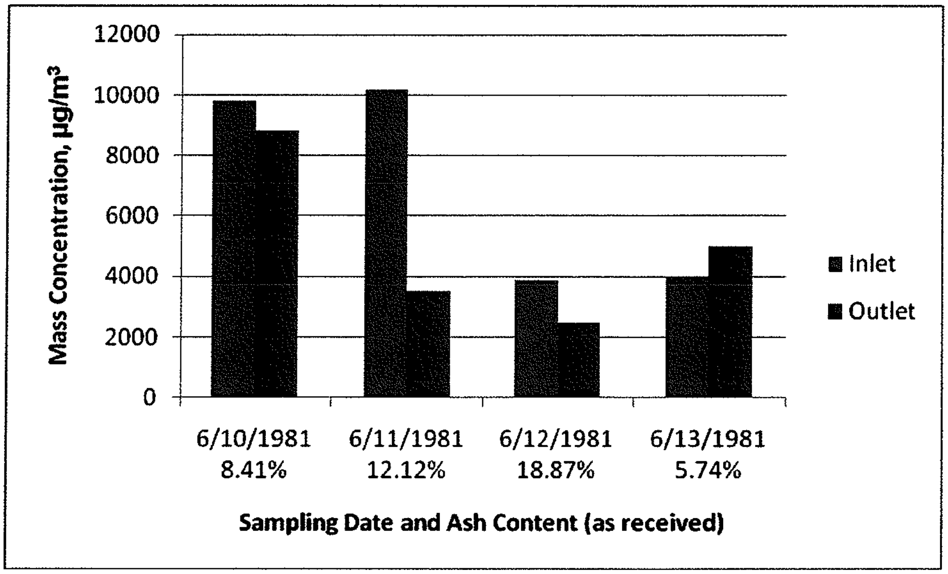

Figure 19. Mass Concentration of Aerosol Collected at MRYS Unit 2 at the Scrubber Inlet and Outlet (Markowski and others, 1983).

The results of the measurements of aerosol capture are illustrated in Figure 20. The results show that aerosols less than one micrometer in diameter are not effectively captured in the wet FGD at the MRY facility. The graph also indicates the penetration of the particles through the FGD as a function of particle size. The penetration is the outlet size distribution divided by the inlet size distribution. (Penetration = 1- efficiency). Markowski and others (1983) showed that the "metallic" sulfate aerosols (sodium sulfate) penetrated the FGD much more effectively than the larger particulate materials.

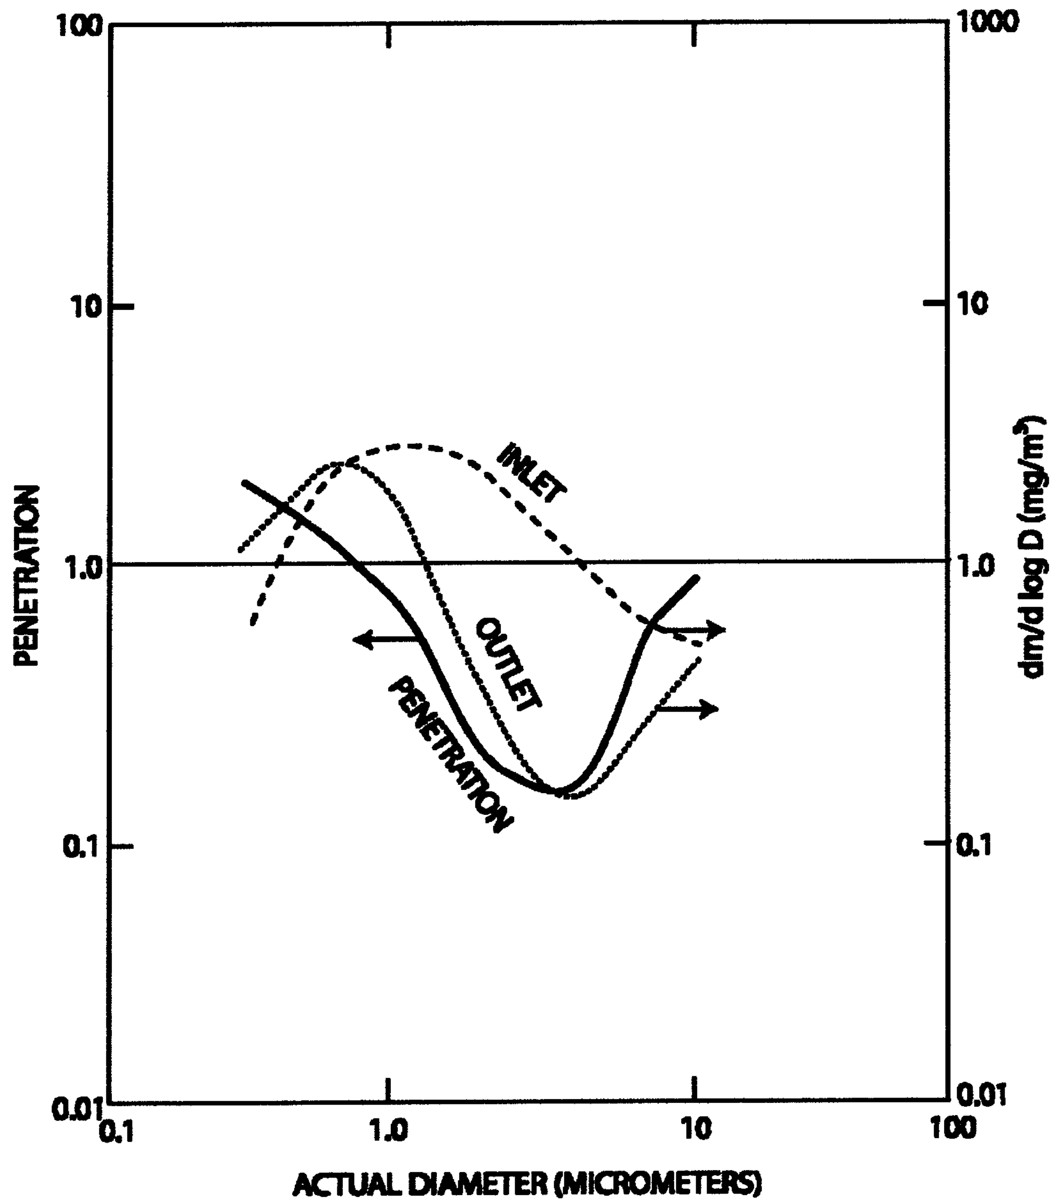

Figure 20. Penetration through the MRYS Unit 2 wet scrubber (Markowski and others, 1983).

The mass of each of the impactor size fractions for the aerosols collected at the inlet and the outlet of the wet FGD upstream and downstream of the MRYS Unit 2 scrubber are illustrated in Figure 21 and 22 with the results tabulated in Table 5. The total mass distributions are summarized in Figure 21 and the sulfate mass distribution is illustrated in Figure 22. Based on the impactor data the total mass of particulate that penetrates the scrubber is 5990 μg/m^3 (Markowski and others, 1983). These ash materials consist of a combination of sulfates and oxides of sodium, calcium, and sulfur. Much of the aerosol is present in the >14 μm size fraction. There are also significant mass in the less than 1 μm size fraction that has the potential to penetrate the pores of the catalyst. In addition, there is a significant mass in the <0.26 μm fraction. This fraction represents the ultrafine component that has been implicated as the most significant contributor to catalyst poisoning (Kling and others, 2007).

Table 5. Size segregated total and sulfate particulate collected upstream and downstream of the MRYS FGD (Markowski and others (1983).

Size, μm	Inlet Total, μg/m^3	Outlet Total, μg/m^3	Inlet Sulfate, μg/m^3	Outlet Sulfate, μg/m^3
<0.26	1910	769	436	602

6. Determination of Sodium Loading Adversely Affecting SCR Catalyst Performance

Alkali metals such as potassium and sodium are known poisons and blinding agents for SCR catalysts used for NOx emissions control. As previously discussed (Burns & McDonnell and others, November 2008) and repeated above, there will be submicron sodium, likely in sulfate form, emitted from the dry ESPs at MRYS that will contaminate SCR catalyst located in a low-dust or tail-end configuration. The first fundamental issue is "how to estimate the amount (mass rate) of sodium and in what size range could be emitted from the boilers at MRYS, for the purposes of a BACT analysis". Because BACT analyses on existing sources are not common, we also presume them to be "studies on paper using available information". We do not consider BACT analyses as research projects requiring design of experiments, site-specific testing, and development engineering for the control technique being considered. Thus, this first issue is a significant challenge.

The second fundamental issue is "for the purposes of a BACT analysis, what rate of catalyst deactivation is likely to occur as a result of exposure to the expected particle or aerosol size range and concentration of sodium emitted from a boiler over a given period of time?"

Only by assuming that these fundamental issues can be resolved with the degree of certainty required for purposes of a BACT analysis, can such a comparison then be performed that could lead to a basis of technical feasibility of low-dust and tail-end SCR technology for MRYS.

Because most coals fired in utility boilers do not have the high sodium content of North Dakota lignite, and because cyclone boilers fire at high temperatures which promotes the emission of submicron sodium aerosols, there is not much published technical information that is available to help answer these fundamental questions. We can gain some insight into what might happen to SCR catalyst exposed to flue gas containing significant amounts of alkali salts by looking at the impact of co-firing biomass such as straw or switchgrass with coal. This is increasingly important to utilities that have chosen to pursue such a fuel mix strategy who also employ SCR technology on their boilers. We have previously commented on the high-dust SCR catalyst experience at the Avedore plant (Burns & McDonnell and others, November 2008) and the high frequency of catalyst washing performed to counteract the apparent highly negative impacts of biomass cofiring.

7. Alkali Aerosol Loading and Catalyst Deactivation

There is evidence that alkali aerosol loading in the flue gas streams results in catalyst deactivation. The total and sulfate aerosol mass loading measurements were conducted by Markowski and others (1983) at the inlet and outlet of the wet FGD scrubber at MRYS Unit 2.

The key data obtained by Markowski and others (1983) is illustrated in Figure 23 as well as the size fractionated data in Figures 21 and 22 provide information on loadings. The data provided shows a range of mass concentrations up to 8800 μg/m^3 at the outlet of the scrubber based on EPA method 17. Based on results in mass size distribution of the aerosol, 47 to 80% of the aerosols that pass through the scrubber are less than 1.1 μm. Much of this material is in the ultrafine fraction. These materials have the potential to penetrate into the catalyst, causing plugging, and can react with active components in the catalyst. There are numerous publications supporting these mechanisms. Kling and others (2007) found that the rate of catalyst deactivation was related to the accumulation of sodium and potassium on the catalyst as shown in Figure 24 and 25. The work by Kling and others (2007) is consistent with the work conducted by Khodayari, 2001 illustrated in Figure 26 where he shows that the deactivation rate is more significant for PC-fired systems as compared to fluidized beds. The work based on Kling and others (2007) when applied to PC and cyclone-fired systems will likely underestimate the degree of catalyst deactivation because of the firing methods.

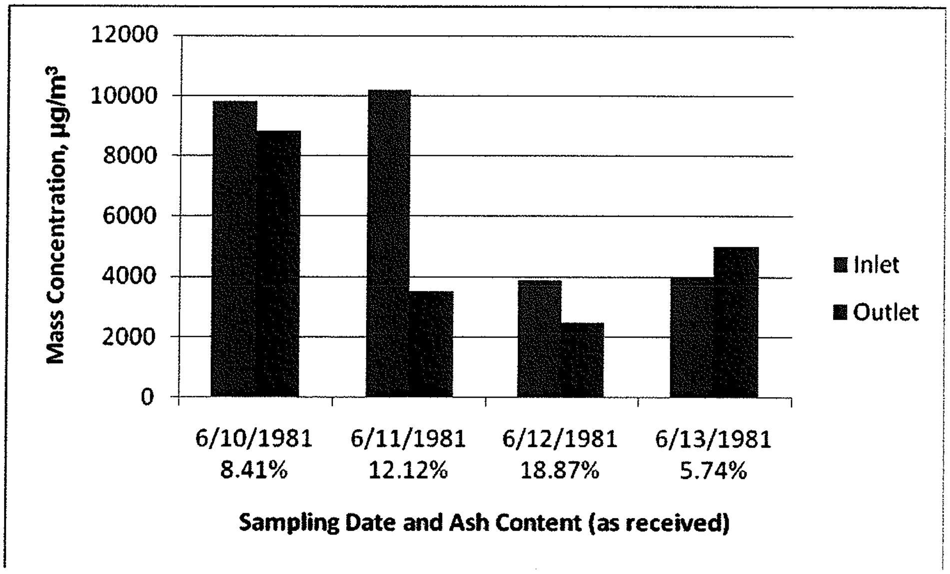

Figure 23. Mass Concentration of particulate collected at MRYS using EPA Method 17 (Markowski and others, 1983).

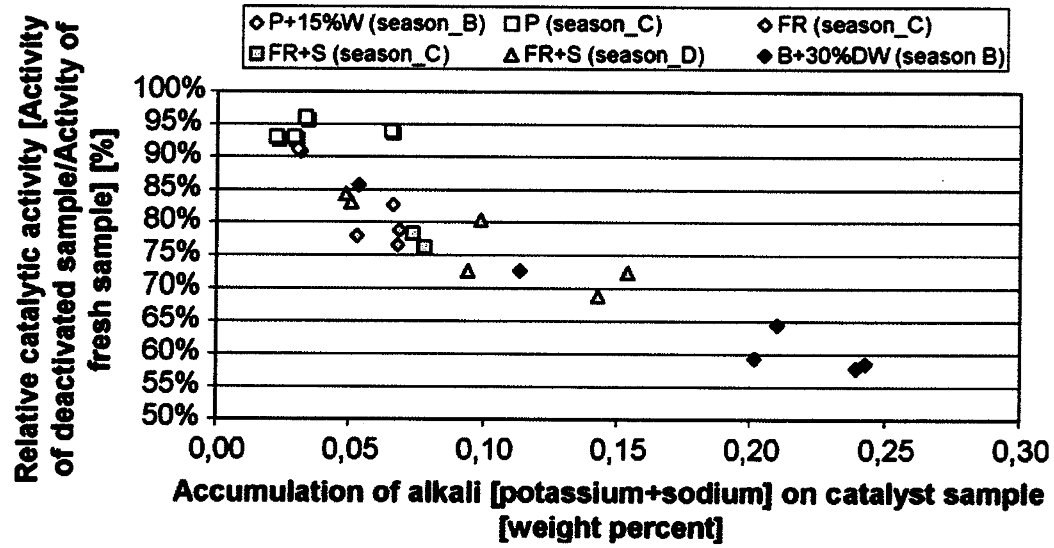

Figure 24. Catalyst deactivation compared to accumulation of potassium and sodium on the catalyst surface (Kling and others, 2007).

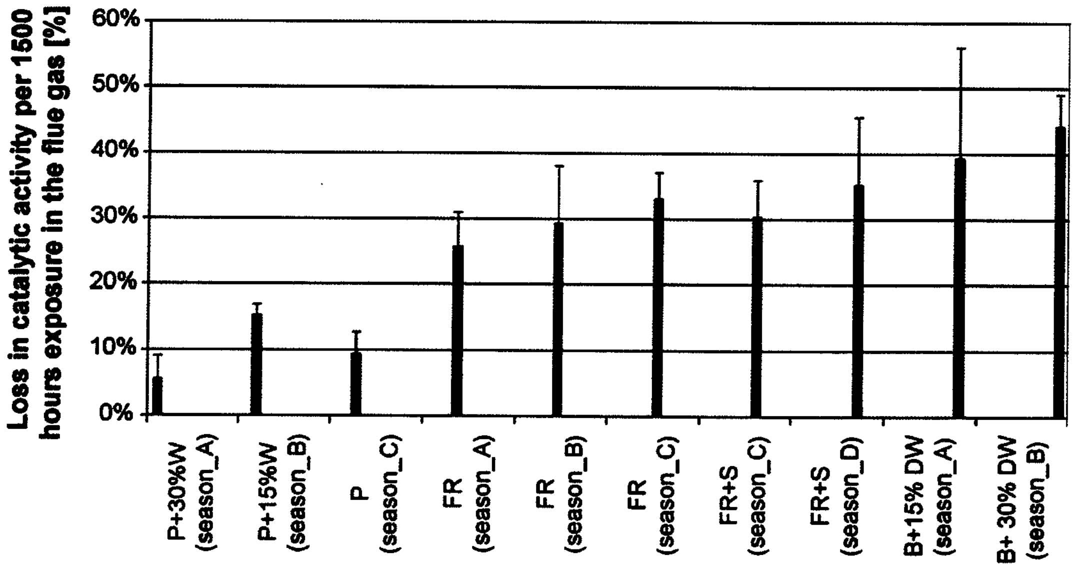

Figure 25. Loss in catalyst activity when exposed to flue gases containing vaporized Na and K when combusting biomass in a fluidized bed combustion system (Kling and others, 2007).

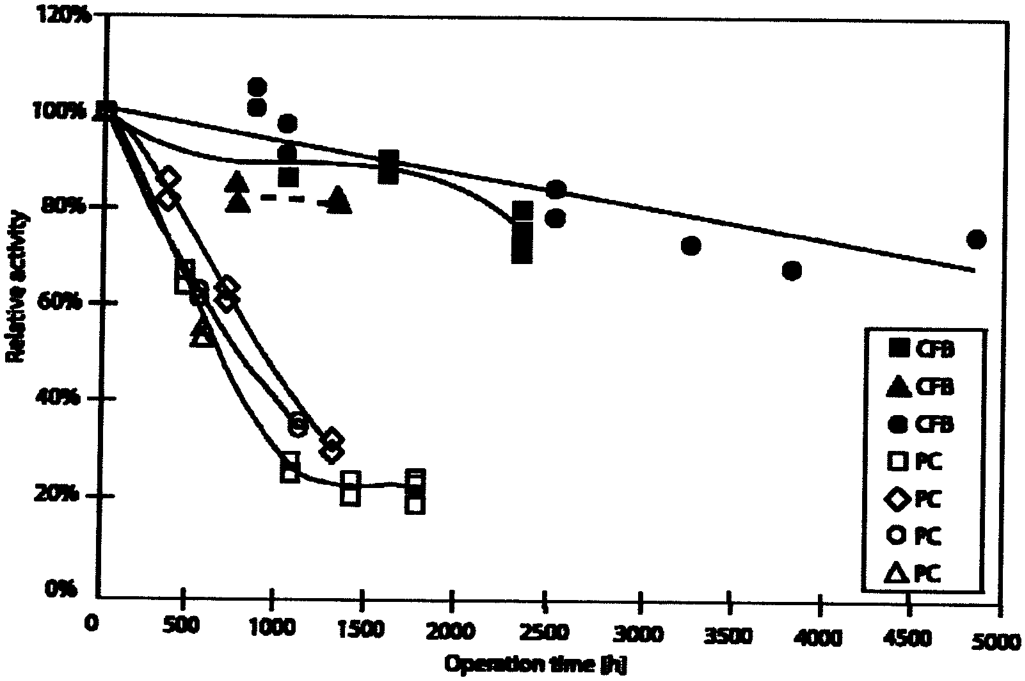

Figure 26. Comparison of poisoning of catalysts in a CFB boiler firing forest residues and in a PC firing pulverized wood (Khodayari, 2001).

There is a direct relationship to the concentration of sodium and potassium in the flue gas with accumulation on the catalyst and subsequent deactivation. The deactivation shown in Figures 24 and 25 directly relates the accumulation of sodium and potassium on the catalyst with deactivation. Deactivation rates of 40 to 55 percent (considering the error bars) was measured on catalyst that had accumulated 0.25 wt % sodium and potassium on the catalyst surface when exposed to flue gas containing 22,500 μg/m^3 sodium and potassium for only 1500 hours. The flue gas downstream of the scrubber at the MRYS Unit 2 has been shown to contain aerosols at levels of 8800 μg/m^3 with about 50% of the mass being less than 1.1 μm. The ash that exits the ESP on Unit 1 is dominated by sodium and sulfur based on the results from the Powerspan testing. The quartz elements exposed to the flue gases for 16 days (384 hours) were completely covered with sodium and sulfur rich ash (see Figure 17). These elements were exposed to cleaning using a sonic horn. The sodium and sulfur rich ash produced a dense layer on the surface of the quartz rods approximately 25 μm thick in 384 hours. The MRYS results along with research efforts conducted in Europe show that masking and poisoning of SCR catalysts from flue gases containing alkali aerosols is a significant problem that has not been overcome by SCR catalyst vendors.

8. Experience of ESP/FGD Equipped Utility Plants Co-Firing Biomass and Coal with TESCR

In previous communications to NDDH, it was stated that no recent TESCR installations had been completed on utility boilers anywhere in the world. Burns & McDonnell subsequently learned about the Amager facility currently under construction in Copenhagen, Denmark that will involve a TESCR system on a multiple fuel-fired boiler that is expected to burn combinations of pulverized coal, wood pellets, straw, and fuel oil. A technical paper written by Haldor Topsoe described the design efforts for SCRs on biomass (straw)-fired boilers (Crespi, and others, 2008) and indicated that the TESCR configuration was chosen specifically to address the concerns about catalyst poisoning due to the constituents of the straw (notably potassium). Follow-up communications were initiated by Burns & McDonnell with Haldor Topsoe, which supplied the catalyst for Amager's TESCR reactor; Alstom, which was the supplier of the SCR reactor system and the Flowpac wet FGD system (see attached project summary); and a plant engineer for the boiler's operator (Vattenfall A/S) (Burns & McDonnell personal communications, 2009). These personal communications provided the following information about this installation:

a. The boiler is wall-fired and can be fired with oil (start-up), coal and wood- and straw-pellets. Coal and bio-pellets are pulverized in mills [prior to firing in the boiler], with full flexibility from 0 to 100 % straw. It is expected to fire 100% biomass most of the time. Maximum heat input to the boiler is 350 MW during coal and oil firing and 300 MW during wood/straw pellets firing.

b. Danish regulations on emission include an emission fee (\$/ton of SO_2 or NO_x emitted), therefore the utility looks for the best compromise between low cost fuel and low emissions. The utility wants to be able to fire any mixture as specified above for the flexibility of cost and availability of both straw and coal. This is common for European customers who have to balance carbon dioxide (CO_2) emissions. When a new plant is built, the utility wants to make sure it can fire any fuel that may come on the market in the coming years without being limited by his boiler and cleaning equipment. Of the biofuels, straw is considered to be the most difficult as compared to woodchips, saw dust, paper, etc. The situation is the same in Sweden, Holland and some other countries.

c. At the planning stages of the Amager project it was expected to co-fire biomass and coal in the boiler. Now, if bio-mass fuels are not available, 100% coal will be fired. When bio-mass is fired, NOx emissions are expected to be low, so the utility is allowed to bypass the flue gas cleaning system. According to European regulations, the NOx emission limit with bio-mass is 300 mg/Nm^3 (dry 6% O_2). Both the FGD and the SCR systems will be bypassed, if NOx in the flue gas emitted from boiler is below 300 mg/Nm^3. No dampers are installed upstream of the TESCR. There is a global by-pass of both FGD and TESCR systems. The wet FGD and TESCR are mainly needed for any coal firing flue gas cleaning. When pure straw/ biomass is fired the whole wet FGD and SCR system can be bypassed, saving a lot of operating cost as both SOx and NOx will be within the limits from the authority. The client was not sure that they could get enough of straw available at an acceptable price, so the boiler had to have great fuel flexibility.

Based on this information, it appears that the Amager plant's TESCR system will typically be bypassed when the fuel firing conditions are most difficult for the SCR catalyst with regard to poisons. Consequently, Burns & McDonnell does not believe the Amager facility project under construction provides any indication that TESCR technology is technically feasible for application to MRYS.

9. Relevance of Recent TESCR investigations at We Energies' South Oak Creek Station

Recently, in response to a Consent Decree that requires the installation of SCR technology on Units 5, 6, 7 and 8 at its South Oak Creek Generating Station in Oak Creek, Wisconsin, We Energies (Wisconsin Electric) has investigated the use of TESCR technology. The investigation ultimately led to the determination that the TESCR approach would not be used. Based on information obtained by Burns & McDonnell from the engineering consultant and the technology vendor for that project (Burns & McDonnell personal communications, 2009), the decision not to use TESCR technology was based on economics. However, the fact that TESCR systems were considered to be feasible for specific application at the South Oak Creek units is not indicative that the same technology would be technically feasible for application at MRYS. This is due to the substantial differences between the South Oak Creek boilers and the MRYS boilers, as summarized in the Table below:

Table 6. Comparison of Boilers for South Oak Creek and Milton R. Young Station

	South Oak Creek	**Milton R. Young**
Fuel Type	PRB Coal (low ash, very low sulfur)	ND Lignite
FGD Design Fuel Sulfur Content, SO_2 lb/mmBtu	1.15	3.95
Firing Type	PC wall-fired (Units 5 & 6) PC tangential (Units 7 & 8) (dry bottom)	Cyclone fired (Units 1 & 2) (slagging-type, wet bottom)
Design Boiler Outlet NOx lb/mmBtu	0.15	0.51 (Unit 1 w/ASOFA) 0.49 (Unit 2 w/ASOFA)
Consent Decree NOx Limit lb/mmBtu	0.10	TBD

The significant differences in the ash characteristics, especially with regard to the sodium content, between PRB coal and North Dakota lignite have been explained in previous submittals to NDDH (Burns & McDonnell and others, 2007 and 2008). The effect that cyclone firing has on the partitioning of sodium has been explained previously, and reiterated in this document. In addition, it can be seen from the tabulation above that the SO_2 content of the flue gas will be up to four times as high at MRYS as at South Oak Creek, either before or after the FGD system. This means that the potential for deposition of ammonium bisulfate on the SCR catalyst, due to the reaction between the ammonia reagent and the SO_3 that forms within the SCR reactor when catalytic SO_2 oxidation occurs, will be proportionally much greater for the application of TESCR technology to MRYS than it would have been at South Oak Creek. Finally, it should be noted that compliance with the Consent Decree for NOx emissions in the case of South Oak Creek required only a moderate degree of emission reduction in the SCR systems, meaning that the design was not particularly challenging from a percentage reduction standpoint.

10. Relevance of Ongoing LDSCR Installation Project at We Energies' South Oak Creek Station

Following the elimination of TESCR systems from further consideration for the SCR retrofits required by the Consent Decree, We Energies is proceeding with the installation of LDSCRs at Units 5, 6, 7 and 8 at South Oak Creek. Again, as shown in Table 6, the significant differences between the fuel, firing type, sulfur content and NOx reduction requirement support the contention that installation of LDSCR systems under construction at South Oak Creek does not constitute a demonstration that LDSCR technology is technically feasible for MRYS.

11. Relevance of Existing LDSCR Installation at PSEG Mercer Station

In response to a January 2002 Consent Decree that required the installation of SCR technology on Units 1 and 2 at its coal-fired electric generating station in Mercer County, New Jersey, PSEG Fossil (PSEG) has installed and operated LDSCR systems at this site since 2004 (Unit 2) and 2005 (Unit 1). However, the fact that LDSCR was considered to be feasible for specific application at the Mercer units is not indicative that the same technology would be technically feasible for application at MRYS. This is due to the substantial differences between the Mercer boilers and the MRYS boilers, as summarized in the Table below:

Table 7. Comparison of Boilers for Mercer and Milton R. Young Station

	Mercer	**Milton R. Young**
Fuel Type	Low-sulfur bituminous coal (Venezuelan and eastern U.S. blend)	ND Lignite
Firing Type	PC wall-fired, slagging-type (wet bottom)	Cyclone fired (slagging-type, wet bottom)
Design Boiler Outlet NOx lb/mmBtu	1.40 (prior to controls) (see note below)	0.51 (Unit 1 w/ASOFA) 0.49 (Unit 2 w/ASOFA)
Consent Decree NOx Limit lb/mmBtu	0.10	TBD

Mercer has demonstrated and employed various NOx reduction techniques before LDSCR installation in 2004, primarily SNCR, with and without fuel-lean gas reburn, and in-duct SCR.

The significant differences in fuel type and firing type between these two plants would create very different flue gas characteristics of the flue gas entering the LDSCR, especially with regard to the sodium aerosol. The significant differences in the ash characteristics, especially with regard to the sodium content, between bituminous coal and North Dakota lignite have been explained in previous submittals to NDDH. The effect that cyclone firing has on the partitioning of sodium has also been explained previously, and reiterated in this document.

12. Additional Technical Feasibility Issues for TESCR at MRYS

As noted in previous submittals to NDDH (Burns & McDonnell and others, September and November, 2008), there are no existing or planned TESCRs on coal-fired utility power plants in the U.S. A review of the TESCR applications on German coal-fired power stations has indicated that these installations are configured basically as shown in the diagram on page 1 of this document. That is, flue gas from the outlet of the wet flue gas desulfurization (FGD) system absorber is reheated prior to entering the TESCR system, using a regenerative (Ljungstrom type) gas-to-gas heat exchanger (GGH) that supplies heat that was extracted from the flue gas upstream of the FGD. According to consultation with the designers of the LDSCR systems for South Oak Creek, the expected leakage through this type of heat exchanger will be at least 5.0 percent. When flue gas leaks across this "FGD GGH" from the inlet to the outlet flue gas stream, it effectively bypasses the FGD absorber, meaning that no SO_2 removal takes place from this slipstream of the total flue gas.

In the case of both MRYS Unit 1 (in the CD) and Unit 2 (in the proposed BART), NDDH has indicated that 95% SO_2 removal is required. This will preclude the use of this type of GGH, because, as leakage around the FGD system approaches five percent, it becomes ***impossible*** to achieve 95% overall SO_2 removal. This was not an issue for the German FGD systems, which were not required to achieve the same high level of SO_2 removal efficiency that is dictated by the MRYS CD and the proposed SO_2 BART.

This leakage could be avoided if the saturated flue gas from the FGD system absorber were sent directly to the "SCR GGH" upstream of the TESCR reactor as shown in the diagram on page 1. However, according to the engineering consultant who performed the evaluation of TESCR technology at South Oak Creek (as described in Section 9 above), "Saturated flue gas tends to be corrosive and there is virtually no experience with Ljungstrom GGH handling corrosive saturated gas. Saturated gas from the absorber tower carries gypsum slurry droplets, which tend to plug the cold end of the GGH with gypsum deposits that are extremely difficult to clean on-line."

Another aspect of the TESCR approach that appears infeasible at MRYS is that the flue gas would enter the new fiberglass reinforced plastic (FRP) ductwork leading to the respective chimneys, and Unit 2's FRP chimney liner, at a normal temperature above the 200°F design limit, due to the TESCR reactor's outlet temperature being above 500 °F entering the treated-side of the SCR GGH.

Based on these considerations, the only way to apply TESCR technology to the units at MRYS while providing high SO_2 removal would be to employ a flue gas reheating technology which has not been proven in the application to a TESCR system at any full scale power plant installation. This indicates that TESCR technology is technically infeasible for application to the Units at MRYS.

13. Summary and Conclusions

- Because of the unique properties of Fort Union Lignites, they produce more vaporized ash (Na and other elements) that other coals including PRB and bituminous coal.
- Higher combustion temperatures associated with cyclone firing result in more ash vaporization and increased levels of submicron fine and ultrafine aerosol particles.
- Cyclones reduce the quantity of coarse flyash particles in the flue gas available to provide sites for sodium condensation and to dilute the bonding effects of the aerosols once deposited on a surface.
- The particle collection efficiencies for fine particles less than 1 µm are poor for both ESP and wet FGD, such as those utilized at MRYS.
- The number of flue gas particles per gram increases ten times for 1 µm versus 10 µm and another ten times for 0.1 µm versus 1 µm (diameter), so the fine and ultrafine aerosols are plentiful in number because of penetration through ESPs and scrubbers. These fine particles have high surface areas, are highly reactive, and readily bond together because of high surface energies.

- Particles in the 0.1 to 1.0 μm size fractions are largely composed of condensed vapor phase species such as sodium, potassium, and sulfur.
- Sodium-rich aerosol particles present in flue gas downstream of the ESP at MRYS Unit 1 significantly impacted the performance of the Powerspan slipstream ECO barrier reactor system in less than two weeks of exposure.
- Sodium- and sulfur- rich coatings on the surface of the Powerspan quartz rods were dense, continuous, and difficult to scrape off. These sodium and sulfur rich layers were produced in only 384 hours and were 25 μm thick.
- Emission rates downstream of ESP described in the reports provided by the NDDH range from 4,500 to 50,000 μg/Nm^3. The particulate emitted are dominated fine and ultra fine aerosols rich in sodium and potassium. NOTE: The level of 22,500 μg/Nm^3 of sodium- and potassium-rich fly ash derived from biomass firing resulted in catalyst deactivation of 30 to 40 % in 1500 hours (King and others, 2007).
- These are no TESCR installations in the U.S. on utility coal-fired boilers, and there are no examples of TESCR technology being applied worldwide on any coal-fired boilers having the same high percentage SO_2 removal requirements that are applicable at MRYS. The heat exchanger technology that has been employed on other TESCR systems for bituminous coal-fired boilers located in Germany, if applied at MRYS, will preclude compliance with the established SO_2 removal requirements.
- The expected outlet temperature from the TESCR and downstream gas-to-gas heat exchangers will be too high for the fiberglass flue gas ductwork exhausting the chimneys at MRYS.
- The existing LDSCR installations in the U.S. are on units firing coals and using coal firing technology that will not produce the same high level of catalyst poisons in the flue gas as would be the case at MRYS, where both units are cyclone furnaces firing high-sodium lignite.

Conclusions

In the end, arguments regarding the technical feasibility of tail-end and low-dust SCR technology at Milton R. Young Station are reduced to disputing the characterization of the gas stream characteristics and the impacts of those characteristics on boiler and emissions control operations. Those who suggest that these impacts can be resolved by the use of LDSCR and TESCR, and that such technology will work at MRYS without failure, cannot point to relevant data showing success at other coal-fired boiler SCRs which have such high levels of sodium in the fuel and the flue gas stream.

Considering the findings and conclusions presented above and previously, low-dust and tail-end SCR technology would not be available to apply to Units 1 and 2 at MRYS without extensive long-term pilot-scale testing and design development efforts. As BACT is not the selection of a pollution reduction technology that requires such research and development in order to determine if it can be successfully deployed for full-time, full-scale operation, we believe that low-dust and tail-end SCR technology is not technically feasible at MRYS for Unit 1 and Unit 2 NOx emissions control (Arfmann and others, 2007).

4.0 SUPPLEMENTAL NOx BACT ANALYSIS CONTROLS & COSTS – MRY STATION UNIT 2

This supplement to the NO_X BACT analysis for Milton R. Young Station (MRYS) Unit 2 has been prepared in response to a request of the North Dakota Department of Health[1]. The NDDH requested completion of a "full" BACT analysis for two specific technologies that had been eliminated at step 2 of the BACT analysis process[2] in the October 2006 NO_X BACT Analysis Study report[3]. These two technologies are low-dust selective catalytic reduction (SCR) and tail-end SCR. The approach taken in this supplemental NO_X BACT Analysis Study report for MRYS Unit 2 includes ranking by control effectiveness and an impacts analysis of alternate control technologies for NO_X emissions that follows the third and fourth steps of a "top down" BACT analysis as described in the EPA's Draft New Source Review Workshop Manual[4]. The initial NO_X BACT Analysis Study for Milton R. Young Station identified potentially available NO_X control techniques and technologies, summarized in Table 3-3[5] of the October 2006 report. Commonly-applied and novel NO_X control techniques and technologies, including a technical description of the specific emission reduction processes and capabilities, were summarized in Section 3.2[6] and detailed in Appendix A1 of the October 2006 NO_X BACT Analysis Study report. This supplemental analysis report does not include the details of the technical feasibility discussion previously provided in the initial NO_X BACT Analysis Study report for MRYS Unit 2.

SCR technology is considered technically infeasible by Minnkota for application at MRYS, so this information for the hypothetical application of low-dust and tail end SCR alternatives is included for comparative purposes only. Cost estimates and emission rates shown for such hypothetically-applied SCR systems are based on assumptions that known or expected reasons for technical infeasibility for installation, operation and maintenance of the SCR equipment on this boiler are solvable. There is no available information on recently-completed similar tail-end or low-dust SCR projects on coal-fired powerplants in the United States that could be used, with adjustments, to represent total installed costs that could be expected for MRYS Unit 2. Site-specific needs and challenges identified for applying tail end and low-dust SCR technologies to Milton R. Young Station Unit 2 significantly influence the capital cost estimate for variations of these hypothetical applications of SCR alternatives. Furthermore, the

---

[2] As described in the EPA's Draft New Source Review Workshop Manual. See Reference number 2, October 1990.
[3] See Reference number 3, October 2006. This Supplement commences with Section 4.0, which places it at the end of the October 2006 Analysis, which ended at Section 3.5.2.
[4] As described in the EPA's Draft New Source Review Workshop Manual. Ibid Reference number 2, October 1990.
[5] Ibid Reference number 3, October 2006, page 3-5.
[6] Ibid Reference number 3, October 2006, page 3-6 through page 3-13, and pages A1-1 through A1-55.

"EPA Air Pollution Control Cost Manual" is not applicable for use in estimating control equipment costs for these hypothetical applications of SCR technologies, as the EPA Control Cost Manual states:

> "The costs for the tail-end arrangement, however, cannot be estimated from this report because they are significantly higher than the high-dust SCR systems due to flue gas reheating requirements."[7]

This requirement for flue gas reheating also applies to the hypothetical application of low-dust SCR to MRYS, due to the cold-side arrangement (downstream of the electrostatic precipitator) instead of a hot-side ESP assumed in the EPA Control Cost Manual. Therefore, the equations in the EPA Control Cost Manual cannot be used for estimating either of the hypothetical application of SCR configurations for which NDDH has requested economic analyses. Thus it was necessary to prepare independent site-specific cost estimates.

The site-specific control costs estimated for application of hypothetical tail-end and low-dust SCR alternatives to MRYS Unit 2 are significantly higher than the EPA's cost-effectiveness analysis for conventional SCR technologies included in the technical support document issued with the final Regional Haze Regulations and BART Guidelines[8]. Low-dust and tail end SCR technologies should be excluded from consideration for NO_X control at MRYS due to unacceptably high average and incremental cost per ton of pollutant removal based on the supplemental analysis provided herein. The October 2006 NO_X BACT Analysis Study report, and additional subsequent arguments included in responses to comments by the EPA, Department of Justice (DOJ), NDDH, and other parties[9], also present reasons for technical infeasibility of all SCR technologies considered for application at MRYS not included in this supplemental analysis report. In addition, the fact that catalyst vendors will not guarantee catalyst life on such SCR technologies without successful results from extensive pilot slipstream testing bolsters the previous submitted arguments of technical infeasibility of these NO_X control alternatives at MRYS.

4.0.1 ADDITIONAL NOx CONTROLS

The inclusion of hypothetical emissions control alternatives employing tail-end and low-dust SCR technologies in this supplemental NO_X BACT Analysis Study report does not constitute agreement by

---

[7] See Reference number 10, Section 4.2, Chapter 2, page 2-41, October 2000.
[8] See Reference number 4, June, 2005.
[9] Responses submitted by Minnkota in 2007-2009.

Minnkota or Square Butte that it is technically feasible to install these technologies on Unit 2 at Milton R. Young Station. The rationale for rejection of all forms of SCR technology in this specific case, based on an interpretation of the EPA's Draft New Source Review Workshop Manual[10], has previously been submitted to the North Dakota Department of Health[11] and is not repeated herein. Nevertheless, this supplemental NO_X BACT Analysis Study report has been completed based on the *hypothetical assumption* that these two technologies pass the test for technical feasibility. The development of NO_X emissions control alternatives involving hypothetical application of technologies such as low-dust and tail end SCR systems at MRYS is based on preliminary plant layout design concepts that require pilot-scale slipstream SCR testing and more detailed equipment design for confirmation that all technical infeasibility issues previously raised have been, or can be, satisfactorily resolved. This supplemental analysis includes estimated capital costs and operating and maintenance (O&M) costs for four variations of alternatives involving hypothetical applications of tail-end and low-dust SCR technologies. Cost effectiveness for each hypothetically-applied SCR control technology case was plotted with previously-analyzed feasible control alternatives.

For the techniques and technologies considered for determining MRYS Unit 2 NO_X control cost-effectiveness, estimates were produced for predicted NO_X reductions that represent long-term expectations of the reduction techniques and technologies being presented in the technical analysis. Each evaluated alternative was tabulated and graphed.

It should be noted that as of October 2006, when the initial BACT Analysis Study report was completed, MRYS Unit 2 did not employ combustion-related or post-combustion NO_X emission reduction technology. However, the installation of an advanced form of a separated overfire air system (ASOFA), designed specifically for this boiler, was implemented for operation starting prior to December 31, 2007. A summary of the available alternate NO_X emission control technologies is discussed below.

4.1 RANK OF NO_X CONTROL OPTIONS BY EFFECTIVENESS

The first step[12] in this supplemental "top-down" BACT evaluation is to determine the expected control effectiveness of the hypothetical application of tail end and low-dust SCR technology alternatives, so that they may be compared and ranked relative to the technically-feasible NO_X control techniques and

---

[10] Ibid Reference number 3, October 1990.
[11] See Reference number 5, November 2007.
[12] Step 3 per the NSR Manual, Ibid Reference 2, October 1990.

technologies included from the initial NO_X BACT Analysis Study report. To do this, we start with the basis for determining the NOx emissions control effectiveness, which is the historic baseline emissions expressed in pounds per million Btu of heat input from the five-year lookback period.

Unit 2 boiler's baseline pre-control emissions at Milton R. Young Station are based upon the same highest rolling 12-month average unit emission rate (lb/mmBtu) and corresponding highest rolling 12-month average gross heat input rate (mmBtu/hr) that were reported in 2001-2005:

- MRYS Unit 2's highest 12-month NO_X mass emissions averaged 0.786 lb/mmBtu at a corresponding average unit heat input rate of 4,885 mmBtu/hr and unit gross electrical output of 440 MW_g.
- During this lookback time period, Unit 2 at Milton R. Young Station was typically operated in a base-loaded manner.

4.1.1 ESTIMATING CONTROL-EFFECTIVENESS OF NO_X EMISSIONS CONTROL OPTIONS

The estimated emission control performance for NO_X control techniques and technologies included from the initial NO_X BACT Analysis Study report is assumed to be the same as previously stated in Table 3-7[13]. The expected control effectiveness of the hypothetical application of tail end and low-dust SCR technology alternatives was added to the listing of highest-performing NO_X control alternatives remaining in consideration following the initial technical infeasibility determinations. These alternatives are ranked in declining order of expected emission reduction. These combined control options refer to "advanced" separated overfire air (ASOFA), and include the expected reduction from operating with modestly air-staged cyclone furnaces and relocated lignite drying system vent ports as applied to this Milton R. Young cyclone boiler without incurring potential significant negative impacts of this technique. This level of expected NO_X reduction from ASOFA operation is approximately thirty eight percent below the pre-control baseline emissions rate of 0.786 lb/mmBtu.

Alt. Label[1]	NO_X Control Alternative	Emission Rate (lb/mmBtu)	Control Percentage[2]
T2	Hypothetical Tail-End SCR w/ ASOFA – Scenario A[3]	0.049	93.8[4]
T1	Hypothetical Tail-End SCR w/ ASOFA – Scenario B[3]	0.049	93.8[4]
L2	Hypothetical Low-Dust SCR w/ ASOFA – Scenario A[3]	0.049	93.8[4]
L1	Hypothetical Low-Dust SCR w/ ASOFA – Scenario B[3]	0.049	93.8[4]
E	SNCR (using urea) w/ ASOFA	0.330	58.0
D	Gas Reburn with ASOFA	0.350	55.4
C	Lignite Reburn w/ ASOFA	0.360	54.2
B	Fuel Lean Gas Reburn with ASOFA	0.432	45.0
A	Advanced Separated Overfire Air (ASOFA)	0.489	37.7
-	Baseline	0.786	-

(1) - Alternative designation assigned from highest to lowest unit NOx emission rate.

(2) - Control percentages are relative to an average pre-control emission baseline of 0.786 lb/mmBtu based on annual operation at highest pre-control 12-month rolling NOx summation mass emissions divided by the 12-month heat input summation.

(3) - The inclusion of tail-end and low-dust SCR technologies in this table does not constitute agreement that it is technically feasible to install these technologies on Unit 2 at Milton R. Young Station. The emission rate shown for a hypothetically-applied SCR system is based on assumptions that known or expected reasons for technical infeasibility for installation of the SCR equipment on this boiler are solvable. SCR technology is considered technically infeasible by Minnkota for application at MRYS per the October 2006 NOx BACT Analysis Study report and subsequent submittals in response to comments by the NDDH, EPA, DOJ and other parties, so this information for the hypothetical application of SCR alternatives is included for comparative purposes only. See Section 4.2.1.2.1 for details of Scenario A and Scenario B that assumes replacement of SCR catalyst after a specified number of hours of unit operation.

(4) - The stated overall control percentage includes the anticipated long-term emission reduction of 90% design removal from a baseline of 0.49 lb/mmBtu resulting from an advanced separated overfire air system, with air-staged low-NO_X cyclone combustion. Without a separated overfire air system operation or any other technique employed, the assumed emission rate for hypothetically-applied SCR alternatives would be 0.079 lb/mmBtu, for an overall reduction of 90 percent from a baseline of 0.786 lb/mmBtu.

All hypothetical applications of tail-end and low-dust SCR technology alternatives were assumed to achieve a NO_X emission level of 0.049 lb/mmBtu, which is approximately a 90% reduction from a 0.49 lb/mmBtu level representing ASOFA when operating modestly air-staged cyclone furnaces with suitable combustion controls.

Hourly mass emission rates for the baseline pre-control condition were calculated by multiplying the unit emission rate (lb/mmBtu) by the average hourly gross heat input rate (mmBtu/hr), both calculated from Unit 2’s highest 12-month NO_X mass emissions and heat inputs during the 5-year lookback period.

Equivalent annual NO_X emissions (tons) were calculated by multiplying the 12-month summation for unit operating hours during the same period as the highest NO_X emissions by the 12-month average mass emission rate (lb/hr) and dividing by 2000 lb/ton.

The annual tons for the control options were calculated by multiplying the alternative's equivalent average annual hourly mass emission rate (lb/h) by the equivalent annual unit operating hours [8,760 h/yr maximum possible operating time, adjusted by an annual uptime (availability) factor]. Scheduled and unplanned maintenance outages are expected to occur due to each hypothetically-applied SCR system. Catalyst cleaning and replacement events have been estimated, with two frequencies showing a range of possible results. Due to the variability and possible severity of fouling characteristics of gaseous and aerosol particulate emissions generated by cyclone combustion of lignite supplied from the Center mine, and the dependency of the fouling within the hypothetically-applied SCR systems on sodium, potassium, sulfur, and ammonia slip emission levels, conditions may occur during operation of the hypothetically-SCR systems that exceed the ability to adjust operational practices sufficiently to avoid forced outages to remove the deposits or prevent significant catalyst deactivation. Table C.4-1 in Section 4.2.1.2.1 includes estimated unit availability and corresponding operating time and outage time due to the four hypothetical applications of SCR technology cases, along with the ASOFA and baseline numbers from the referenced Appendix C3 of the initial NO_X BACT Analysis Study report[14]. Based on these calculations, the estimated annual emissions for M.R. Young Station Unit 2 and the emission reduction corresponding to each technology alternative are shown in Table 4-2.

---

[14] Ibid Reference number 3, October 2006, pages C3-1 through page C3-11.

TABLE 4-2 – Expected Annual NO_X Control Performance for MRY Station Unit 2 Alternatives

Alt. Label(1)	NOx Control Alternative	EMISSIONS				NOx Removal Efficiency(5) %
		Emission Rate lb/mmBtu	Hourly Emission(2) lbs/hr	Annual Emission(3) tons/yr	Emission Reduction(4) tons/yr	
T2	Hypothetical Tail End SCR w/ ASOFA – Scenario A(6)	0.049	239	936	14,857	93.8(7)
T1	Hypothetical Tail End SCR w/ ASOFA – Scenario B(6)	0.049	239	813	14,980	93.8(7)
L2	Hypothetical Low-Dust SCR w/ ASOFA – Scenario A(6)	0.049	239	931	14,862	93.8(7)
L1	Hypothetical Low-Dust SCR w/ ASOFA – Scenario B(6)	0.049	239	813	14,980	93.8(7)
E	SNCR (using urea) w/ ASOFA	0.330	1,612	6,421	9,372	58.0
D	Gas Reburn w/ ASOFA	0.350	1,710	6,882	8,910	55.4
C	Lignite Reburn w/ ASOFA	0.360	1,759	6,964	8,829	54.2
B	Fuel Lean Gas Reburn w/ ASOFA	0.432	2,110	8,490	7,303	45.0
A	Advanced Separated Overfire Air (ASOFA)	0.489	2,391	9,621	6,172	37.7
-	Baseline	0.786	3,839	15,793	0	-

(1) - Alternative label has been assigned from highest to lowest unit NOx emission rate.

(2) - Hourly NO_X emission estimates (lb/hr) were calculated based upon average annual unit emission rate (lb/mmBtu) x 4,885 mmBtu/hr heat input.

(3) - Estimated annual emission tons assume an annual unit availability factor specific to each alternative; 93.9% was assumed for the baseline case. See Appendix C3 of the October 2006 NO_X BACT Analysis Study report. Hypothetically-applied tail end SCR case T2 assumes an annual unit availability factor of 89.5% (approx. 7,842 operating hours per year) and case T1 assumes an annual unit availability factor of 77.8% (approx. 6,813 operating hours per year. Hypothetically-applied low-dust SCR case L2 assumes an annual unit availability factor of 89.0% (approx. 7,801 operating hours per year) and case L1 assumes an annual unit availability factor of 77.8% (approx. 6,813 operating hours per year).

(4) - Estimated annual tons of emission reduction is the difference between annual baseline tons and each alternative's annual emissions (tons).

(5) - Estimated NO_X control level percentage reductions relative to 0.786 lb/mmBtu emission baseline at 4,885 mmBtu/hr MCR heat input.

(6) - The inclusion of tail-end and low-dust SCR technologies in this table does not constitute agreement that it is technically feasible to install these technologies on Unit 2 at Milton R. Young Station. The emission rate shown for a hypothetically-applied SCR system is based on assumptions that known or expected reasons for technical infeasibility for installation and operation and maintenance of the SCR equipment on this boiler are solvable. SCR technology is considered technically infeasible by Minnkota for application at MRYS per the October 2006 NO_X BACT Analysis Study report and subsequent submittals in response to comments by the NDDH, EPA, DOJ, and other parties, so this information for the hypothetical application of SCR alternatives is included for comparative purposes only. See Section 4.2.1.2.1 for details of Scenario A and Scenario B that assume replacement of SCR catalyst after a specified number of hours of unit operation.

(7) - The stated overall control percentage includes the anticipated long-term emission reduction of 90% design removal from a baseline of 0.49 lb/mmBtu resulting from an advanced separated overfire air system, with air-staged low-NO_X cyclone combustion. Without a separated overfire air system operation or any other technique employed, the assumed emission rate for hypothetically-applied SCR alternatives would be 0.079 lb/mmBtu, for an overall reduction of 90 percent from a baseline of 0.786 lb/mmBtu.

4.2 NO_X CONTROLS ANALYSIS AND IMPACTS EVALUATION

The next step[15] of this supplemental "top-down" BACT analysis is to evaluate the impacts of the hypothetical application of SCR alternatives' NO_X emission controls. Energy, economic, and environmental impacts are to be considered in the control technology evaluation. The purpose of the evaluation is to determine if there are any energy, economic or environmental impacts that would eliminate the top control technologies from consideration.

This evaluation of the effectiveness of the hypothetically-applied SCR alternatives, as well as that of the other control technologies previously considered technically feasible, was performed prospectively, i.e., assuming that none of the control technologies has been implemented. This approach assumes that the hypothetical application of SCR technology cases are considered to have been added to the previous NO_X BACT Analysis Study report submitted in October, 2006. The actual costs incurred and performance achieved for an installed advanced separated overfire air system, or firm price equipment quotes with performance guarantees for SNCR alternatives, that have been determined after the submittal of the 2006 NO_X BACT Analysis Study report, have not been used to adjust the control effectiveness or cost impacts of the previously analyzed control alternatives. The approach taken in this supplemental analysis uses installed capital costs estimated in calendar year 2009 escalated to project completion forecast in 2017 adjusted to calendar year 2006 basis for the hypothetically-applied tail end SCR and low-dust SCR technology cases that have been added to the list of alternatives previously evaluated.

4.2.1 NO_X CONTROL ECONOMIC IMPACTS FOR MRY STATION UNIT 2

An evaluation was performed to determine the various cost impacts of installing previously-analyzed feasible NO_X control alternatives and hypothetical application of low-dust and tail end SCR technologies on Milton R. Young Unit 2. This evaluation includes estimated:

- Capital costs;
- Fixed and variable operating and maintenance costs; and
- Levelized total annual costs

to engineer, design, procure, construct, install, startup, test, and place into commercial operation the particular control technology. The results of this evaluation are summarized in Tables 4-3 through 4-11.

---

[15] Step 4 per the NSR Manual, Ibid Reference 2, October 1990.

4.2.1.1 CAPITAL COST ESTIMATES FOR NO_X CONTROL ALTERNATIVES

The range of estimated capital costs to implement some of the various NO_X control technologies were derived from unit output capital cost factors ($/kW) published in technical papers discussing those control technologies. For MRY Station Unit 2, for the cases involving the use of advanced separated overfire air and SNCR alternatives, preliminary project cost estimates using vendor budgetary cost information were developed and used in place of, or to adjust, the published unit output cost factors. A discussion of the reburn alternatives' estimated capital costs was included in the 2006 NO_X BACT Analysis Study report and has not been repeated here. These cost estimates were considered to be study grade, which is + or – 30% accuracy.

For the hypothetical application of low-dust and tail end SCR alternatives at MRYS, there is no available information on recently-completed similar projects on coal-fired powerplants in the United States that could be used, with adjustments, to properly represent total installed costs that could be expected for MRYS Unit 2. For these alternatives, site-specific detailed preliminary (conceptual) designs were developed and budgetary cost information for major equipment was obtained for the development of the estimated installed capital cost.

The unit nameplate output capacity (gross electrical output in megawatts) assumed for the installed capital cost estimate basis of the NO_X control technologies evaluated was 477 MW_g for MRY Station Unit 2[16].

A review of the unit capital cost factor range and single point factors applicable to MRY Station Unit 2 NO_X control technologies are presented in Tables 4-3SA and 4-3SF. Note that the capital cost estimates for the hypothetical application of SCR alternatives were developed separately based on two different assumptions. In one case it was assumed that all costs for the hypothetically-applied Unit 2 SCR (tail end or low-dust) system would be accounted for as if the SCR equipment were being provided for Unit 2 only. This is referred to as the "stand alone" (SA) case, and all tables showing those costs are identified with that suffix. In the other case, it was assumed that the retrofit of hypothetically-applied SCR systems was being done for both Unit 1 and Unit 2, and there are some components that could be shared between the two units. This is referred to as the "shared facilities" (SF) case, and all tables showing those costs are identified with that suffix.

---

[16] Ibid Reference number 4, June 2005, Excel Spreadsheet OAR-2002-0076-0446, page 390.

Per the EPA's NSR Manual, a BACT analysis is done on a "case-by-case basis"[17]. The "stand alone" estimated total project capital costs for the hypothetical application of SCR alternatives reflect the economic impacts incurred as a result of implementing such technologies on each individual unit at MRYS independent of what may be determined or assumed for other units at this facility or similar units at other facilities. The "shared facilities" estimated total project capital costs for the hypothetical application of SCR alternatives do not account for all economic impacts borne strictly by the unit subject to the analysis, and as such, are subsidized by the unit(s) involved with the shared facilities. In this "shared facilities" approach, a BACT would be performed more in the manner of a "case-within-a-case" instead of on a "case-by-case" basis. Additionally, BACT is not to be applied on a facility basis. Units having different characteristics, (size, etc.) may have different technologies as BACT. Therefore, each unit should be treated as a separate "stand alone" case. Although the authors believe the "stand alone "case is the proper approach to use, information for both cases has been provided.

TABLE 4-3SA – Unit Capital Cost Factors of NO_X Control Alternatives for MRY Station Unit 2 - Stand Alone SCR Projects

Alt. Label(1)	**NO_X Control Alternative**	**Range(2) ($/kW)**	**Single Point Unit Capital Cost Factor(3), ($/kW) MRYS Unit 2**
T2	Hypothetical Tail End SCR w/ ASOFA – Scenario A(4)	(4)	714(4),(5)

infeasibility for installation of the SCR equipment on this boiler are solvable. SCR technology is considered technically infeasible by Minnkota for application at MRYS per the October 2006 NO_X BACT Analysis Study report and subsequent submittals in response to comments by the NDDH, EPA, DOJ and other parties, so this information for the hypothetical application of SCR alternatives is included for comparative purposes only. See Section 4.2.1.2.1 for details of Scenario A and Scenario B that assumes replacement of SCR catalyst after a specified number of hours of unit operation. Due to the site-specific nature of factors influencing cost, no comparable cost data ranges for these technologies exist in the literature. A cost range for conventional high-dust SCR technology published in the 2005 EPA Report "Multipollutant Emission Control Technology Options for Coal-fired Power Plants", EPA-600/R-05/034[18] was $55 to $150/kW. Single point unit capital cost factors were derived from Burns & McDonnell internal database and cost estimates prepared specifically for MRYS Unit 2 in 2017 dollars converted to 2006$ as described in the text.

(5) - The single point unit capital cost factor shown for the "advanced" version of SOFA derived from Burns & McDonnell internal database and cost estimate for North Dakota lignite-fired cyclone boilers.

(6) - Estimated capital cost for SNCR point estimate and FLGR point estimate derived from December 2004 budgetary proposal by Fuel Tech. The unit capital cost factor range for FLGR applications on boilers without an existing a high-pressure natural gas supply was not found in available technical literature. See Appendix C2 of the October 2006 NO_X BACT Analysis Study report for details[19].

(7) - NESCAUM 2005 Technical Paper[20]; reburn alternatives on page 2-22, overfire air on page 2-23; posted at their website. See technical references in Appendix A1 of the October 2006 NO_X BACT Analysis Study report for details.

(8) - The single point unit capital cost factor shown for a conventional or fuel-lean gas reburn system includes the estimated capital cost to install a high-pressure natural gas supply pipeline (31.4 $/kW or 15.7 $/kW, respectively), and that both MRYS boilers share the capital cost in proportion to their respective rated MW gross output capacities.

(9) - The single point unit capital cost factor shown for a lignite reburn system is highly site-specific, and assumes that new pulverizers and building enclosures are required. The general cost range for pulverized coal-fired boilers is included in the NESCAUM 2005 Technical Paper; for cyclone boilers is included in the 2005 WRAP Draft Report[21], posted at their website. The single point unit capital cost factor for this alternative for increased PM collection capacity included in lignite reburn option is 75.5 $/kW. See technical references in Appendix A1 of the October 2006 BACT Analysis report for details.

See Appendix C2 of the October 2006 NO_X BACT Analysis Study report for details[23].

(7) - NESCAUM 2005 Technical Paper[24]; reburn alternatives on page 2-22, overfire air on page 2-23; posted at their website. See technical references in Appendix A1 of the October 2006 NO_X BACT Analysis Study report for details.

(8) - The single point unit capital cost factor shown for a conventional or fuel-lean gas reburn system includes the estimated capital cost to install a high-pressure natural gas supply pipeline (31.4 $/kW or 15.7 $/kW, respectively), and that both MRYS boilers share the capital cost in proportion to their respective rated MW gross output capacities.

(9) - The single point unit capital cost factor shown for a lignite reburn system is highly site-specific, and assumes that new pulverizers and building enclosures are required. The general cost range for pulverized coal-fired boilers is included in the NESCAUM 2005 Technical Paper; for cyclone boilers is included in the 2005 WRAP Draft Report[25], posted at their website. The single point unit capital cost factor for this alternative for increased PM collection capacity included in lignite reburn option is 75.5 $/kW. See technical references in Appendix A1 of the October 2006 BACT Analysis report for details.

4.2.1.1.1 CAPITAL COST ESTIMATES FOR HYPOTHETICAL APPLICATION OF SCR NO_X CONTROL ALTERNATIVES

There is no available information on recently-completed similar tail-end or low-dust SCR projects on coal-fired powerplants in the United States that could be used, with adjustments, to represent total installed costs that could be expected for MRYS Unit 2. Site-specific needs and challenges identified for applying tail end and low-dust SCR technologies to Milton R. Young Station Unit 2 significantly influence the capital cost estimate for variations of these hypothetical alternatives. Furthermore, the "EPA Air Pollution Control Cost Manual" is not applicable for use in estimating control equipment costs for these hypothetical applications of SCR technology cases, as the EPA Control Cost Manual states:

---

[22] See Reference number 6, March 2005, page 3-63.
[23] See Reference number 3, October 2006, pages C2-3 and C2-7.
[24] See Reference number 7, March 2005.
[25] See Reference number 8, April 2005, page 3-9.

> "The costs for the tail-end arrangement, however, cannot be estimated from this report because they are significantly higher than the high-dust SCR systems due to flue gas reheating requirements."[26]

This requirement for flue gas reheating also applies to the hypothetical application of low-dust SCR to MRYS, due to the cold-side arrangement (downstream of the electrostatic precipitator) instead of a hot-side ESP assumed in the EPA Control Cost Manual. Therefore, the equations in the EPA Control Cost Manual cannot be used for estimating either of the hypothetical SCR configurations for which NDDH has requested economic analyses. Thus it was necessary to prepare independent site-specific cost estimates.

The installed capital costs for hypothetical application of tail end and low-dust SCR alternatives were estimated by Burns & McDonnell with inputs from an SCR system supplier with recent design experience involving these SCR configurations, equipment suppliers, and catalyst suppliers with significant European project experience in such technology. Both hypothetically-applied low-dust and tail end SCR designs for MRYS Unit 2 assume two reactor / gas reheat systems installed in parallel, each connecting to one of the two existing wet lime flue gas desulfurization absorbers also arranged in parallel configuration. Each alternative includes flue gas reheat equipment that is typical for these applications but not required for conventional high-dust/hot side SCRs. The estimated flue gas volume at a gross boiler heat input and oxygen content corresponding to unit gross nameplate output capacity determined the size of the two hypothetically-applied SCR reactors for these cases. Structures, foundations, ductwork, balance of plant equipment and materials were quantified and included with the hypothetically-applied SCR equipment, which were factored for installation costs. Escalation of project costs, including equipment, materials, engineering and labor costs, is included, along with interest during construction, due to the expected project execution duration being significantly longer than for the other alternatives. Price and scope contingencies were included to account for the uncertainties that the current preliminary design scope and pricing fully reflects what would be necessary to complete implementation of these hypothetically-applied alternatives. Total project costs were considered to be a future value from a financial perspective, which were returned to a 2009 calendar year basis using a present value factor at the 2.5% per year annual discount rate previously assumed in the 2006 NO_X BACT Analysis Study report. A ratio of regional construction cost indices for public utility construction costs between 2006 and 2009 was used to adjust the 2009 total estimated project costs to a 2006 calendar year basis for each of the hypothetically-applied SCR alternatives.

---

[26] See Reference number 10, Section 4.2, Chapter 2, page 2-41, October 2000.

The estimated installed and levelized annual capital costs for the hypothetically-applied SCR systems and previously-analyzed highest-performing form of the various feasible NO_X emission reduction technologies evaluated for cost-effectiveness are shown in Table 4-4SA and Table 4-4SF. These technologies are listed in order of control effectiveness, with the highest ranked option at the top.

TABLE 4-4SA – Estimated Capital Costs for NO_X Control Alternatives - MRY Station Unit 2 - Stand Alone SCR Projects

Alt. Label(1)	**NOx Control Alternative**	**Installed Capital Cost(2) $1,000**	**Annualized Capital Cost(3) $1,000**
T2	Hypothetical Tail End SCR w/ ASOFA – Scenario A(4)	340,733(4)	29,707(4)
T1	Hypothetical Tail End SCR w/ ASOFA – Scenario B(4)	340,733(4)	29,707(4)
L2	Hypothetical Low-Dust SCR w/ ASOFA – Scenario A(4)	270,785(4)	23,608(4)
L1	Hypothetical Low-Dust SCR w/ ASOFA – Scenario B(4)	270,785(4)	23,608(4)

A	Advanced SOFA (ASOFA)	10,008	873
	Baseline	0	0

(1) - Alternative label has been assigned from highest to lowest unit NOx emission rate.

(2) - Installed capital cost is estimated for determination of total capital cost for a particular technology or combination, assuming 477 MWg unit capacity rating. All cost figures in 2006 dollars. See Table 4-5SA for presentation of installed capital costs determined for hypothetical application of SCR alternatives.

(3) - Annualized capital cost = Installed capital cost x 0.08718 annualized capital cost factor.

(4) - The inclusion of tail end and low-dust SCR technologies in this table does not constitute agreement that it is technically feasible to install these technologies on Unit 2 at Milton R. Young Station. The installed capital cost shown for a hypothetically-applied SCR system is based on assumptions that known or expected reasons for technical infeasibility for installation of the SCR equipment on this boiler are solvable. Costs are derived from Burns & McDonnell internal database and cost estimates prepared specifically for MRYS Unit 2 in 2017 dollars converted to 2006$ as described in the text. SCR technology is considered technically infeasible by Minnkota for application at MRYS per the October 2006 NO_X BACT Analysis Study report and subsequent submittals in response to comments by the NDDH, EPA, DOJ and other parties, so this information for the hypothetical application of SCR alternatives is included for comparative purposes only. See Section 4.2.1.2.1 for details of Scenario A and Scenario B that assumes replacement of SCR catalyst after a specified number of hours of unit operation.

(5) - Costs for gas reburn options include high-pressure natural gas supply pipeline installed capital cost of $14,988,000 for CGR and $7,494,000 for FLGR; and annualized capital cost of $1,307,000/yr for CGR and $653,000 for FLGR. See footnote number 8 under Table 4-3SA.

(6) - Costs for increased PM collection capacity included in lignite reburn option are $36,013,000 for installed capital cost, and $3,140,000/yr annualized capital cost.

TABLE 4-4SF – Estimated Capital Costs for NO_X Control Alternatives - MRY Station Unit 2 – Shared Facilities SCR Projects

Alt. Label(1)	NOx Control Alternative	Installed Capital Cost(2) $1,000	Annualized Capital Cost(3) $1,000

(1) - Alternative label has been assigned from highest to lowest unit NOx emission rate.
(2) - Installed capital cost is estimated for determination of total capital cost for a particular technology or combination, assuming 477 MWg unit capacity rating. All cost figures in 2006 dollars. See Table 4-5SF for presentation of installed capital costs determined for hypothetical application of SCR alternatives.
(3) - Annualized capital cost = Installed capital cost x 0.08718 annualized capital cost factor.
(4) - The inclusion of tail end and low-dust SCR technologies in this table does not constitute agreement that it is technically feasible to install these technologies on Unit 2 at Milton R. Young Station. The installed capital cost shown for a hypothetically-applied SCR system is based on assumptions that known or expected reasons for technical infeasibility for installation of the SCR equipment on this boiler are solvable. Costs are derived from Burns & McDonnell internal database and cost estimates prepared specifically for MRYS Unit 2 in 2017 dollars converted to 2006$ as described in the text. SCR technology is considered technically infeasible by Minnkota for application at MRYS per the October 2006 NO_X BACT Analysis Study report and subsequent submittals in response to comments by the NDDH, EPA, DOJ and other parties, so this information for the hypothetical application of SCR alternatives is included for comparative purposes only. See Section 4.2.1.2.1 for details of Scenario A and Scenario B that assumes replacement of SCR catalyst after a specified number of hours of unit operation.
(5) - Costs for gas reburn options include high-pressure natural gas supply pipeline installed capital cost of $14,988,000 for CGR and $7,494,000 for FLGR; and annualized capital cost of $1,307,000/yr for CGR and $653,000 for FLGR. See footnote number 8 under Table 4-3SF.
(6) - Costs for increased PM collection capacity included in lignite reburn option are $36,013,000 for installed capital cost, and $3,140,000/yr annualized capital cost.

The Total Project Costs estimated for tail end and low-dust SCR technologies hypothetically-applied to MRYS Unit 2 are shown in Table 4-5SA and Table 4-5SF in 2017, 2009, and 2006 dollars.

The estimated installed capital costs for the hypothetical application of tail end or low-dust SCR system retrofits on MRYS Unit 2 include the following equipment and components:

- Two SCR reactors utilizing a "3 +1" arrangement of catalyst layers, in which three layers of catalyst are initially installed, and space for installation of a fourth layer is provided.
- Sootblowers for each catalyst layer to maintain cleanliness of catalyst
- Flue gas reheat equipment that is typical for these applications but not required for conventional high-dust/hot side SCRs. This reheat equipment includes rotary regenerative heat exchangers (gas-to-gas heaters [GGH]) and natural gas-fired duct burners.
- Underground high-pressure natural gas supply pipeline and pressure regulators and metering equipment
- Hot air recirculation and heating equipment to maintain catalyst in a warm and dry condition during standby periods
- Induced draft booster fan and dampers
- Interconnecting ductwork
- SCR bypass duct and dampers (used during times the boiler is off-line)
- Storage tanks, building, and equipment for unloading and preparation of liquid urea solution
- Circulation pumps and piping for urea solution
- Urea-to-ammonia thermal conversion with urea conversion, metering, atomization, and injection equipment
- Ammonia gas dilution/combustion air fans and burners for natural gas-firing to decompose the urea solution to ammonia
- Service and sootblowing air compressors with dryers
- Electrical motor control centers
- Controls and instrumentation
- Reinforced concrete foundations
- Active coal yard storage modifications to regain lost live capacity and handling equipment due to space consumed by the SCR reactor structures
- Installation labor, materials, and management

Addition of new electrical loads to the existing plant facilities will be required for the reagent system and new induced draft booster fan power consumption. Based on recent plant electrical distribution equipment installations, additional plant auxiliary electrical power will be available for powering the new hypothetically-applied SCR equipment. Confirmation of these concepts and cost estimates prior to any subsequent plans for implementation requires successful completion of extensive pilot-scale slipstream

testing, and more detailed plant layout and equipment design than has been performed as part of this supplemental update to the October 2006 NO_X BACT Analysis Study report.

The capital cost estimated individually for an ASOFA system retrofit on MRYS Unit 2 as previously described in the initial NO_X BACT Analysis Study report was simply arithmetically added to the hypothetical application of SCR alternatives' capital cost estimates.

4.2.1.2 O&M COST ESTIMATES FOR NO_X CONTROL ALTERNATIVES

Operational costs to implement the hypothetical application of SCR alternatives and previously-analyzed feasible NO_X control alternatives for Milton R. Young Unit 2 were estimated using preliminary conceptual designs and budgetary vendor quotes in place of, or to adjust, the OAQPS cost factors established in the EPA's Air Pollution Control Cost Manual (OAQPS) for SNCR[27] and SCR[28], and using other costs from

---

[27] See Reference number 9, October 2000.

[28] See Reference number 10, October 2000.

published technical papers discussing those control technologies. Maintenance costs were estimated as percentages of installed capital costs, with additional catalyst replacement costs using budgetary vendor quotes based on preliminary conceptual designs and expected design life.

Fixed and variable operating and maintenance costs considered and included in each NO_X control technology's annual O&M costs are estimates of:

- Auxiliary electrical power consumption (megawatt-hours) and incremental purchased power unit costs for operating the additional control equipment;
- Natural gas consumption and unit cost for hypothetical application of SCR alternatives' flue gas reheating and urea-to-ammonia thermal conversion systems and feasible fuel reburn alternatives;
- Reagent consumption and reagent unit cost for hypothetical application of SCR alternatives and feasible SNCR alternatives;
- Reagent dilution water consumption and unit cost for feasible SNCR alternatives.
- Catalyst removal and replacement for hypothetical application of SCR alternatives.
- Increases or savings in auxiliary electrical power consumption for changes in coal preparation equipment and loading, primarily for fuel reburn cases;
- General operating labor, plus maintenance labor and materials devoted to the additional emission control equipment and its impact on existing boiler and plant equipment;
- Costs for purchase of replacement electrical power expected to result from loss of unit availability, i.e., outages attributable to the control option which reduce annual net electrical generation available for distribution.

For economic evaluation purposes, a 12-month rolling average running plant capacity factor of 95.2 percent (based on a historic (demonstrated) sustainable unit output capacity of 462 MW_g) combined with a 12-month rolling average availability (uptime) of 8,229 operating hours (93.9 percent of 8760 hours per year) resulting in an equivalent annual average unit capacity factor of 89.5% was assumed for Unit 2's pre-control baseline annual operation. A 12-month rolling average heat input rate of 4,885 mmBtu/hr and a 12-month rolling average NO_X emission rate of 0.786 lb/mmBtu from pre-control maximum rolling 12 month summation of nitrogen oxides mass emissions were assumed for calculating equivalent annual average control and cost-effectiveness for MRY Station Unit 2.

Tables 4-6SA and 4-6SF show the estimated annual operating and maintenance costs and levelized annual O&M cost values for the hypothetically-applied SCR alternative cases and the highest-performing form of previously-evaluated feasible NO_X emission reduction technologies. These are listed in order of control effectiveness, with the highest ranked options at the top. The cost methodology summarized in Appendix C3 of the 2006 NOx BACT Analysis Study report provides more details for the levelized annual O&M cost calculations and cost factors for the previously-analyzed feasible NO_X control alternatives[29].

TABLE 4-6SA – Estimated O&M Costs for NO_X Control Alternatives - MRY Station Unit 2 - Stand Alone SCR Projects

Alt. Label(1)	NOx Control Alternative	Annual O&M Cost(2) $1,000	Levelized Annual O&M Cost(2),(3) $1,000
T2	Hypothetical Tail End SCR w/ ASOFA – Scenario A(4)	31,512	39,350
T1	Hypothetical Tail End SCR w/ ASOFA – Scenario B(4)	55,345	69,111
L2	Hypothetical Low-Dust SCR w/ ASOFA – Scenario A(4)	29,048	36,273

4.2.1.2.1 O&M COST ESTIMATES FOR HYPOTHETICAL APPLICATION OF SCR NO_X CONTROL ALTERNATIVES

The hypothetical application of tail-end and low-dust SCR w/ ASOFA alternatives will involve significantly higher operating costs compared with the existing operation of MRYS Unit 2. The system uses an amine reagent in the form of concentrated aqueous urea solution, which is thermally converted to gaseous ammonia, carbon dioxide, and water vapor. The estimated unit cost of this urea was assumed to average $379/ton (delivered to the plant site via truck-tanker trailers; unit pricing based on 50% concentration as established for the 2006 NO_X BACT Analysis Study report). Consumption of urea converted to ammonia reagent was based upon recent equipment vendor budgetary proposals and SCR consultant inputs.

For the hypothetically-applied SCR cases, using the existing induced draft fans is not expected to significantly change the overall fan horsepower demand on those fans' electric motors. There will be new plant electrical power demand due to new induced draft booster fans required to overcome the estimated additional flue gas pressure drop resulting from reactor, ductwork, and gas-to-gas heat exchanger equipment assumed for the hypothetically-applied SCR systems. The additional auxiliary electric power demand for the hypothetically-applied tail end SCR systems was calculated to be 14.9 MW, using estimated annual average electrical loads of the booster fan, direct flue gas reheat burner combustion air fans, urea-to-ammonia conversion dilution/combustion air fans, and SCR sootblower and service air compressor equipment based on preliminary equipment vendor budgetary proposals developed from Burns & McDonnell ductwork sizing and designs. Estimated annual average electrical power demands for hypothetically-applied low-dust SCR systems were calculated to be 12.4 MW. Replacement of electrical power resulting from these reductions in net unit electrical output was included as a cost, assuming $35 per megawatt-hour.

Hypothetically-applied tail end and low-dust SCR equipment requiring annual maintenance includes booster fans, gas-to-gas heat exchangers, flue gas reheat duct burners, and compressor equipment. This general annual maintenance cost was estimated as 3 percent of installed capital costs.

To account for the possible range of O & M costs due to catalyst replacement, two variations (Scenario A and Scenario B) were applied. These two scenarios were used for both hypothetical applications of tail-end and low-dust SCR technology alternatives. Each scenario was based on scheduled additions and/or replacement of the exposed catalyst after a certain number of hours of operation, repeated throughout the 20 year operating span considered in the analysis. The current installed unit cost of replacement catalyst assumed for the hypothetical application of full-time tail end or low-dust SCR alternatives is $7,500 per cubic meter in 2006 dollars. The basis for development of the two scenarios is described below.

During preparation of the cost estimate, Burns & McDonnell consulted with two SCR catalyst vendors experienced with biomass-fired boiler SCRs and European coal-fired boilers with low-dust and tail end SCR systems. However, neither of these vendors was willing to guarantee a catalyst replacement schedule for cyclone boilers firing North Dakota lignite without results following successful extensive pilot-scale slipstream testing that confirm the deactivation and fouling rates. According to these catalyst suppliers, there is no SCR operating experience in the world found to be directly comparable to the hypothetically-applied tail end and low-dust SCR cases on North Dakota lignite-fired cyclone boilers being evaluated. Thus they were unable to offer a guaranteed catalyst replacement schedule based on their experience.

Based on information obtained in discussions with the catalyst vendors, the longest catalyst replacement schedule they would both agree upon as an estimated (not guaranteed) value was 16,000 hours. Both vendors indicated that actual experience could result in a shorter replacement cycle, and that the actual guarantee value could not be developed until extensive pilot testing had been completed. This led Burns & McDonnell to develop two hypothetically-applied SCR catalyst replacement scenarios to bracket possible outcomes.

Scenario A assumed a catalyst replacement schedule of 16,000 hours. Specifically for MRYS Unit 2, this scenario is based on the replacement of one catalyst layer in each reactor every 16,000 operating hours.

Scenario B assumed that the fouling of the catalyst would be severe, and that it would be necessary for Minnkota to perform catalyst maintenance at each scheduled boiler cleaning outage. The current schedule of boiler cleaning outages on Unit 2 is four times per year. Therefore, Scenario B for Unit 2 is based on the replacement of one catalyst layer in each reactor at each boiler cleaning outage. This means that each catalyst layer in the four layer SCR reactor is exposed to flue gas during approximately 12 months of operation and then is replaced. By assuming that catalyst management activities would coincide with scheduled boiler cleaning outages, Scenario B provides some minimization of the impact of catalyst replacement on unit operation.

As noted above, it is not known what the actual frequency of catalysts replacement would need to be for a hypothetically-applied tail-end or low dust SCR system operating on a cyclone-fired boiler burning North Dakota lignite, but the two scenarios described above are the catalyst replacement numbers assumed for this comparative economic analysis.

SCR catalyst replacements are additive to the general annual hypothetically-applied low-dust and tail end SCR equipment maintenance. Catalyst replacement costs are based on catalyst vendor quotation of volume of catalyst, estimated to be three layers initially (top, middle-upper and middle-lower) at 256 cubic meters per layer per reactor for two reactors in parallel. A fourth (bottom) layer at 342 cubic meters is expected to be required after initial operation of hypothetically-applied full-time tail end or low-dust SCR alternatives, as part of the catalyst replacement program. Catalyst replacement costs for the hypothetical application of SCR alternatives were estimated for the two different catalyst management scenarios described above.

Annual unit operating time will be reduced as a result of the expected outages and maintenance of the hypothetically-applied SCR equipment, including catalyst cleaning and management practices. Additional outage time of 206 hours per year was estimated to be attributable to the hypothetical application of tail end SCR Scenario A alternative (assuming 16,000 hour catalyst life), and 1,235 hours per year for the Scenario B TESCR case (assuming four layers are replaced every year) over and above the outage time assumed for ASOFA impacts. Additional outage time of 247 hours per year was estimated to be attributable to the hypothetical application of low-dust SCR Scenario A alternative, and 1,235 hours per year for the Scenario B LDSCR case over and above outage time assumed for ASOFA impacts. The expected loss of electrical power generation from these reductions in net output was included as a cost, assuming $35 per megawatt-hour for replacement power.

Table C.4-1 provides the estimated unit availability and corresponding operating time and outage time due to the four hypothetically-applied SCR technology cases, along with the ASOFA and baseline numbers from the referenced Appendix C3 of the initial NO_X BACT Analysis Study report[30].

TABLE C.4-1 – Expected Availability Reductions for MRYS Unit 2 NO_X Controls

Alt.[1]	NOx Control Alternative	Estimated Annual Average Unit Operating Time			
		Unit Availability[2]	Unit Operating Time[3], hrs/yr	Unit Outage Time[4], hrs/yr	Unit Operating Time Reduction[5], hrs/yr
T2	Hypothetical Tail End SCR w/ ASOFA – Scenario A(6)	0.895	7,842	918	387
T1	Hypothetical Tail End SCR w/ ASOFA – Scenario B(6)	0.778	6,813	1,947	1,416
L2	Hypothetical Low-Dust SCR w/ ASOFA – Scenario A(6)	0.890	7,801	959	428
L1	Hypothetical Low-Dust SCR w/ ASOFA – Scenario B(6)	0.778	6,813	1,947	1,416
E	SNCR w/ ASOFA	0.909	7,965	795	264
D	Gas Reburn w/ ASOFA	0.919	8,048	712	181
C	Coal Reburn w/ ASOFA	0.904	7,916	844	313
B	FLGR w/ ASOFA	0.919	8,048	712	181
A	Advanced SOFA (ASOFA)	0.919	8,048	712	181
	Baseline	0.939	8,229	531	0

(1) – Alternative number has been previously assigned from least removal to highest removal percentage.

(2) – 12-month baseline availability is assumed at 93.9 percent. These values reflect estimated amounts of negative reliability impact expected from the implementation of the individual NOx control technology.

(3) – Annual operating time is annual average availability multiplied by 8760 hrs/yr of possible uptime.

(4) – Annual outage time is 8760 hrs/yr possible operating time minus estimated annual operating time.

(5) – Annual operating time reduction resulting from the implementation of the individual NOx control technique is the difference between the baseline and expected annual outage times.

(6) – The inclusion of tail-end and low-dust SCR technologies in this table does not constitute agreement that it is technically feasible to install these technologies on Unit 2 at Milton R. Young Station. The estimated annual unit availability factors shown for hypothetically-applied SCR systems are based on assumptions that known or expected reasons for technical infeasibility for installation and operation and maintenance of the SCR equipment on this boiler are solvable. SCR technology is considered technically infeasible by Minnkota for application at MRYS per the October 2006 NO_X BACT Analysis Study report and subsequent submittals in response to comments by the NDDH, EPA, DOJ and other parties,, so this information for the hypothetical application of SCR alternatives is included for comparative purposes only. See Section 4.2.1.2.1 for details of Scenario A and Scenario B that assume replacement of SCR catalyst after a specified number of hours of unit operation.

Table C.4-2 includes estimated equivalent average annual unit running plant capacity ratios and unit generation reductions due to the four hypothetically-applied SCR cases, along with the ASOFA and baseline numbers from the referenced Appendix C3 of the initial NO_X BACT Analysis Study report[31]. These numbers assume the reduction in annual plant output is a combination of a reduction of annual operating time and capacity reductions associated with the control alternatives.

---

[31] Ibid Reference number 3, October 2006, pages C3-1 through C3-11.

TABLE C.4-2 – Expected Capacity Reductions for MRYS Unit 2 NO_X Controls

Alt. Label(1)	NOx Control Alternative	Estimated Annual Average Unit Electrical Power Generation Reduction from Operating Time Reduction: Unit Running Plant Capacity Ratio(2)	Unit Generation Reduction(3) kW-hrs/yr	Unit Generation Reduction Cost(4), 1000$/yr
T2	Hypothetical Tail End SCR w/ ASOFA – Scenario A(5)	0.924	170,167,448	5,956
T1	Hypothetical Tail End SCR w/ ASOFA – Scenario B(5)	0.924	622,740,448	21,796
L2	Hypothetical Low-Dust SCR w/ ASOFA – Scenario A(5)	0.929	188,270,368	6,589
L1	Hypothetical Low-Dust SCR w/ ASOFA – Scenario B(5)	0.929	622,740,448	21,796
E	SNCR w/ ASOFA	0.951	110,176,095	3,856
D	Gas Reburn w/ ASOFA	0.943	81,416,590	2,850
C	Lignite Reburn w/ ASOFA	0.948	130,375,506	4,563
B	FLGR w/ ASOFA	0.949	81,910,024	2,867
A	Advanced SOFA (ASOFA)	0.952	75,859,855	2,655
	Baseline	0.952	0	0

(1) - Alternative designation has been previously assigned from least removal to highest removal percentage.

(2) - 12-month baseline running plant capacity ratio is assumed at 95.2 percent (= 440/462). These values reflect estimated amounts of negative annual output capacity impact expected from the implementation of the individual NOx control technique. Used only for calculation of annual power usage in Table C.4-3.

(3) - Annual electricity generation reduction is annual unit operating time reduction multiplied by the 12-month average gross output of 440 MW.

(4) - Annual electricity generation reduction cost is the annual electricity generation reduction (kW-hrs/yr) resulting from the implementation of the individual NOx control technique multiplied by the incremental value of electricity generation, assumed to be $35.00/MW-hr. All cost figures in 2006 dollars.

(5) - The inclusion of tail-end and low-dust SCR technologies in this table does not constitute agreement that it is technically feasible to install these technologies on Unit 2 at Milton R. Young Station. The estimated annual unit running plant capacity ratios shown for hypothetically-applied SCR systems are based on assumptions that known or expected reasons for technical infeasibility for installation and operation and maintenance of the SCR equipment on this boiler are solvable. SCR technology is considered technically infeasible by Minnkota for application at MRYS per the October 2006 NO_X BACT Analysis Study report and subsequent submittals in response to comments by the NDDH, EPA, DOJ and other parties, so this information for the hypothetical application of SCR alternatives is included for comparative purposes only. See Section 4.2.1.2.1 for details of Scenario A and Scenario B that assumes replacement of SCR catalyst after a specified number of hours of unit operation.

Table C.4-3 includes estimated unit gross and net electrical power demands (kilowatts) and annual usage (kW-hrs per year) used to calculate unit generation reductions and replacement electrical power costs due to the four hypothetically-applied SCR cases, along with the ASOFA numbers from the referenced Appendix

C3 of the initial NO_X BACT Analysis Study report [32]. These numbers assume that the reductions of annual operating time and capacity associated with the control alternatives are also applied.

TABLE C.4-3 – Expected Auxiliary Electrical Power Demand Changes for MRYS Unit 2 NO_X Controls

		Estimated Annual Average APC NOx Equipment Auxiliary Electrical Power Demand and Usage				
Alt. Label(1)	**NOx Control Alternative**	**Gross Demand (2) kW**	**Credit(3) kW**	**Total Net Demand(4) kW**	**Power Usage(5) kW-hrs/yr**	**Power Usage Cost(6), 1000$/yr**
T2	Hypothetical Tail End SCR w/ ASOFA – Scenario A(7)	14,925	0	14,925	108,122,807	3,784
T1	Hypothetical Tail End SCR w/ ASOFA – Scenario B(7)	14,925	0	14,925	93,941,913	3,288
L2	Hypothetical Low-Dust SCR w/ ASOFA – Scenario A(7)	12,389	0	12,389	89,740,378	3,141
L1	Hypothetical Low-Dust SCR w/ ASOFA – Scenario B(7)	12,389	0	12,389	78,381,807	2,743
E	SNCR w/ ASOFA	133	0	133	1,008,774	35
D	Gas Reburn w/ ASOFA	1	(228)	(227)	(1,724,428)	(60)
C	Lignite Reburn w/ ASOFA	8,342	(448)	7,894	59,217,554	2,073
B	FLGR w/ ASOFA	1	(125)	(124)	(949,051)	(33)
A	Advanced SOFA (ASOFA)	1	0	1	7,664	0.3

(1) - Alternative designation has been previously assigned from least removal to highest removal percentage.
(2) - The APC NOx equipment gross auxiliary electrical power demand of alternatives is the sum of the demand for individual technologies combined by simple addition. Actual power demands may differ from this due to positive or negative synergistic effects. Coal reburn includes 2,484 kW for feed preparation and conveying equipment demand plus 5,857 kW for the COHPAC system addition for PM control.
(3) - The APC NOx equipment auxiliary electrical power demand credit of coal reburn alternatives is the estimated result of lower cyclone coal preparation and feeder power demand due to lower boiler cyclone coal equipment loading. Actual power demands may differ from this due to accuracy of estimates for assumed amount of operating horsepower reduction.
(4) - The total net auxiliary electrical power demand is the sum of the gross demand and credit.
(5) - The annual change in APC NOx equipment auxiliary electrical power demand electricity usage in kW-hrs/yr for these alternatives is the net power demand multiplied by the estimated annual operating time and running plant capacity ratio which reflects the adjustment for any expected availability and capacity impacts from the implementation of the control technique.
(6) - The annual change in APC NOx equipment auxiliary electrical power demand electricity cost is the annual change in kW-hrs/yr for these alternatives resulting from the implementation of the individual NOx control technique multiplied by the incremental value of electricity generation, assumed to be $35.00/MW-hr. All cost figures in 2006 dollars.
(7) - The inclusion of tail-end and low-dust SCR technologies in this table does not constitute agreement that it is technically feasible to install these technologies on Unit 2 at Milton R. Young Station. The estimated power demand shown for hypothetically-applied SCR systems are based on Burns & McDonnell estimates developed from preliminary equipment and ductwork sizing and designs with vendor budgetary proposals. SCR technology is considered technically infeasible by Minnkota for application at MRYS per the October 2006 NO_X BACT Analysis Study report and subsequent submittals in response to comments by the NDDH, EPA, DOJ and other parties, so this information for the hypothetical application of SCR alternatives is included for comparative purposes only. See Section 4.2.1.2.1 for details of Scenario A and Scenario B that assumes replacement of SCR catalyst after a specified number of hours of unit operation.

---

[32] Ibid Reference number 3, October 2006, pages C3-1 through C3-11.

Table C.4-4 includes estimated net unit electrical annual power usage (kW-hrs per year) and expected reductions in annual operating time to calculate unit generation reductions and replacement electrical power costs due to the four hypothetically-applied SCR cases, along with the ASOFA numbers from the referenced Appendix C3 of the initial NO_X BACT Analysis Study report[33]. These numbers assume the reduction in annual plant output is a combination of a reduction of net unit generation because of electrical power usage and reductions in annual operating time and capacity associated with the control alternatives.

TABLE C.4-4 – Expected Auxiliary Electrical Power Demand and Generation Reduction Cost Changes for MRY Unit 2 NO_X Controls

		Estimated Annual Change in Unit Generation Due to APC NOx Equipment Auxiliary Power Electricity Demand and Generation Reduction			
Alt. Label(1)	**NOx Control Alternative**	**APC Electrical Power Usage(2) kW-hrs/yr**	**Unit Generation Reduction(3) kW-hrs/yr**	**Total Unit Electrical Power Generation Change(4) kW-hrs/yr**	**Total Unit Electrical Power Generation Change Cost(5) 1000$/yr**
T2	Hypothetical Tail End SCR w/ ASOFA – Scenario A(6)	108,122,807	170,167,448	278,290,255	9,740
T1	Hypothetical Tail End SCR w/ ASOFA – Scenario B(6)	93,941,913	622,740,448	716,682,361	25,084
L2	Hypothetical Low-Dust SCR w/ ASOFA – Scenario A(6)	89,740,378	188,270,368	278,010,746	9,730
L1	Hypothetical Low-Dust SCR w/ ASOFA – Scenario B(6)	78,381,807	622,740,448	701,122,255	24,539
E	SNCR w/ ASOFA	1,008,774	110,176,095	111,184,869	3,891
D	Gas Reburn w/ ASOFA	(1,724,428)	81,416,590	79,692,162	2,789
C	Lignite Reburn w/ ASOFA	59,217,554	130,375,506	189,593,059	6,636
B	FLGR w/ ASOFA	(949,051)	81,910,024	80,960,972	2,834
A	Advanced SOFA (ASOFA)	7,664	75,859,855	75,867,520	2,655

(1) - Alternative designation has been previously assigned from least removal to highest removal percentage.

(2) - The annual change in APC NOx equipment auxiliary electrical power demand electricity usage in kW-hrs/yr for these alternatives is the net power demand multiplied by the estimated annual operating time and running plant capacity ratio which reflects the adjustment for any expected availability and capacity impacts from the implementation of the control technique.

(3) - Annual electricity generation reduction is annual operating time reduction multiplied by the 12-month average gross output of 440 MW.

(4) - The total unit electrical power generation change is the sum of the annual change in APC NOx equipment auxiliary electrical power demand electricity usage plus the annual electricity generation reduction resulting from the implementation of the individual NOx control alternative.

(5) - The total unit electrical power generation change cost is the total generation change (kw-hrs/yr) multiplied by the incremental value of replacement electricity generation, assumed to be $35.00/MW-hr. All cost figures in 2006 dollars.

---

[33] Ibid Reference number 2, October 2006, pages C3-1 through C3-11.

(6) - The inclusion of tail-end and low-dust SCR technologies in this table does not constitute agreement that it is technically feasible to install these technologies on Unit 2 at Milton R. Young Station. The estimated power demand shown for hypothetically-applied SCR systems are based on Burns & McDonnell estimates developed from preliminary equipment and ductwork sizing and designs with vendor budgetary proposals. SCR technology is considered technically infeasible by Minnkota for application at MRYS per the October 2006 NO_X BACT Analysis Study report and subsequent submittals in response to comments by the NDDH, EPA, DOJ and other parties, so this information for the hypothetical application of SCR alternatives is included for comparative purposes only. See Section 4.2.1.2.1 for details of Scenario A and Scenario B that assume replacement of SCR catalyst after a specified number of hours of unit operation.

4.2.1.3 LEVELIZED TOTAL ANNUAL COST ESTIMATES FOR MRY STATION NO_X CONTROLS

A comparison of the control versus cost-effectiveness of two hypothetical SCR cases and previously-analyzed feasible NO_X control alternatives on Milton R. Young Unit 2 was made. This is summarized as shown in Tables 4-7SA and 4-7SF, Figures 4-1SA and 4-1SF, and Figures 4-2SA and 4-2SF for MRY Station Unit 2.

TABLE 4-7SA – Estimated Annual Emissions and Levelized Total Annual Cost for NO_X Control Alternatives - MRY Station Unit 2 - Stand Alone SCR Projects

Alt. Label(1)	NOx Control Alternative	Annual NOx Emissions(2) Tons/yr	Annual NOx Emissions Reduction(3) Tons/yr	Levelized Total Annual Cost(4) $1,000	Average Control Cost(5) $/ton
T2	Hypothetical Tail End SCR w/ ASOFA – Scenario A(6)	936	14,857	69,057	4,648
T1	Hypothetical Tail End SCR w/ ASOFA – Scenario B(6)	813	14,980	98,818	6,597
L2	Hypothetical Low-Dust SCR w/ ASOFA – Scenario A(6)	931	14,862	59,881	4,029
L1	Hypothetical Low-Dust SCR w/ ASOFA – Scenario B(6)	813	14,980	89,072	5,946
E	SNCR w/ ASOFA	6,421	9,372	11,618	1,240
D	Gas Reburn w/ ASOFA	6,882	8,910	63,892(7)	7,171
C	Lignite Reburn w/ ASOFA	6,964	8,829	19,475(8)	2,206
B	FLGR w/ ASOFA	8,490	7,303	29,317(7)	4,014
A	Advanced SOFA (ASOFA)	9,621	6,172	4,376	709
	Baseline	15,793	0	0	

(1) - Alternative label has been assigned from highest to lowest unit NOx emission rate.

(2) - Estimated annual emission tons assume an annual unit uptime availability factor specific to each alternative; 15,793 (= 0.939*8760*3,839/2000) was assumed for the baseline case.

(3) - Estimated annual tons of emission reduction is the difference between annual baseline tons and each alternative's annual emissions (tons).

(4) - Levelized Total Annual Cost = Annualized Installed Capital Cost + Levelized Annual O&M cost. See note 3 from Tables 4-4SA and 4-6SA for annualized cost factors. Emissions are calculated from unit emission rates, control percentage,

hourly heat input, and annual hrs/yr operation compared to pre-control baseline emissions based on annual operation at baseline pre-control NOx emission rate.

(5) - Average Control Cost Effectiveness ($/ton) is the Levelized Total Annual Cost ($/yr) divided by Annual Emission Reduction (tons/yr). All cost figures in 2006 dollars.

(6) - The inclusion of tail-end and low-dust SCR technologies in this table does not constitute agreement that it is technically feasible to install these technologies on Unit 2 at Milton R. Young Station. The estimated annual NOx removal and LTAC shown for a hypothetically-applied SCR system is based on assumptions that known or expected reasons for technical infeasibility for installation of the SCR equipment on this boiler are unsolvable. Costs are derived from Burns & McDonnell internal database and cost estimate specifically for MRYS Unit 2 in 2006 dollars. SCR technology is considered technically infeasible by Minnkota for application at MRYS per the October 2006 NO_X BACT Analysis Study report and subsequent submittals in response to comments by the NDDH, EPA, DOJ and other parties, so this information for the hypothetical application of SCR alternatives is included for comparative purposes only. See Section 4.2.1.2.1 for details of Scenario A and Scenario B that assumes replacement of SCR catalyst after a specified number of hours of unit operation.

(7) - LTAC for gas reburn options include high-pressure natural gas supply pipeline annualized capital cost of $1,307,000/yr for CGR and $653,000 for FLGR. See footnote number 8 under Table 4-3SA.

(8) - LTAC for increased PM collection capacity included in lignite reburn option are approximately $3,140,000 for annualized capital cost plus $4,194,000/yr for annualized O&M cost, for a LTAC subtotal of $7,333,000/yr.

TABLE 4-7SF – Estimated Annual Emissions and Levelized Total Annual Cost for NO_X Control Alternatives - MRY Station Unit 2 - Shared Facilities SCR Projects

Alt. Label(1)	NOx Control Alternative	Annual NOx Emissions(2) Tons/yr	Annual NOx Emissions Reduction(3) Tons/yr	Levelized Total Annual Cost(4) $1,000	Average Control Cost(5) $/ton
T2	Hypothetical Tail End SCR w/ ASOFA – Scenario A(6)	936	14,857	66,506	4,477
T1	Hypothetical Tail End SCR w/ ASOFA – Scenario B(6)	813	14,980	96,268	6,427
L2	Hypothetical Low-Dust SCR w/ ASOFA – Scenario A(6)	931	14,862	57,351	3,859
L1	Hypothetical Low-Dust SCR w/ ASOFA – Scenario B(6)	813	14,980	86,542	5,777
E	SNCR w/ ASOFA	6,421	9,372	11,618	1,240
D	Gas Reburn w/ ASOFA	6,882	8,910	63,892(7)	7,171
C	Lignite Reburn w/ ASOFA	6,964	8,829	19,475(8)	2,206
B	FLGR w/ ASOFA	8,490	7,303	29,317(7)	4,014
A	Advanced SOFA (ASOFA)	9,621	6,172	4,376	709
	Baseline	15,793	0	0	

(1) - Alternative label has been assigned from highest to lowest unit NOx emission rate.

(2) - Estimated annual emission tons assume an annual unit uptime availability factor specific to each alternative; 15,793 (= 0.939*8760*3,839/2000) was assumed for the baseline case.

(3) - Estimated annual tons of emission reduction is the difference between annual baseline tons and each alternative's annual emissions (tons).

(4) - Levelized Total Annual Cost = Annualized Installed Capital Cost + Levelized Annual O&M cost. See note 3 from Tables 4-4SF and 4-6SF for annualized cost factors. Emissions are calculated from unit emission rates, control

percentage, hourly heat input, and annual hrs/yr operation compared to pre-control baseline emissions based on annual operation at baseline pre-control NOx emission rate.

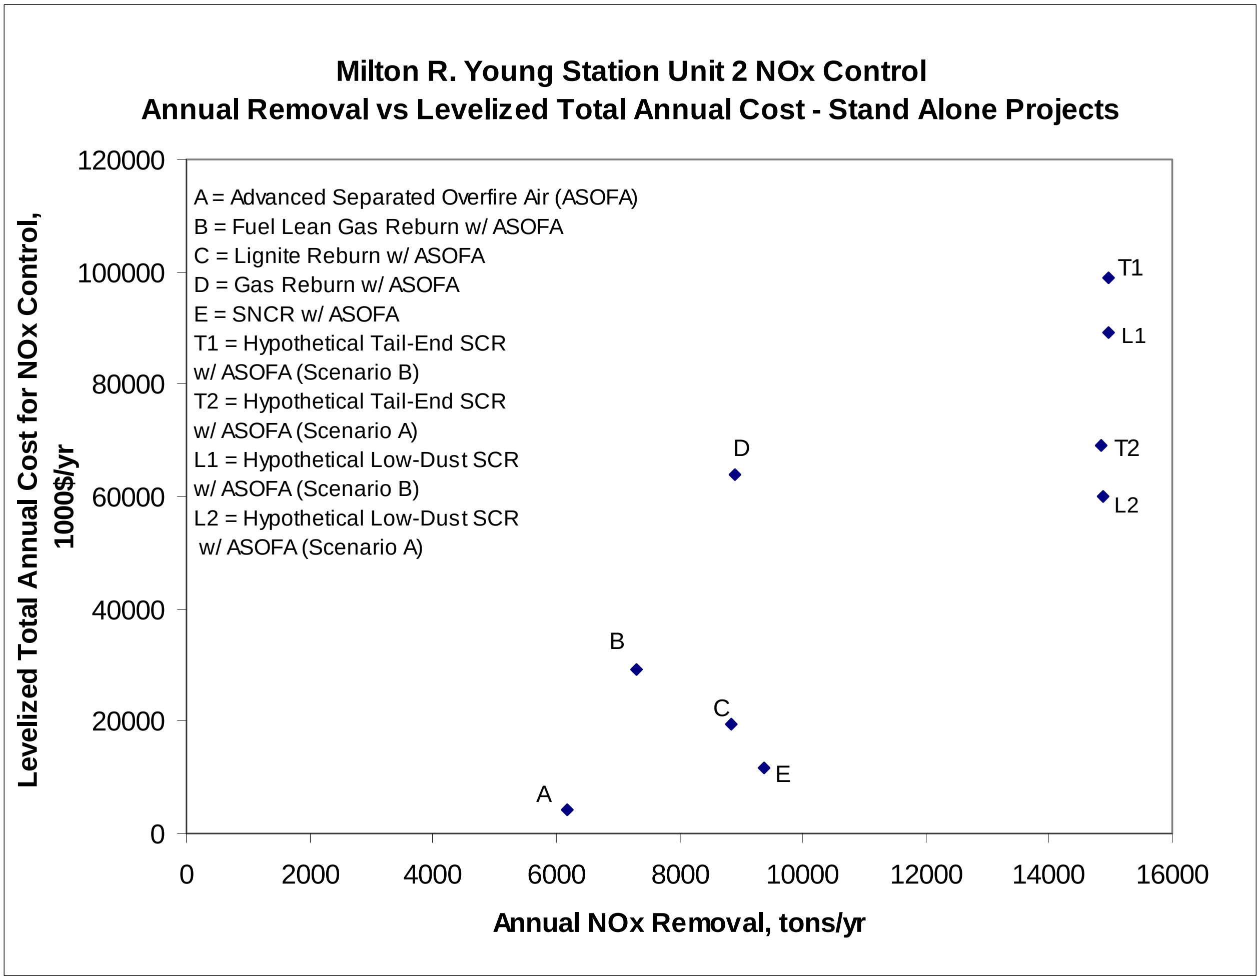
(5) - Average Control Cost Effectiveness ($/ton) is the Levelized Total Annual Cost ($/yr) divided by Annual Emission Reduction (tons/yr). All cost figures in 2006 dollars.

(6) - The inclusion of tail-end and low-dust SCR technologies in this table does not constitute agreement that it is technically feasible to install these technologies on Unit 2 at Milton R. Young Station. The estimated annual NOx removal and LTAC shown for a hypothetically-applied SCR system is based on assumptions that known or expected reasons for technical infeasibility for installation of the SCR equipment on this boiler are unsolvable. Costs are derived from Burns & McDonnell internal database and cost estimate specifically for MRYS Unit 2 in 2006 dollars. SCR technology is considered technically infeasible by Minnkota for application at MRYS per the October 2006 NO_X BACT Analysis Study report and subsequent submittals in response to comments by the NDDH, EPA, DOJ and other parties, so this information for the hypothetical application of SCR alternatives is included for comparative purposes only. See Section 4.2.1.2.1 for details of Scenario A and Scenario B that assumes replacement of SCR catalyst after a specified number of hours of unit operation.

(7) - LTAC for gas reburn options include high-pressure natural gas supply pipeline annualized capital cost of $1,307,000/yr for CGR and $653,000 for FLGR. See footnote number 8 under Table 4-3SF.

(8) - LTAC for increased PM collection capacity included in lignite reburn option are approximately $3,140,000 for annualized capital cost plus $4,194,000/yr for annualized O&M cost, for a LTAC subtotal of $7,333,000/yr.

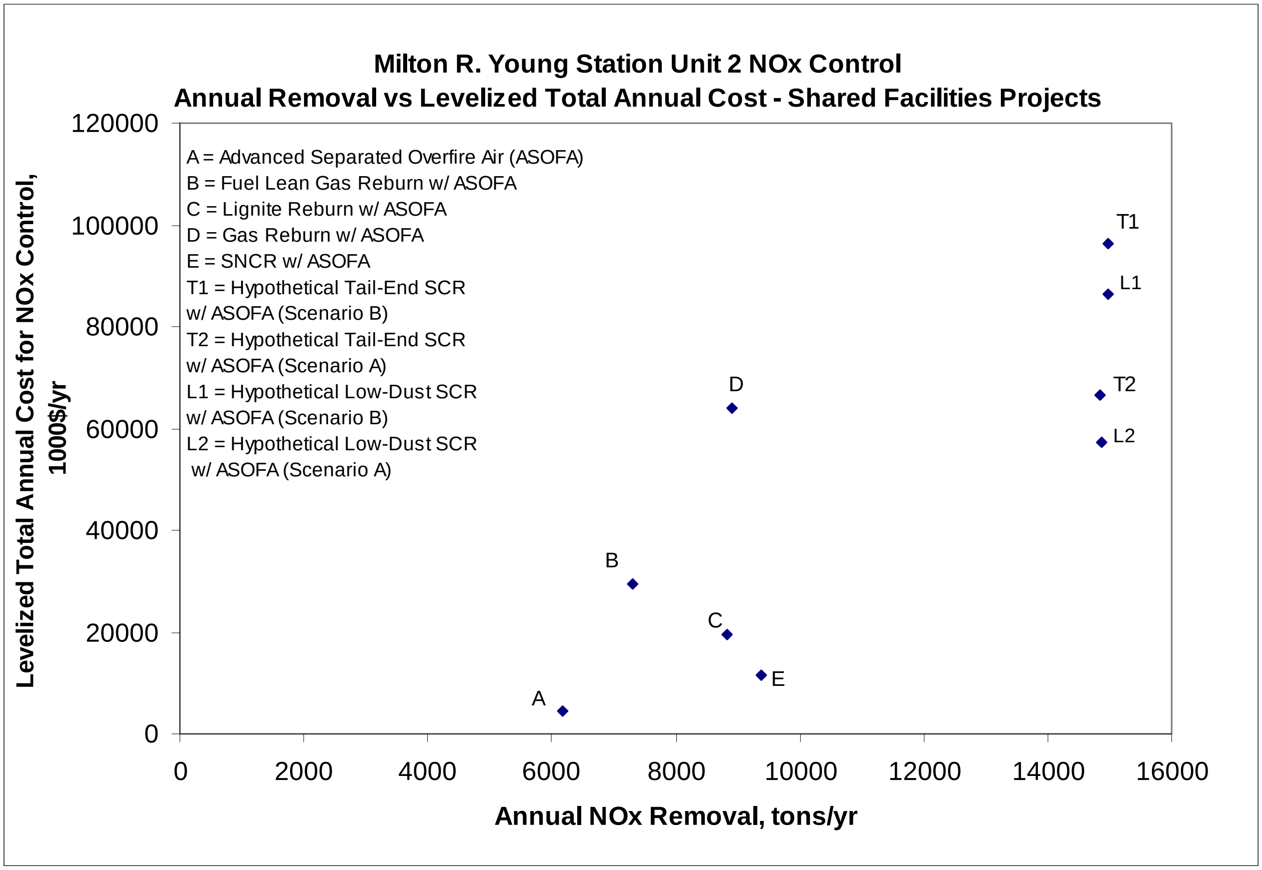
Figure 4-1SA – NO_X Control Cost Effectiveness - MRY Station Unit 2[(1)]
Stand Alone SCR Projects



(1) - All cost figures in 2006 dollars. Numbers are listed and qualifiers are noted in Table 4-7SA.

(2) - The inclusion of tail-end and low-dust SCR technologies in this figure does not constitute agreement that it is technically feasible to install these technologies on Unit 2 at Milton R. Young Station. The estimated annual NOx removal and LTAC shown for a hypothetically-applied SCR system is based on assumptions that known or expected reasons for technical infeasibility for installation of the SCR equipment on this boiler are solvable. SCR technology is considered technically infeasible by Minnkota for application at MRYS per the October 2006 NO_X BACT Analysis Study report and subsequent submittals in response to comments by the NDDH, EPA, DOJ and other parties, so this information for the hypothetical application of SCR alternatives is included for comparative purposes only. See Section 4.2.1.2.1 for details of Scenario A and Scenario B that assumes replacement of SCR catalyst after a specified number of hours of unit operation.

Figure 4-1SF – NO_X Control Cost Effectiveness - MRY Station Unit 2(1) Shared Facilities SCR Projects



(1) - All cost figures in 2006 dollars. Numbers are listed and qualifiers are noted in Table 4-7SF.

(2) - The inclusion of tail-end and low-dust SCR technologies in this figure does not constitute agreement that it is technically feasible to install these technologies on Unit 2 at Milton R. Young Station. The estimated annual NOx removal and LTAC shown for a hypothetically-applied SCR system is based on assumptions that known or expected reasons for technical infeasibility for installation of the SCR equipment on this boiler are solvable. SCR technology is considered technically infeasible by Minnkota for application at MRYS per the October 2006 NO_X BACT Analysis Study report and subsequent submittals in response to comments by the NDDH, EPA, DOJ and other parties, so this information for the hypothetical application of SCR alternatives is included for comparative purposes only. See Section 4.2.1.2.1 for details of Scenario A and Scenario B that assumes replacement of SCR catalyst after a specified number of hours of unit operation.

The purpose of Figures 4-1SA and 4-1SF is to show the range of control and cost for four hypothetically-applied SCR cases and previously-analyzed feasible NO_X control alternatives on Milton R. Young Unit 2 alternatives evaluated.

Data points for conventional gas reburn (Point D) and fuel-lean gas reburn (Point B) with advanced separated overfire air, and lignite reburn with ASOFA (Point C), in Figures 4-1SA and 4-1SF are inferior and therefore were eliminated from further control cost-effectiveness analysis.

A dominant set of control alternatives was determined by generating what is called the "envelope of least-cost alternatives". The dominant controls cost curve is the best fit line through the points forming the rightmost boundary of the data zone on a scatter plot of the annual NO_X removal tonnage versus LTAC for the various remaining BACT alternatives. Average and incremental annual costs and NO_X emission reductions for the dominant least-cost control alternatives remaining after the elimination of the obviously inferior options are listed in Tables 4-8SA and 4-8SF.

TABLE 4-8SA – Dominant Controls Cost Curve Points for NO_X Control Alternatives - MRY Station Unit 2 - Stand Alone Projects

Alt. Label[(1)]	NOx Control Alternative	Levelized Total Annual Cost[(2),(3)] ($1,000/yr)	Annual Emission Reduction[(3)] (tpy)	Incremental Levelized Total Annual Cost[(2),(4)] ($1,000/yr)	Incremental Annual Emission Reduction[(4)] (tpy)	Incremental Control Cost Effectiveness ($/ton)[(2),(4)]
T2	Hypothetical Tail End SCR w/ ASOFA – Scenario A[(5)]	69,057	14,857	57,439	5,485	10,472
T1	Hypothetical Tail End SCR w/ ASOFA – Scenario B[(5)]	98,818	14,980	87,200	5,608	15,550
L2	Hypothetical Low-Dust SCR w/ ASOFA – Scenario A[(5)]	59,881	14,862	48,263	5,490	8,792
L1	Hypothetical Low-Dust SCR w/ ASOFA – Scenario B[(5)]	89,072	14,980	77,454	5,608	13,812
E	SNCR w/ ASOFA	11,618	9,372	7,242	3,200	2,263
A	Advanced SOFA (ASOFA)	4,376	6,172	4,376	6,172	709

(1) - Alternative label has been assigned from highest to lowest unit NOx emission rate. Dominant controls cost curve points from lowest (ASOFA) to highest (TESCR w/ ASOFA-16,000 hrs) are labeled the same as in Table 4-7SA, and on the graphs that accompany this table (Points B, C, and D were eliminated).

(2) - All cost figures in 2006 dollars.

(3) - Annual emission reduction and levelized control cost of these alternatives is relative to current costs and pre-control unit MCR baseline emission rate.

(4) - Increment based upon comparison between consecutive alternatives (points) from lowest to highest.

(5) - The inclusion of tail-end and low-dust SCR technologies in this table does not constitute agreement that it is technically feasible to install these technologies on Unit 2 at Milton R. Young Station. The annual NOx removal and LTAC shown for a hypothetically-applied SCR system is based on assumptions that known or expected reasons for technical infeasibility for installation of the SCR equipment on this boiler are solvable. SCR technology is considered technically infeasible by Minnkota for application at MRYS per the October 2006 NO_X BACT Analysis Study report and subsequent submittals in response to comments by the NDDH, EPA, DOJ and other parties, so this information for the hypothetical application of SCR alternatives is included for comparative purposes only. See Section 4.2.1.2.1 for details of Scenario A and Scenario B that assumes replacement of SCR catalyst after a specified number of hours of unit operation.

TABLE 4-8SF – Dominant Controls Cost Curve Points for NO_X Control Alternatives - MRY Station Unit 2 - Shared Facilities Projects

Alt. Label(1)	**NOx Control Alternative**	**Levelized Total Annual Cost(2),(3) ($1,000/yr)**	**Annual Emission Reduction(3) (tpy)**	**Incremental Levelized Total Annual Cost(2),(4) ($1,000/yr)**	**Incremental Annual Emission Reduction(4) (tpy)**	**Incremental Control Cost Effectiveness ($/ton)(2),(4)**
T2	Hypothetical Tail End SCR w/ ASOFA – Scenario A(5)	66,506	14,857	54,888	5,485	10,007

A	Advanced SOFA (ASOFA)	4,376	6,172	4,376	6,172	709

(1) - Alternative label has been assigned from highest to lowest unit NOx emission rate. Dominant controls cost curve points from lowest (ASOFA) to highest (TESCR w/ ASOFA-16,000 hrs) are labeled the same as in Table 4-7SF, and on the graphs that accompany this table (Points B, C, and D were eliminated).

(2) - All cost figures in 2006 dollars.

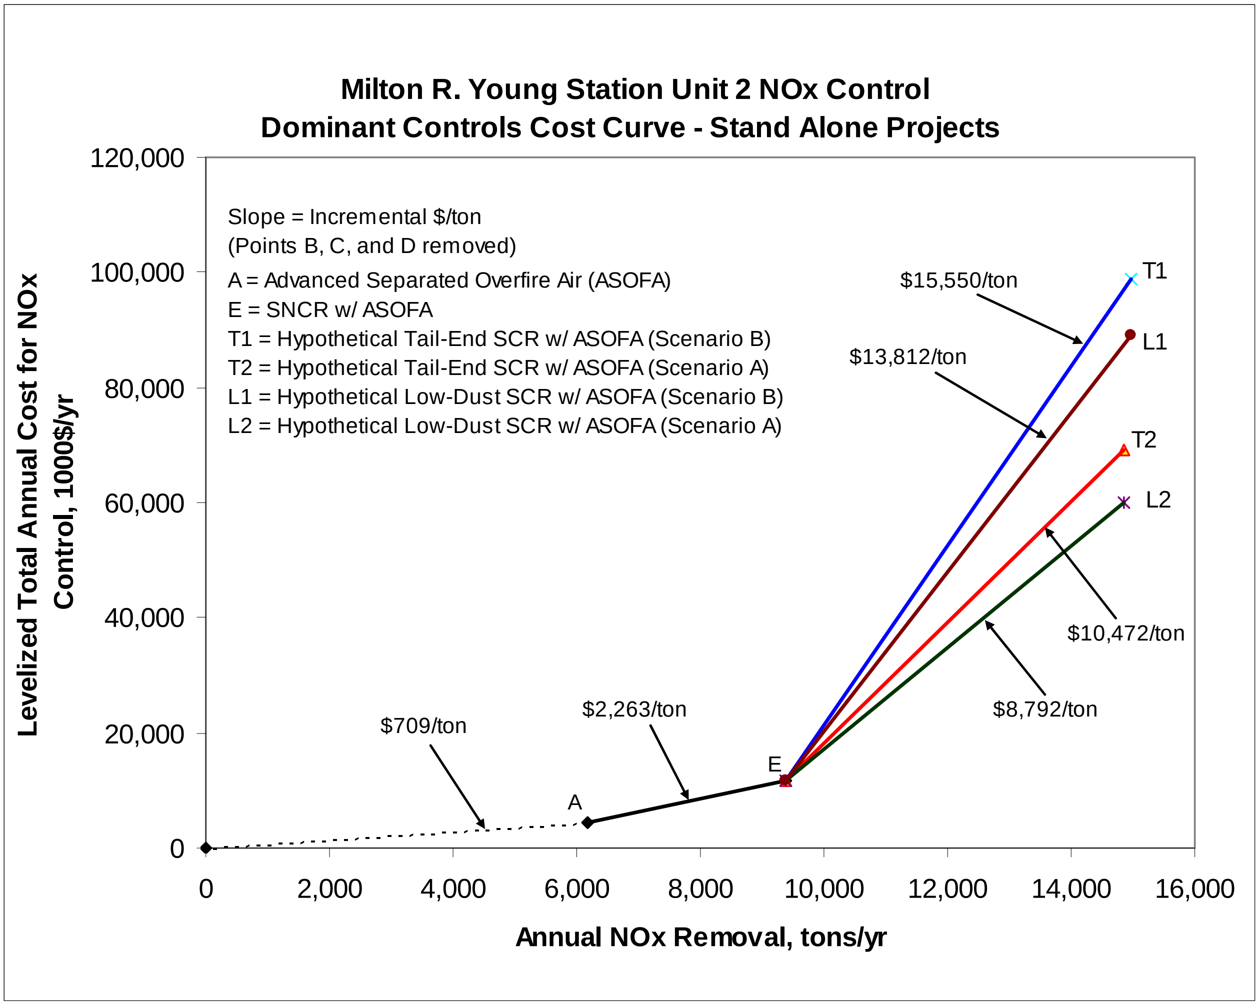
(3) - Annual emission reduction and levelized control cost of these alternatives is relative to current costs and pre-control unit MCR baseline emission rate.

(4) - Increment based upon comparison between consecutive alternatives (points) from lowest to highest.

(5) - The inclusion of tail-end and low-dust SCR technologies in this table does not constitute agreement that it is technically feasible to install these technologies on Unit 2 at Milton R. Young Station. The annual NOx removal and LTAC shown for a hypothetically-applied SCR system is based on assumptions that known or expected reasons for technical infeasibility for installation of the SCR equipment on this boiler are solvable. SCR technology is considered technically infeasible by Minnkota for application at MRYS per the October 2006 NO_X BACT Analysis Study report and subsequent submittals in response to comments by the NDDH, EPA, DOJ and other parties, so this information for the hypothetical application of SCR alternatives is included for comparative purposes only. See Section 4.2.1.2.1 for details of Scenario A and Scenario B that assumes replacement of SCR catalyst after a specified number of hours of unit operation.

Figures 4-2SA and 4-2SF contain a repetition of the levelized total annual cost and NO_X control information from Figure 4-1SA and 4-2SF for MRY Station Unit 2, with Point B (FLGR™ with ASOFA), Point C (Lignite Reburn with ASOFA) and Point D (conventional gas reburn with ASOFA) removed. This is the dominant controls cost curve for MRY Station Unit 2 NO_X emissions alternatives.

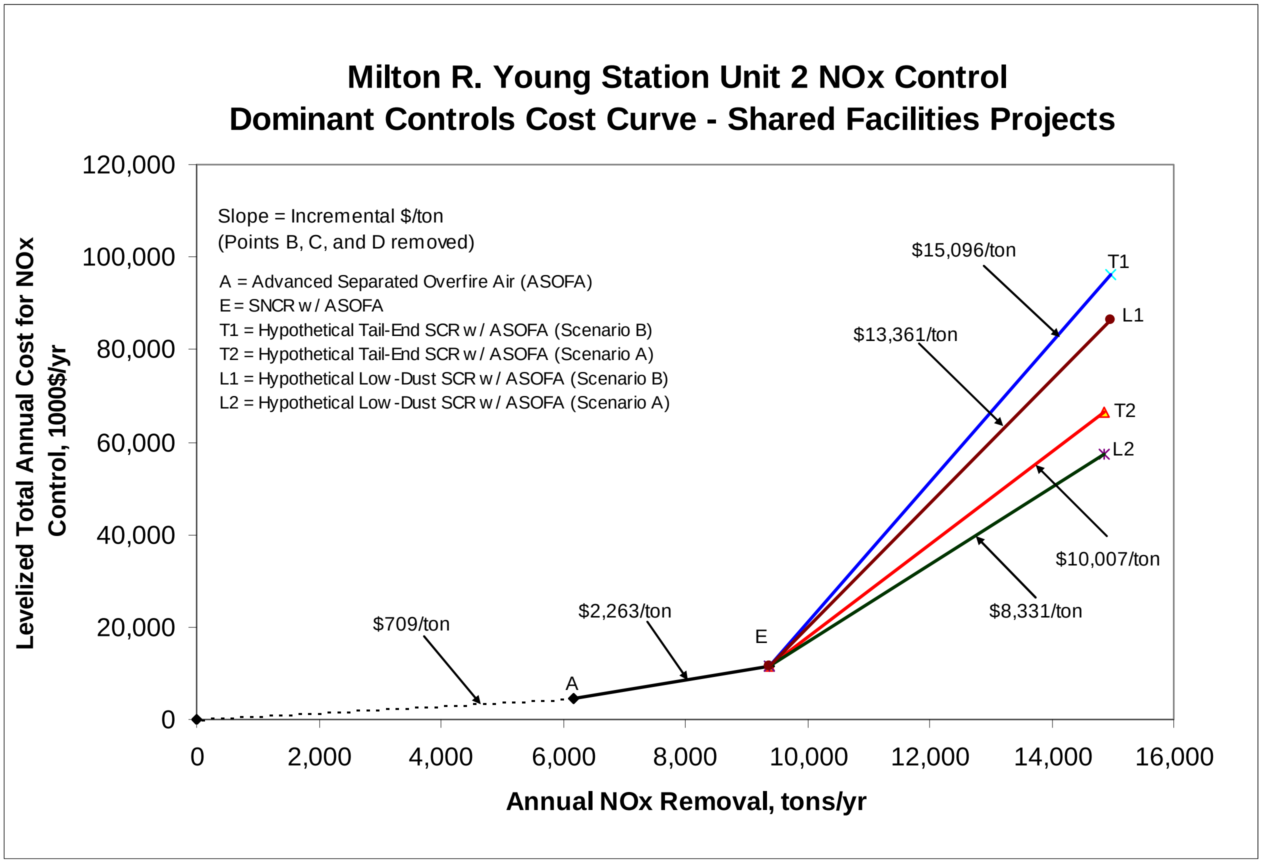
Figure 4-2SA – MRY Station Unit 2 NO_X Control Alternatives BACT Dominant Controls Cost Curve$^{(1)}$ - Stand Alone SCR Projects



(1) - All cost figures in 2006 dollars. Numbers are listed and qualifiers are noted in Table 4-8SA.

(2) - The inclusion of tail-end and low-dust SCR technologies in this figure does not constitute agreement that it is technically feasible to install these technologies on Unit 2 at Milton R. Young Station. The estimated annual NOx removal and LTAC shown for a hypothetically-applied SCR system is based on assumptions that known or expected reasons for technical infeasibility for installation and operation and maintenance of the SCR equipment on this boiler are solvable. SCR technology is considered technically infeasible by Minnkota for application at MRYS per the October 2006 NO_X BACT Analysis Study report and subsequent submittals in response to comments by the NDDH, EPA, DOJ and other parties, so this information for the hypothetical application of SCR alternatives is included for comparative purposes only. See Section 4.2.1.2.1 for details of Scenario A and Scenario B that assumes replacement of SCR catalyst after a specified number of hours of unit operation.

**Figure 4-2SF – MRY Station Unit 2 NO_X Control Alternatives
BACT Dominant Controls Cost Curve(1) – Shared Facilities SCR Projects**



(1) - All cost figures in 2006 dollars. Numbers are listed and qualifiers are noted in Table 4-8SF.

(2) - The inclusion of tail-end and low-dust SCR technologies in this figure does not constitute agreement that it is technically feasible to install these technologies on Unit 2 at Milton R. Young Station. The estimated annual NOx removal and LTAC shown for a hypothetically-applied SCR system is based on assumptions that known or expected reasons for technical infeasibility for installation and operation and maintenance of the SCR equipment on this boiler are solvable. SCR technology is considered technically infeasible by Minnkota for application at MRYS per the October 2006 NO_X BACT Analysis Study report and subsequent submittals in response to comments by the NDDH, EPA, DOJ and other parties, so this information for the hypothetical application of SCR alternatives is included for comparative purposes only. See Section 4.2.1.2.1 for details of Scenario A and Scenario B that assumes replacement of SCR catalyst after a specified number of hours of unit operation.

As can be seen from a review of Table 4-7SA and Table 4-7SF, the average control cost effectiveness (called the unit control cost in this report) ranges from approximately $709/ton to $7,171/ton of MRYS Unit 2's NO_X emissions removed. The unit control cost for the hypothetically-applied Scenario A Tail End SCR w/ ASOFA case was $4,648/ton and for the hypothetically-applied Scenario B Tail End SCR w/ ASOFA case was $6,597/ton (stand alone projects). The unit control cost for the hypothetically-applied Scenario A Low-Dust SCR w/ ASOFA case was $4,029/ton and for the hypothetically-applied Scenario B Low-Dust SCR w/ ASOFA case was $5,946/ton (stand alone projects). The unit control cost for the hypothetically-applied Scenario A Tail End SCR w/ ASOFA case was $4,477/ton and for the hypothetically-applied

Scenario B Tail End SCR w/ ASOFA case was $6,427/ton (shared facilities projects). The unit control cost for the hypothetically-applied Scenario A Low-Dust SCR w/ ASOFA case was $3,859/ton and for the hypothetically-applied Scenario B Low-Dust SCR w/ ASOFA case was $5,777/ton (shared facilities projects). Unit control cost for SNCR w/ ASOFA was $1,240/ton, nearly twice that of ASOFA ($709/ton). It should be noted, however, that very high estimated average control costs involve fuel lean gas reburn ($4,014/ton) and conventional gas reburn ($7,171/ton) technologies that were previously shown to be inferior options (not on the dominant controls cost curve) and thus were eliminated from further impacts analysis.

The incremental cost analysis indicates that from a cost effectiveness viewpoint, the SNCR with ASOFA alternative for MRYS Unit 2 incurs a significant annual (levelized) incremental cost compared to the ASOFA NO_X control technique. The slope from zero (baseline) to ASOFA (Point A) was $709/ton; the incremental cost per ton (slope) from ASOFA (Point A) to SNCR with ASOFA (Point E) was $2,263/ton for MRYS Unit 2. The incremental cost per ton (slope) from SNCR with ASOFA (Point E) to the top hypothetically-applied low-dust SCR case (Point L2, Scenario A) was $8,792/ton (stand alone projects). The incremental cost per ton (slope) from SNCR with ASOFA (Point E) to the top hypothetically-applied tail end SCR case (Point T2, Scenario A) was $10,472/ton (stand alone projects). The incremental cost per ton (slope) from SNCR with ASOFA (Point E) to the second hypothetically-applied low-dust SCR case (Point L1, Scenario B) was $13,812/ton (stand alone projects). The incremental cost per ton (slope) from SNCR with ASOFA (Point E) to the second hypothetically-applied tail end SCR case (Point T1, Scenario B) was $15,550/ton (stand alone projects). For shared projects, the incremental cost per ton (slope) from SNCR with ASOFA (Point E) to the top hypothetically-applied SCR cases were $8,331/ton (low-dust Point L2, Scenario A) and $10,007/ton (tail end Point T2, Scenario A). For shared projects, the incremental cost per ton (slope) from SNCR with ASOFA (Point E) to the second hypothetically-applied SCR cases were $13,361/ton (low-dust, Point L1, Scenario B) and $15,096/ton (tail end Point T1, Scenario B).

In the U.S. EPA's NSR Manual, the EPA does not specify acceptable or unacceptable ranges for average (unit control costs) and incremental cost effectiveness values. EPA's NSR Manual however, does specifically address the standard to be used when rejecting a candidate technology on the basis of adverse economic impact:

> "Consequently, where unusual factors exist that result in cost/economic impacts beyond the range normally incurred by other sources in that category, the technology can be eliminated provided the applicant has adequately identified the circumstances,

> including the cost or other analyses, that show what is significantly different about the proposed source."[34]

This supplemental report for the MRYS NOx BACT Analysis has clearly established the circumstances, including the economic impacts, which would make the hypothetical application of TESCR or LDSCR to MRYS Unit 2 significantly more expensive than SCR costs normally incurred by other coal-fired steam electric generating units. The following information further supports EPA's own statements regarding the costs "normally incurred by other sources". The EPA's technical support document issued with the final Regional Haze Regulations and BART Guidelines estimated an average control cost for SCR applied to MRYS Unit 2 of $537 per ton[35]. The unadjusted unit capital cost versus capacity factor assumed by the EPA for SCR retrofits applied to cyclone boilers in the cost-effectiveness analysis used for establishing presumptive BART[36] was $100/kW. The EPA's cost-effectiveness analysis used for establishing presumptive BART stated that "applying SCR for coal-fired cyclone units is typically less than $1500 a ton, and that the average cost-effectiveness is $900 per ton" [37]. The site-specific control costs estimated for hypothetical application of tail-end and low-dust SCR alternatives to MRYS Unit 2 are significantly higher than the EPA's cost-effectiveness analysis for conventional SCR technologies included in the technical support document issued with the final Regional Haze Regulations and BART Guidelines discussed above.

Also, the use of incremental cost effectiveness is warranted per the final 2005 RHR/BART Guidelines, which state "the greater the number of possible control options that exist, the more weight should be given to the incremental costs vs. average costs". Also in the final 2005 RHR/BART Guidelines, "the average cost for each [of two options, A and B]… may be deemed to be reasonable. However, the incremental cost…of the additional emissions reductions to be achieved by control B may be very great. In such an instance, it may be inappropriate to chose control B, based on its higher incremental costs, even though its average cost may be considered reasonable".[38]

C	Lignite Reburn w/ ASOFA	0.360	1,759	6,964	8,829	54.2	81,167	9,929	19,475(9)	2,206
B	FLGR w/ ASOFA	0.432	2,110	8,490	7,303	45.0	21,817	21,954	29,317(9)	4,014
A	Advanced SOFA (ASOFA)	0.489	2,391	9,621	6,172	37.7	10,008	2,805	4,376	709
	Baseline	0.786	3,839	15,793	0	-	0	0	0	

(1) - Alternative label has been assigned from highest to lowest unit NOx emission rate.

(2) - Estimated NO$_X$ control level reductions relative to average annual unit emission baseline of 0.786 lb/mmBtu at 4,885 mmBtu/hr MCR heat input. Emissions are calculated from unit emission rates, control percentage, hourly heat input, and annual hrs/yr operation compared to pre-control baseline based on annual operation at a gross unit electrical output of 440 MWg and assumes a 93.9% average annual availability. Values from reported emission data for the 12 month operating period during 2001-2005 with the highest rolling summation of NOx pounds.

(3) - Installed capital cost is estimated for determination of total capital cost for a particular technology or combination, assuming 477 MWg unit capacity rating. All cost figures in 2006 dollars. Costs for gas reburn options include high-pressure natural gas supply pipeline installed capital cost of $14,988,000 for CGR and $7,494,000 for FLGR, and annualized capital cost of $1,307,000/yr for CGR and $653,000 for FLGR. Costs for increased PM collection capacity included in lignite reburn option are $36,013,000 for installed capital cost.

(4) - Annual operating and maintenance cost for a particular technology or combination is compared to unit baseline operation at a gross unit electrical output of 440 MWg and assumes a 95.2% average running plant capacity ratio compared to nominal unit gross electrical output capacity of 462 MWg. All cost figures in 2006 dollars. Costs for increased PM collection capacity included in lignite reburn option are $3,155,000/yr for annual O&M cost.

(5) - Levelized Total Annual Cost = Annualized Installed Capital Cost + Levelized Annual O&M cost. Annualized capital cost = Installed capital cost x 0.08718 annualized capital cost factor. Levelized annual O&M cost = Annual O&M cost x 1.24873 annualized O&M cost factor.

(6) - Average Control Cost Effectiveness ($/ton) is the Levelized Total Annual Cost (1000$) divided by Annual Emission Reduction (tons). All cost figures in 2006 dollars.

(7) - The inclusion of tail-end and low-dust SCR technologies in this table does not constitute agreement that these technologies are technically feasible to install on Unit 2 at Milton R. Young Station. The estimated annual NOx removal and LTAC shown for a hypothetically-applied SCR system is based on assumptions that known or expected reasons for technical infeasibility for installation and operation and maintenance of the SCR equipment on this boiler are solvable. SCR technology is considered technically infeasible by Minnkota for application at MRYS per the October 2006 NO$_X$ BACT Analysis Study report and subsequent submittals in response to comments by the NDDH, EPA, DOJ and other parties, so this information for the hypothetical application of SCR alternatives is included for comparative purposes only. See Section 4.2.1.2.1 for details of Scenario A and Scenario B that assumes replacement of SCR catalyst after a specified number of hours of unit operation.

(8) - The stated overall control percentage includes the anticipated long-term emission reduction of 90% design removal from a baseline of 0.49 lb/mmBtu resulting from an advanced separated overfire air system, with air-staged low-NO$_X$ cyclone combustion. Without a separated overfire air system operation or any other technique employed, the assumed emission rate would be 0.079 lb/mmBtu, for an overall reduction of 90 percent from a baseline of 0.786 lb/mmBtu.

(9) - LTAC for reburn options include high-pressure natural gas supply pipeline annualized capital cost of $1,307,000/yr for CGR and $653,000 for FLGR; LTAC for increased PM collection capacity included in lignite reburn option are $3,140,000 for annualized capital cost plus $3,940,000/yr for annualized O&M cost, for a total of $7,080,000/yr.

The other elements of the fourth step of a BACT analysis following economic impacts are to evaluate the following impacts of feasible emission controls:

(1) The energy impacts.
(2) The environmental impacts.

4.2.2 ENERGY IMPACTS OF HYPOTHETICALLY-APPLIED SCR NO_X CONTROL ALTERNATIVES FOR MRY STATION UNIT 2

Operation of the NO_X control technologies on the dominant controls cost curve for potential application at the Milton R. Young Station impose direct impacts on the consumption of energy required for the production of electric power at the facility. The details of estimated energy usage and costs for the previously-evaluated NO_X control alternatives were described and summarized in Section 3.4.2 and Appendix C3 of the October 2006 NOx BACT Analysis Study report[39].

The hypothetical application of Tail End and Low-Dust SCR w/ ASOFA alternatives involve higher energy consumption compared with the existing operation of MRYS Unit 2. New induced draft booster fan electrical power demand is needed due to the estimated additional flue gas pressure drop resulting from hypothetical application of SCR reactor, ductwork, and gas-to-gas heat exchangers. The additional auxiliary electric power demands for the hypothetical application of TESCR and LDSCR equipment were calculated to be 14.9 MW and 12.4 MW, respectively, using estimated annual average electrical loads of the booster fan, urea-to-ammonia conversion fired heater combustion/dilution air fan, direct-fired flue gas reheat burner combustion air fan, and service and sootblowing air compressor equipment and related auxiliary equipment.

Preliminary conceptual design details were developed for these alternatives. An estimated additional 10 inches w.c. of flue gas pressure drop was assumed for each hypothetical application of low-dust SCR system, and an estimated additional 16 inches w.c. of flue gas pressure drop was assumed for the hypothetical application of tail end SCR system. Equipment and ductwork arrangements and expected severe fouling of the catalyst for the hypothetical application of SCR system ductwork, reactor, and gas-gas reheater changes may cause significantly more restrictive flow paths. Thus the electrical power usage estimated here may be too low.

---

[39] Ibid Reference number 3, October 2006, pages 3-31 through 3-35, and Appendix pages C3-7 through C3-10.

The expected loss of electrical power generation from these reductions in net output was included as a cost, assuming $35 per megawatt-hour for replacement electrical power. Energy impacts of installing hypothetical applications of low-dust and tail end SCR alternatives for NO_X control were included in the O&M cost section (4.2.1.2.1) of this supplemental analysis as Tables C.4-2 through C.4-4.

Aqueous urea solution was assumed to be the preferred, readily available and transportable source of the amine reagent needed to supply ammonia to the SCR reactor catalyst for the hypothetically-applied low-dust and tail-end SCR alternatives. A urea-to-ammonia conversion system dedicated for each SCR reactor was also assumed. This conversion process will use a natural gas-fired burner that mixes the combustion products at high temperature with the injected aqueous urea solution to thermally decompose the urea, producing gaseous ammonia to supply to the reactors' ammonia injection grids. Gaseous ammonia is the required amine reagent that the catalyst in the SCR reactors uses to convert nitrogen oxides to elemental nitrogen and water vapor. Ammonia (from urea conversion) is supplied and consumed continuously on demand while the SCR NOx reduction process is in operation. Natural gas is fired continuously during the urea-to-ammonia conversion system operation.

Final reactor inlet flue gas reheat systems are required for the hypothetical applications of tail end and low-dust SCR with ASOFA alternatives. A natural gas-fired duct burner that injects high temperature combustion products directly into the flue gas discharged from each SCR gas/gas heat exchanger was assumed for raising the reactor inlet temperature to 600ºF before ammonia injection and NOx reduction can occur in each SCR reactor. Natural gas is fired continuously for flue gas reheating during SCR system operation.

TABLE 4-10 – Energy Impacts for NO_X Control Alternatives - MRY Station Unit 2

D	Gas Reburn w/ ASOFA	0	0	6,301,740	0	6,301,740
C	Lignite Reburn w/ ASOFA	0	0	0	0	0
B	FLGR w/ ASOFA	0	0	2,610,560	0	2,610,560
A	Advanced SOFA (ASOFA)	0	0	0	0	0

(1) - Alternative label has been assigned from highest to lowest unit NOx emission rate. Alternatives are labeled the same as in Table 4-9.

(2) - The inclusion of tail-end and low-dust SCR technologies in this table does not constitute agreement that it is technically feasible to install these technologies on Unit 2 at Milton R. Young Station. The annual NOx removal and LTAC shown for a hypothetically-applied SCR system is based on assumptions that known or expected reasons for technical infeasibility for installation of the SCR equipment on this boiler are solvable. SCR technology is considered technically infeasible by Minnkota for application at MRYS per the October 2006 NO_X BACT Analysis Study report and subsequent submittals in response to comments by the NDDH, EPA, DOJ and other parties, so this information for the hypothetical application of SCR alternatives is included for comparative purposes only. See Section 4.2.1.2.1 for details of Scenario A and Scenario B that assumes replacement of SCR catalyst after a specified number of hours of unit operation.

(3) – Estimated annual natural gas usage for urea-to-ammonia conversion based on adjustments to preliminary budgetary equipment vendor proposals and process calculations. TESCR and LDSCR rate = 3.15 mmBtu/hr for each reactor x 2.

(4) – Estimated annual natural gas usage for flue gas final reheat based on adjustments to preliminary vendor process calculations. TESCR rate = 48.11 mmBtu/hr for each reactor x 2; LDSCR rate = 45.55 mmBtu/hr for each reactor x 2.

(5) – Natural gas burned for reburn alternatives is assumed to replace coal, no boiler heat rate penalty assumed. Lignite reburn is assumed to burn the same total amount of coal in the boiler as without coal reburn.

(6) - Additional coal burned is due to the urea dilution water injected directly into the boiler’s upper furnace, decreasing heat available for steam production and electricity generation, at a net loss of 900 Btu/lb of water for evaporation. See Appendix C3 in the 2006 NO_X BACT Analysis Study report for additional details.

(7) - Annual O&M costs include these values multiplied by the number of hours per year of operation and assume $7.98 per mmBtu for natural gas and $0.71 per mmBtu for coal.

4.2.3 ENVIRONMENTAL IMPACTS OF HYPOTHETICALLY-APPLIED SCR NO$_X$ CONTROL ALTERNATIVES FOR MRY STATION UNIT 2

Operation of the NO$_X$ control technologies on the dominant controls cost curve for potential application at the Milton R. Young Station impose direct and indirect impacts on the environment. The most pronounced direct environmental impact expected from operation of any of the NO$_X$ control options considered is the reduction of ozone and improvement in atmospheric visibility (i.e. reduced visibility impairment) downwind of the facility. Environmental impacts of previously-evaluated NO$_X$ control alternatives were described and summarized in Section 3.4.3 of the October 2006 NOx BACT Analysis Study report.[40]

There would be a favorable environmental impact from potential reduction of annual unit operating time by approximately two percent due to cyclone slag issues associated with air-staged cyclones/ASOFA system operation and by between five percent and 17 percent due to catalyst management and SCR equipment maintenance-related issues for the various low-dust and tail end SCR alternatives. The impact of fewer annual hours of operation will be to decrease the annual amount (tons) of nitrogen oxides emitted, by between approximately 0.2 percent and one percent overall compared to baseline operation. However, generation of replacement electrical power at other powerplants will negate most of these emission reductions.

Operation of the hypothetical application of SCR systems is not expected to significantly impact emissions of carbon monoxide (CO) or volatile organic compounds (VOCs). Emissions from the urea-to-ammonia conversion and flue gas reheat natural gas-fired burners are additive and included in the flue gas entering the SCR reactor in each hypothetical case.

Operation of any SCR system will normally cause a small amount of unreacted ammonia to be emitted. The amount of ammonia slip produced by an SCR depends on the reagent utilization and the location of the injection points. Higher SCR NO$_X$ reduction performance involves greater amounts of reagent usage and ammonia slip. This is typically controlled to less than 2 ppmvd, especially when the possible formation of sulfates such as ammonium sulfate [$(NH_4)_2SO_4$] and ammonium bisulfate [NH_4HSO_4] will be more problematic at higher slip levels. Sulfur trioxide (SO_3) formed during combustion in the boiler can combine with ammonia during passage through the catalyst to form the sulfates downstream.

---

[40] Ibid Reference number 3, October 2006, pages 3-35 through 3-37.

Unreacted ammonia (“slip”) from SCR operation will not be collected downstream of the hypothetically-applied tail end SCR reactors. The wet flue gas desulfurization absorbers downstream of the hypothetically-applied low-dust SCR reactors may reduce ammonia slip. Any remaining ammonia slip that is not collected or condensed in the air pollution control system will be emitted from the stack as an aerosol or condensable particulate. This has the potential to increase atmospheric visibility impairment downwind of the facility compared with a pristine condition.

Sulfur dioxide (SO_2) formed during combustion in the boiler can combine with oxygen during passage through the hypothetical tail end and low-dust SCR catalyst to form additional sulfur trioxide (SO_3) emissions. SO_3 can subsequently combine with water (H_2O) to form sulfuric acid (H_2SO_4), usually in the form of a mist. Wet flue gas scrubbing to remove SO_2 is not highly effective in removing SO_3 created in an upstream low-dust SCR, so higher sulfate emissions will result unless a precipitating reaction with ammonia or condensation in the downstream gas-gas reheater or ductwork occurs. SO_3 and H_2SO_4 can have significant negative far-field impairment impacts on atmospheric visibility if they are above threshold concentrations and not controlled. Tail end SCRs can also cause a small amount of SO_3 to be created as the remaining SO_2 not removed by the wet lime flue gas desulfurization systems will pass through the catalyst and some will be oxidized. It is not known whether the high concentration of alkalinity in the form of sodium aerosol particles at MRYS will effectively eliminate the remaining SO_3 downstream of the hypothetically-applied low-dust and tail end SCR systems.

Catalyst from the hypothetical application of SCR reactors will require regular replacement, requiring disposal of the spent catalyst materials or chemical cleaning to remove deposits to allow reuse or regeneration. Hauling spent catalyst to a catalyst rejuvenation facility or authorized landfill may be required, producing additional liquid and solid wastes and vehicle exhaust emissions.

Because railroad service is not available to MRYS, shipments of amine reagent (concentrated urea solution) for consumption by the hypothetical application of SCR reactors will require additional truck traffic between the supply facility and plant, producing more emissions from vehicle exhaust.

4.2.4 SUMMARY OF ECONOMIC, ENERGY AND ENVIRONMENTAL IMPACTS OF HYPOTHETICALLY-APPLIED SCR NO_X CONTROL ALTERNATIVES FOR MRY STATION UNIT 2

The economic, energy, and environmental impacts of each NO_X control technology on the dominant controls cost curve for potential application at the Milton R. Young Station evaluated for this study are summarized in this Section. Table 3-18 summarized the various impacts discussed in Sections 3.4.1 through 3.4.3 of the October 2006 NO_X BACT Analysis Study report[41]. The economic analysis examined the estimated capital cost of four hypothetically-applied SCR cases and previously-analyzed feasible NO_X control alternatives and any other powerplant upgrade costs necessary to implement the alternatives. In addition, the economic analysis examined the operating and maintenance costs associated with each NO_X control technology evaluated. These costs were then combined into the levelized total annual cost for a comparative assessment of the total implementation cost of each alternative. Finally, as part of the top-down analysis, a dominant controls cost curve was plotted and the unit control cost for each remaining alternative was evaluated. Four hypothetically-applied SCR cases and two previously-analyzed feasible alternatives were on the dominant controls cost curve and the latter were identified as the more cost-effective alternatives. The four hypothetically-applied SCR cases and two previously-analyzed feasible BACT NO_X control alternatives were evaluated for incremental cost, energy, and environmental impacts applicable to Milton R. Young Station Unit 2. The results are summarized in Tables 4-11SA and 4-11SF.

The unit control cost for the hypothetically-applied SCR cases:

- Tail End SCR w/ ASOFA stand alone SCR projects cases - Scenario A was \$4,648/ton and Scenario B was \$ 6,597/ton.
- Low-Dust SCR w/ ASOFA stand alone SCR projects cases - Scenario A was \$4,029/ton and Scenario B was \$5,946/ton.
- Tail End SCR w/ ASOFA shared facilities SCR projects cases - Scenario A was \$4,477/ton and Scenario B was \$ 6,427/ton.
- Low-Dust SCR w/ ASOFA shared facilities SCR projects cases - Scenario A was \$3,859/ton and Scenario B was \$5,777/ton.

These UCCs are approximately 370 to 525 percent of the UCC for SNCR w/ ASOFA (\$1,240/ton), and approximately 645 to 920 percent of ASOFA's UCC (\$709/ton).

---

[41] Ibid Reference number 3, October 2006, pages 3-20 through 3-38.

The incremental cost analysis indicates that from a cost effectiveness viewpoint, the SNCR with ASOFA alternative for MRYS Unit 2 incurs a significant annual (levelized) incremental cost compared to the ASOFA NO_X control technique. The slope from zero (baseline) to ASOFA (Point A) was $709/ton; the incremental cost per ton (slope) from ASOFA (Point A) to SNCR with ASOFA (Point E) was $2,263/ton for MRYS Unit 2. The incremental cost per ton (slope) from SNCR with ASOFA (Point E) to the various hypothetically-applied SCR cases:

- Tail End SCR w/ ASOFA stand alone SCR projects cases - Scenario A was $10,472/ton and Scenario B was $15,550/ton.
- Low-Dust SCR w/ ASOFA stand alone SCR projects cases - Scenario A was $8,792/ton and Scenario B was $13,812/ton.
- Tail End SCR w/ ASOFA shared facilities SCR projects cases - Scenario A was $10,007/ton and Scenario B was $15,096/ton.
- Low-Dust SCR w/ ASOFA shared facilities SCR projects cases - Scenario A was $8,331/ton and Scenario B was $13,361/ton.

The incremental unit control cost per ton (slope) from SNCR with ASOFA to the hypothetically-applied SCR with ASOFA cases are approximately 360 to 680 percent of the incremental UCC per ton (slope) between ASOFA and SNCR with ASOFA ($2,263/ton). The incremental UCCs from SNCR with ASOFA to the hypothetically-applied SCR with ASOFA cases is between 11 and 22 times the incremental UCC for ASOFA from the pre-control baseline ($709/ton).

In the U.S. EPA's NSR Manual, the EPA does not specify acceptable or unacceptable ranges for average (unit control costs) and incremental cost effectiveness values. EPA's NSR Manual however, does specifically address the standard to be used when rejecting a candidate technology on the basis of adverse economic impact:

> "Consequently, where unusual factors exist that result in cost/economic impacts beyond the range normally incurred by other sources in that category, the technology can be eliminated provided the applicant has adequately identified the circumstances, including the cost or other analyses, that show what is significantly different about the proposed source."[42]

This supplemental report for the MRYS NOx BACT Analysis has clearly established the circumstances, including the economic impacts, which would make the hypothetical application of TESCR or LDSCR to

---

[42] Ibid Reference number 2, Section IV.D.2.c.

MRYS Unit 2 significantly more expensive than SCR costs normally incurred by other coal-fired steam electric generating units. The following information further supports EPA's own statements regarding the costs "normally incurred by other sources".

The EPA's technical support document issued with the final Regional Haze Regulations and BART Guidelines was considered relevant for control cost-effectiveness comparison. The EPA's cost-effectiveness analysis used for establishing presumptive BART stated that "applying SCR for coal-fired cyclone units is typically less than $1500 a ton, and that the average cost-effectiveness is $900 per ton" [43]. EPA's Technical Support Document estimated an average control cost for SCR applied to MRYS Unit 2 of $537 per ton[44]. The unadjusted unit capital cost factor assumed by the EPA for SCR retrofits applied to cyclone boilers in the cost-effectiveness analysis used for establishing presumptive BART[45] was $100/kW. The estimated "stand alone" and "shared facilities" installed capital costs for the hypothetically-applied low-dust SCR w/ ASOFA cases at MRYS Unit 2 are $525 to $568/kW, which are more than 500 percent of the EPA's number. The estimated "stand alone" and "shared facilities" installed capital costs for the hypothetically-applied tail end SCR w/ ASOFA cases are $671 to 714/kW, which are approximately 700 percent of the EPA's number. Also stated in the final RHR/BART Guidelines, "the average cost for each [of two options, A and B]… may be deemed to be reasonable. However, the incremental cost…of the additional emissions reductions to be achieved by control B may be very great. In such an instance, it may be inappropriate to chose control B, based on its higher incremental costs, even though its average cost may be considered reasonable".[46]

4.2.5 CONCLUSIONS

The site-specific control costs estimated for application of hypothetically-applied tail-end and low-dust SCR alternatives to MRYS Unit 2 are significantly higher than the EPA's cost-effectiveness analysis for conventional SCR technologies included in the technical support document issued with the final Regional Haze Regulations and BART Guidelines discussed above.

The expected severity of catalyst blinding and pluggage from particulate matter and flue gases emitted from cyclone-fired boilers burning North Dakota lignite precludes the technical feasibility for successful application of such SCR technologies on the electric generating units (EGUs) at the Milton R. Young

Station. Not withstanding the technical discussion of SCR technology infeasibility and technical details previously provided in Appendix A1 and Appendix B[47] of the initial NO_X BACT Analysis Study report and subsequent submittals in response to comments by the NDDH, EPA, DOJ, and other parties, this supplemental analysis concludes that the estimated capital and O&M costs for four variations of hypothetically-applied tail-end and low-dust SCR technology alternatives are significantly beyond the cost analysis values included in EPA's technical support document issued with the final Regional Haze Regulations and BART Guidelines[48,49]. Average control cost effectiveness for each hypothetically-applied SCR control technology case is a minimum of approximately three times the unit control costs of the previously-analyzed highest-performing feasible control alternative recommended as BACT for MRYS Unit 2 (SNCR with ASOFA). Incremental control cost effectiveness for each hypothetically-applied SCR control technology case is a minimum of approximately three times the incremental control costs of the previously-analyzed highest-performing feasible control alternative recommended as BACT for MRYS Unit 2 (SNCR with ASOFA).

There is an expected decrease in net capacity and availability to generate electrical power due to the hypothetically-applied SCR alternatives. A 5 to 17 percent decrease in the number of hours of annual operation, and approximately 3% drop in annual plant capacity (net electrical output or MW_n) during operation of the MRYS Unit 2 system are expected if the hypothetically-applied low-dust or tail end SCR alternatives were installed. There are also substantial expected negative energy impacts for each hypothetically-applied SCR control technology case. Additional auxiliary electrical power demands of approximately 12 to 15 MW will result. This estimate of electrical power usage may be too low. This higher electrical power consumption and lower electrical power generation by MRYS Unit 2 will require additional replacement electrical power to be generated elsewhere.

Natural gas is fired continuously during the urea-to-ammonia conversion system operation for each of the hypothetically-applied Tail End and Low-Dust SCR with ASOFA alternatives.

Final reactor inlet flue gas reheat systems are required for the hypothetically-applied Tail End and Low-Dust SCR with ASOFA alternatives. Natural gas is fired continuously for flue gas reheating during SCR

system operation for raising the reactor inlet temperature to 600ºF before ammonia injection and NOx reduction can occur in each SCR reactor.

The site-specific control costs estimated for application of hypothetically-applied tail-end and low-dust SCR alternatives to MRYS Unit 2 are significantly higher than the EPA's cost-effectiveness analysis for conventional SCR technologies included in the technical support document issued with the final Regional Haze Regulations and BART Guidelines[50]. Low-dust and tail end SCR technologies should be excluded from consideration for NO_X control at MRYS due to unacceptably high average and incremental cost per ton of pollutant removal based on the supplemental analysis provided herein. Therefore the conclusions regarding NOx BACT as expressed in the original October 2006 BACT Analysis for MRYS Unit 2 are confirmed.

The economic, energy, and environmental impacts of each NO_X control technology on the dominant controls cost curve for potential application to Unit 2 at the Milton R. Young Station evaluated for this study are summarized in Tables 4-11SA and 4-11SF.

L2	Hypothetical Low-Dust SCR w/ ASOFA – Scenario A(10)	0.049	239	931	14,862	270,785	29,048	59,881	4,029	8,792	12,389	278,010,746	Flyash UBC, catalyst disposal	CO, NH_3, SO3
L1	Hypothetical Low-Dust SCR w/ ASOFA – Scenario B(10)	0.049	239	913	14,980	270,785	52,424	89,072	5,946	13,812	12,389	701,122,255	Flyash UBC, catalyst disposal	CO, NH_3, SO3
E	SNCR w/ ASOFA	0.330	1,612	6,421	9,372	17,128	8,108	11,618	1,240	2,263	133	111,184,869	Flyash UBC	CO, NH_3
A	Advanced SOFA (ASOFA)	0.489	2,391	9,621	6,172	10,008	2,805	4,376	709	709	1	75,867,520	Flyash UBC	CO
	Baseline	0.786	3,839	15,793	0	0	0	0						

(1) - Alternative label has been assigned from highest to lowest unit NOx emission rate.

(2) - Estimated NO_X control level reductions relative to average annual emission baseline of 0.786 lb/mmBtu at 4,885 mmBtu/hr heat input. Emissions are calculated from unit emission rates, control percentage, hourly heat input, and annual hrs/yr operation compared to pre-control baseline based on annual operation at a gross unit electrical output of 440 MWg and assumes a 93.9% average annual availability.

(3) - Installed capital cost is estimated for determination of total capital cost for a particular technology or combination, assuming 477 MWg unit capacity rating. All cost figures in 2006 dollars.

(4) - Annual operating and maintenance cost for a particular technology or combination is compared to unit baseline operation at a gross unit electrical output of 440 MWg and assumes a 95.2% average annual availability, which is the highest consecutive 12-months of operation from 2001-2005. All cost figures in 2006 dollars.

(5) - Levelized Total Annual Cost = Annualized Installed Capital Cost + Levelized Annual O&M cost. Annualized capital cost = Installed capital cost x 0.08718 annualized capital cost factor. Levelized annual O&M cost = Annual O&M cost x 1.24873 annualized O&M cost factor.

(6) - Average Control Cost Effectiveness ($/ton) is the Levelized Total Annual Cost (1000$/yr) divided by Annual Emission Reduction (tons/yr). All cost figures in 2006 dollars.

(7) - Incremental Control Cost Effectiveness ($/ton) is the difference in LTAC between the next most stringent alternative divided by the emissions reduction. All cost figures in 2006 dollars.

(8) - Energy impacts are incremental auxiliary electrical power demand (kW) and annual power usage plus generation lost due to negative unit availability (fewer hours per year of operation) resulting from each control alternative (kW-hrs/yr) compared to the pre-control baseline.

(9) - Environmental impacts summarize expected non-air effects and potential toxic air emissions resulting from control alternative compared to the pre-control baseline. Flyash unburned carbon content may increase with air-staging cyclones; carbon monoxide concentrations may increase an insignificant amount with air-staging cyclones. Excess unreacted ammonia (slip) expected from SNCR technology and the hypothetically-applied SCR technology cases.

(10) - The inclusion of tail-end and low-dust SCR technologies in this table does not constitute agreement that it is technically feasible to install these technologies on Unit 2 at Milton R. Young Station. The estimated annual NOx removal and LTAC shown for a hypothetically-applied SCR system is based on assumptions that known or expected reasons for technical infeasibility for installation and operation and maintenance of the SCR equipment on this boiler are solvable. SCR technology is considered technically infeasible by Minnkota for application at MRYS per the October 2006 NO_X BACT Analysis Study report and subsequent submittals in response to comments by the NDDH, EPA, DOJ and other parties, so this information for the hypothetical application of SCR alternatives is included for comparative purposes only. See Section 4.2.1.2.1 for details of Scenario A and Scenario B that assumes replacement of SCR catalyst after a specified number of hours of unit operation.

4.0 SUPPLEMENTAL NOx BACT ANALYSIS CONTROLS & COSTS – MRY STATION UNIT 1

This supplement to the NO_X BACT analysis for Milton R. Young Station (MRYS) Unit 1 has been prepared in response to the request of the North Dakota Department of Health[1]. The NDDH requested completion of a "full" BACT analysis for two specific technologies that had been eliminated at step 2 of the BACT analysis process[2] in the October 2006 NO_X BACT Analysis Study report[3]. These two technologies are low-dust selective catalytic reduction (SCR) and tail-end SCR. The approach taken in this supplemental NO_X BACT Analysis Study report for MRYS Unit 1 includes ranking by effectiveness and providing an impacts analysis of alternate control technologies for NO_X emissions that follows the third and fourth steps of a "top down" BACT analysis as described in the EPA's Draft New Source Review Workshop Manual[4]. The initial NO_X BACT Analysis Study for Milton R. Young Station identified potentially available NO_X control techniques and technologies, summarized in Table 3-3[5] of the October 2006 report. Commonly-applied and novel NO_X control techniques and technologies, including a technical description of the specific emission reduction processes and capabilities, were summarized in Section 3.2[6] and detailed in Appendix A1 of the initial NO_X BACT Analysis Study report. This supplemental analysis report does not include the details of the technical feasibility discussion previously provided in the initial NO_X BACT Analysis Study report for MRYS Unit 1.

SCR technology is considered technically infeasible by Minnkota for application at MRYS, so this information for the hypothetical application of low-dust and tail end SCR alternatives is included for comparative purposes only. Cost estimates and emission rates shown for such hypothetically-applied SCR systems are based on assumptions that known or expected reasons for technical infeasibility for installation, operation and maintenance of the SCR equipment on this boiler are solvable. There is no available information on recently-completed similar tail-end or low-dust SCR projects on coal-fired powerplants in the United States that could be used, with adjustments, to represent total installed costs that could be expected for MRYS Unit 1. Site-specific needs and challenges identified for applying tail end and low-dust SCR technologies to Milton R. Young Station Unit 1 significantly influence the capital cost estimate for variations of these hypothetical applications of SCR alternatives. Furthermore, the

[2] As described in the EPA's Draft New Source Review Workshop Manual. See Reference number 2, October 1990.
[3] See Reference number 3, October 2006. This Supplement commences with Section 4.0, which places it at the end of the October 2006 Analysis, which ended at Section 3.5.2.
[4] As described in the EPA's Draft New Source Review Workshop Manual. Ibid Reference number 2, October 1990.
[5] Ibid Reference number 3, October 2006, page 3-5.
[6] Ibid Reference number 3, October 2006, page 3-6 through page 3-13, and pages A1-1 through A1-55.

"EPA Air Pollution Control Cost Manual" is not applicable for use in estimating control equipment costs for these hypothetical applications of SCR technologies, as the EPA Control Cost Manual states:

> "The costs for the tail-end arrangement, however, cannot be estimated from this report because they are significantly higher than the high-dust SCR systems due to flue gas reheating requirements."[7]

This requirement for flue gas reheating also applies to the hypothetical application of low-dust SCR to MRYS, due to the cold-side arrangement (downstream of the electrostatic precipitator) instead of a hot-side ESP assumed in the EPA Control Cost Manual. Therefore, the equations in the EPA Control Cost Manual cannot be used for estimating either of the hypothetical applications of SCR configurations for which NDDH has requested economic analyses. Thus it was necessary to prepare independent site-specific cost estimates.

The site-specific control costs estimated for hypothetical application of tail-end and low-dust SCR alternatives to MRYS Unit 1 are significantly higher than the EPA's cost-effectiveness analysis for conventional SCR technologies included in the technical support document issued with the final Regional Haze Regulations and BART Guidelines[8]. Low-dust and tail end SCR technologies should be excluded from consideration for NO_X control at MRYS due to unacceptably high average and incremental cost per ton of pollutant removal based on the supplemental analysis provided herein. The October 2006 NO_X BACT Analysis Study report, and additional subsequent arguments included in responses to comments by the EPA, Department of Justice (DOJ), NDDH, and other parties[9], also present reasons for technical infeasibility of all SCR technologies considered for application at MRYS not included in this supplemental analysis report. In addition, the fact that catalyst vendors will not guarantee catalyst life on such SCR technologies without successful results from extensive pilot slipstream testing bolsters the previous submitted arguments of technical infeasibility of these NO_X control alternatives at MRYS.

4.0.1 ADDITIONAL NOx CONTROLS

The inclusion of hypothetical emissions control alternatives employing tail-end and low-dust SCR technologies in this supplemental NO_X BACT Analysis Study report does not constitute agreement by

---

[7] See Reference number 10, Section 4.2, Chapter 2, page 2-41, October 2000.
[8] See Reference number 4, June, 2005.
[9] Responses submitted by Minnkota in 2007-2009.

Minnkota that it is technically feasible to install these technologies on Unit 1 at Milton R. Young Station. The rationale for rejection of all forms of SCR technology in this specific case, based on an interpretation of the EPA's Draft New Source Review Workshop Manual[10], has previously been submitted to the North Dakota Department of Health[11] and is not repeated herein. Nevertheless, this supplemental NO_X BACT Analysis Study report has been completed based on the *hypothetical assumption* that these two technologies pass the test for technical feasibility. The development of NO_X emissions control alternatives involving hypothetical application of technologies such as low-dust and tail end SCR systems at MRYS is based on preliminary plant layout design concepts that require pilot-scale slipstream SCR testing and more detailed equipment design for confirmation that all technical infeasibility issues previously raised have been, or can be, satisfactorily resolved. This supplemental analysis includes estimated capital costs and operating and maintenance (O&M) costs for four variations of alternatives involving hypothetical applications of tail-end and low-dust SCR technologies. Cost effectiveness for each hypothetically-applied SCR control technology case was plotted with previously-analyzed feasible control alternatives.

For the techniques and technologies considered for determining MRYS Unit 1 NO_X control cost-effectiveness, estimates were produced for predicted NO_X reductions that represent long-term expectations of the reduction techniques and technologies being presented in the technical analysis. Each evaluated alternative was tabulated and graphed.

It should be noted that as of October 2006, when the initial BACT Analysis Study report was completed, MRYS Unit 1 did not employ combustion-related or post-combustion NO_X emission reduction technology. However, the installation of an advanced form of a separated overfire air system (ASOFA), designed specifically for this boiler, is being implemented for operation starting prior to December 31, 2009. A summary of the available alternate NO_X emission control technologies is discussed below.

4.1 RANK OF NO_X CONTROL OPTIONS BY EFFECTIVENESS

The first step[12] in this supplemental "top-down" BACT evaluation is to determine the expected control effectiveness of the hypothetical application of tail end and low-dust SCR technology alternatives, so that they may be compared and ranked relative to the technically-feasible NO_X control techniques and

---

[10] Ibid Reference number 2, October 1990.
[11] See Reference number 5, November 2007.
[12] Step 3 per the NSR Manual, Ibid Reference 2, October 1990.

technologies included from the initial NO_X BACT Analysis Study report. To do this, we start with the basis for determining the NOx emissions control effectiveness, which is the historic baseline emissions expressed in pounds per million Btu of heat input from the five-year lookback period.

Unit 1 boiler's baseline pre-control emissions at Milton R. Young Station are based upon the same highest rolling 12-month average unit emission rate (lb/mmBtu) and corresponding highest rolling 12-month average gross heat input rate (mmBtu/hr) that were reported in 2001-2005:

- MRYS Unit 1's highest 12-month NO_X mass emissions averaged 0.849 lb/mmBtu at a corresponding average unit heat input rate of 2,744 mmBtu/hr and unit gross electrical output of 244.5 MW_g.
- During this lookback time period, Unit 1 at Milton R. Young Station was typically operated in a base-loaded manner.

4.1.1 ESTIMATING CONTROL-EFFECTIVENESS OF NO_X EMISSIONS CONTROL OPTIONS

The estimated emission control performance for NO_X control techniques and technologies included from the initial NO_X BACT Analysis Study report is assumed to be the same as previously stated in Table 3-7[13]. The expected control effectiveness of the hypothetical application of tail end and low-dust SCR technology alternatives was added to the listing of highest-performing NO_X control alternatives remaining in consideration following the initial technical infeasibility determinations. These alternatives are ranked in declining order of expected emission reduction. These combined control options refer to "advanced" separated overfire air (ASOFA), and include the expected reduction from operating with modestly air-staged cyclone furnaces and relocated lignite drying system vent ports as applied to this Milton R. Young Station cyclone boiler without incurring potential significant negative impacts of this technique. This level of expected NO_X reduction from ASOFA operation is approximately forty percent below the pre-control baseline emissions rate of 0.849 lb/mmBtu.

---

[13] Ibid Reference number 3, October 2006, page 3-18.

TABLE 4-1 – Ranked NO_X Control Options for MRY Station Unit 1 Boiler with Expected Control Performance

Alt. Label[1]	NO_X Control Alternative	Emission Rate (lb/mmBtu)	Control Percentage[2]
T2	Hypothetical Tail-End SCR w/ ASOFA – Scenario A[3]	0.053	93.8[4]
T1	Hypothetical Tail-End SCR w/ ASOFA – Scenario B[3]	0.053	93.8[4]
L2	Hypothetical Low-Dust SCR w/ ASOFA – Scenario A[3]	0.053	93.8[4]
L1	Hypothetical Low-Dust SCR w/ ASOFA – Scenario B[3]	0.053	93.8[4]
E	SNCR (using urea) w/ ASOFA	0.355	58.1
D	Gas Reburn with ASOFA	0.374	56.0
C	Lignite Reburn w/ ASOFA	0.385	54.6
B	Fuel Lean Gas Reburn with ASOFA	0.460	45.9
A	Advanced Separated Overfire Air (ASOFA)	0.513	39.5
-	Baseline	0.849	-

(1) - Alternative designation assigned from highest to lowest unit NOx emission rate.

(2) - Control percentages are relative to an average pre-control emission baseline of 0.849 lb/mmBtu based on annual operation at highest pre-control 12-month rolling NOx summation mass emissions divided by the 12-month heat input summation.

(3) - The inclusion of tail-end and low dust SCR technologies in this table does not constitute agreement that it is technically feasible to install these technologies on Unit 1 at Milton R. Young Station. The emission rate shown for a hypothetically-applied SCR system is based on assumptions that known or expected reasons for technical infeasibility for installation of the SCR equipment on this boiler are solvable. SCR technology is considered technically infeasible by Minnkota for application at MRYS per the October 2006 NOx BACT Analysis Study report and subsequent submittals in response to comments by the NDDH, EPA, DOJ, and other parties, so this information for the hypothetical application of SCR alternatives is included for comparative purposes only. See Section 4.2.1.2.1 for details of Scenario A and Scenario B that assumes replacement of SCR catalyst after a specified number of hours of unit operation.

(4) The stated overall control percentage includes the anticipated long-term emission reduction of 90% design removal from a baseline of 0.51 lb/mmBtu resulting from an advanced separated overfire air system, with air-staged low-NO_X cyclone combustion. Without a separated overfire air system operation or any other technique employed, the assumed emission rate for hypothetically-applied SCR alternatives would be 0.085 lb/mmBtu, for an overall reduction of 90 percent from a baseline of 0.849 lb/mmBtu.

All hypothetical applications of tail-end and low-dust SCR technology alternatives were assumed to achieve a NO_X emission level of 0.053 lb/mmBtu, which is approximately 90% reduction from a 0.51 lb/mmBtu level representing ASOFA when operating modestly air-staged cyclone furnaces with suitable combustion controls.

Hourly mass emission rates for the baseline pre-control condition were calculated by multiplying the unit emission rate (lb/mmBtu) by the average hourly gross heat input rate (mmBtu/hr), both calculated from Unit 1’s highest 12-month NO_X mass emissions and heat inputs during the 5-year lookback period.

Equivalent annual NO_X emissions (tons) were calculated by multiplying the 12-month summation for unit operating hours during the same period as the highest NO_X emissions by the 12-month average mass emission rate (lb/hr) and dividing by 2000 lb/ton.

The annual tons for the control options were calculated by multiplying the alternative's equivalent average annual hourly mass emission rate (lb/h) by the equivalent annual unit operating hours [8,760 h/yr maximum possible operating time, adjusted by an annual uptime (availability) factor]. Scheduled and unplanned maintenance outages are expected to occur due to each hypothetically-applied SCR system. Catalyst cleaning and replacement events have been estimated, with two frequencies showing a range of possible results. Due to the variability and possible severity of fouling characteristics of gaseous and aerosol particulate emissions generated by cyclone combustion of lignite supplied from the Center mine, and the dependency of the fouling within the hypothetically-applied SCR systems on sodium, potassium, sulfur, and ammonia slip emission levels, conditions may occur during operation of the hypothetically-applied SCR systems that exceed the ability to adjust operational practices sufficiently to avoid forced outages to remove the deposits or prevent significant catalyst deactivation. Table C.4-1 in Section 4.2.1.2.1 includes estimated unit availability and corresponding operating time and outage time due to the four hypothetical applications of SCR technology cases, along with the ASOFA and baseline numbers from the referenced Appendix C3 of the initial NO_X BACT Analysis Study report[14]. Based on these calculations, the estimated annual emissions for M.R. Young Station Unit 1 and the emission reduction corresponding to each technology alternative are shown in Table 4-2.

---

[14] Ibid Reference number 3, October 2006, pages C3-1 through page C3-11.

TABLE 4-2 – Expected Annual NO_X Control Performance for MRY Station Unit 1 Alternatives

		EMISSIONS				
Alt. Label(1)	**NOx Control Alternative**	**Emission Rate lb/mmBtu**	**Hourly Emission(2) lbs/hr**	**Annual Emission(3) tons/yr**	**Emission Reduction(4) tons/yr**	**NOx Removal Efficiency(5) %**
T2	Hypothetical Tail End SCR w/ ASOFA– Scenario A(6)	0.053	145	589	9,345	93.8(7)
T1	Hypothetical Tail End SCR w/ ASOFA– Scenario B(6)	0.053	145	536	9,398	93.8(7)
L2	Hypothetical Low-Dust SCR w/ ASOFA – Scenario A(6)	0.053	145	586	9,348	93.8(7)
L1	Hypothetical Low-Dust SCR w/ ASOFA – Scenario B(6)	0.053	145	533	9,401	93.8(7)
E	SNCR (using urea) w/ ASOFA	0.355	975	4,025	5,909	58.1
D	Gas Reburn w/ ASOFA	0.374	1,025	4,275	5,659	56.0
C	Lignite Reburn w/ ASOFA	0.385	1,058	4,343	5,591	54.6
B	Fuel Lean Gas Reburn w/ ASOFA	0.460	1,261	5,260	4,674	45.9
A	Advanced Separated Overfire Air (ASOFA)	0.513	1,409	5,874	4,060	39.5
-	Baseline	0.849	2,330	9,934	0	-

(1) - Alternative label has been assigned from highest to lowest unit NOx emission rate.

(2) - Hourly NO_X emission estimates (lb/hr) were calculated based upon average annual unit emission rate (lb/mmBtu) x 2,744 mmBtu/hr heat input.

(3) - Estimated annual emission tons assume an annual unit availability factor specific to each alternative; 97.3% was assumed for the baseline case. See Appendix C3 of the October 2006 NO_X BACT Analysis Study report. Hypothetical application of tail end SCR case T2 assumes an annual unit availability factor of 92.8% (approx. 8,127 operating hours per year) and case T1 assumes an annual unit availability factor of 84.5% (approx. 7,402 operating hours per year). Hypothetically-applied low-dust SCR case L2 assumes an annual unit availability factor of 92.3% (approx. 8,084 operating hours per year) and case L1 assumes an annual unit availability factor of 84.0% (approx. 7,359 operating hours per year).

(4) - Estimated annual tons of emission reduction is the difference between annual baseline tons and each alternative's annual emissions (tons).

(5) - Estimated NO_X control level percentage reductions relative to 0.849 lb/mmBtu emission baseline at 2,744 mmBtu/hr MCR heat input.

(6) - The inclusion of tail-end and low dust SCR technologies in this table does not constitute agreement that it is technically feasible to install these technologies on Unit 1 at Milton R. Young Station. The emission rate shown for a hypothetically-applied SCR system is based on assumptions that known or expected reasons for technical infeasibility for installation and operation and maintenance of the SCR equipment on this boiler are solvable. SCR technology is considered technically infeasible by Minnkota for application at MRYS per the October 2006 NOx BACT Analysis Study report and subsequent submittals in response to comments by the NDDH, EPA, DOJ, and other parties, so this information for the hypothetical application of SCR alternatives is included for comparative purposes only. See Section 4.2.1.2.1 for details of Scenario A and Scenario B that assume replacement of SCR catalyst after a specified number of hours of unit operation.

(7) - The stated overall control percentage includes the anticipated long-term emission reduction of approximately 90% design removal from a baseline of 0.51 lb/mmBtu resulting from an advanced separated overfire air system, with air-staged low-NO_X cyclone combustion. Without a separated overfire air system operation or any other technique employed, the assumed emission rate for hypothetically-applied SCR alternatives would be 0.085 lb/mmBtu, for an overall reduction of 90 percent from a baseline of 0.849 lb/mmBtu.

4.2 NO_X CONTROLS ANALYSIS AND IMPACTS EVALUATION

The next step[15] of this supplemental "top-down" BACT analysis is to evaluate the impacts of the hypothetical application of SCR alternatives' NO_X emission controls. Energy, economic, and environmental impacts are to be considered in the control technology evaluation. The purpose of the evaluation is to determine if there are any energy, economic or environmental impacts that would eliminate the top control technologies from consideration.

This evaluation of the effectiveness of the hypothetically-applied SCR alternatives, as well as that of the other control technologies previously considered technically feasible, was performed prospectively, i.e., assuming that none of the control technologies has been implemented. This approach assumes that the hypothetical application of SCR technology cases are considered to have been added to the previous NO_X BACT Analysis Study report submitted in October, 2006. The actual costs incurred for an installed advanced separated overfire air system, or firm price equipment quotes with performance guarantees for SNCR alternatives, have not been used to adjust the control effectiveness or cost impacts of the previously analyzed control alternatives. The approach taken in this supplemental analysis use installed capital costs estimated in calendar year 2009 escalated to project completion forecast in 2018 adjusted to calendar year 2006 basis for the hypothetically-applied tail end SCR and low-dust SCR technology cases that have been added to the list of alternatives previously evaluated.

4.2.1 NO_X CONTROL ECONOMIC IMPACTS FOR MRY STATION UNIT 1

An evaluation was performed to determine the various cost impacts of installing previously-analyzed feasible NO_X control alternatives and the hypothetical application of low-dust and tail end SCR technologies on Milton R. Young Unit 1. This evaluation includes estimated:

- Capital costs;
- Fixed and variable operating and maintenance costs; and
- Levelized total annual costs

to engineer, design, procure, construct, install, startup, test, and place into commercial operation the particular control technology. The results of this evaluation are summarized in Tables 4-3 through 4-11.

---

[15] Step 4 per the NSR Manual, Ibid Reference 2, October 1990.

4.2.1.1 CAPITAL COST ESTIMATES FOR NO_X CONTROL ALTERNATIVES

The range of estimated capital costs to implement some of the various NO_X control technologies were derived from unit output capital cost factors ($/kW) published in technical papers discussing those control technologies. For MRY Station Unit 1, for the cases involving the use of advanced separated overfire air and SNCR alternatives, preliminary project cost estimates using vendor budgetary cost information were developed and used in place of, or to adjust, the published unit output cost factors. A discussion of the reburn alternatives' estimated capital costs was included in the 2006 NO_X BACT Analysis Study report and has not been repeated here. These cost estimates were considered to be study grade, which is + or – 30% accuracy.

For the hypothetical application of low-dust and tail end SCR alternatives at MRYS, there is no available information on recently-completed similar projects on coal-fired powerplants in the United States that could be used, with adjustments, to properly represent total installed costs that could be expected for MRYS Unit 1. For these alternatives, site-specific detailed preliminary (conceptual) designs were developed and budgetary cost information for major equipment was obtained for the development of the estimated installed capital cost.

The unit nameplate output capacity (gross electrical output in megawatts) assumed for the installed capital cost estimate basis of the NO_X control technologies evaluated was 257 MW_g for MRY Station Unit 1[16].

A review of the unit capital cost factor range and single point factors applicable to MRY Station Unit 1 NO_X control technologies are presented in Tables 4-3SA and 4-3SF. Note that the capital cost estimates for the hypothetical application of SCR alternatives were developed separately based on two different assumptions. In one case it was assumed that all costs for the hypothetically-applied Unit 1 SCR (tail end or low-dust) system would be accounted for as if the SCR equipment were being provided for Unit 1 only. This is referred to as the “stand alone” (SA) case, and all tables showing those costs are identified with that suffix. In the other case, it was assumed that the retrofit of hypothetically-applied SCR systems was being done for both Unit 1 and Unit 2, and there are some components that could be shared between the two units. This is referred to as the “shared facilities” (SF) case, and all tables showing those costs are identified with that suffix.

---

[16] Ibid Reference number 4, June 2005, Excel Spreadsheet OAR-2002-0076-0446, page 390.

Per the EPA's NSR Manual, a BACT analysis is done on a "case-by-case basis"[17]. The "stand alone" estimated total project capital costs for the hypothetical application of SCR alternatives reflect the economic impacts incurred as a result of implementing such technologies on each individual unit at MRYS independent of what may be determined or assumed for other units at this facility or similar units at other facilities. The "shared facilities" estimated total project capital costs for the hypothetical application of SCR alternatives do not account for all economic impacts borne strictly by the unit subject to the analysis, and, as such, are subsidized by the unit(s) involved with the shared facilities. In this "shared facilities" approach, a BACT would be performed more in the manner of a "case-within-a-case" instead of on a "case-by-case" basis. Additionally, BACT is not to be applied on a facility basis. Units having different characteristics, (size, etc.) may have different technologies as BACT. Therefore, each unit should be treated as a separate "stand alone" case. Although the authors believe the "stand alone "case is the proper approach to use, information for both cases has been provided.

TABLE 4-3SA – Unit Capital Cost Factors of NO_X Control Alternatives for MRY Station Unit 1 - Stand Alone SCR Projects

Alt. Label(1)	NO_X Control Alternative	Range(2) ($/kW)	Single Point Unit Capital Cost Factor(3), ($/kW) MRYS Unit 1
T2	Hypothetical Tail End SCR w/ ASOFA – Scenario A(4)	(4)	867(4),(5)
T1	Hypothetical Tail End SCR w/ ASOFA –Scenario B(4)	(4)	867(4),(5)
L2	Hypothetical Low-Dust SCR w/ ASOFA – Scenario A(4)	(4)	703(4),(5)
L1	Hypothetical Low-Dust SCR w/ ASOFA – Scenario B(4)	(4)	703(4),(5)
E	SNCR (using urea) w/ ASOFA	20-35(6)	31.6(5),(6)
D	Gas Reburn w/ ASOFA	15-30(7)	70.1(5),(7),(8)
C	Lignite Reburn w/ ASOFA	30-60(7)	181.5(5),(7),(9)
B	Fuel Lean Gas Reburn w/ ASOFA	--(6)	41.4(5),(6),(8)
A	Advanced Separated Overfire Air (ASOFA)	5-10(7)	16.6(5)

(1) - Alternative designation has been assigned from highest to lowest unit NOx emission rate.
(2) - Unit capital cost factors ($/kW) of these individual technologies combined by simple addition. Actual installed costs may differ from this due to positive or negative synergistic effects. Range based on published values or vendor proposals.
(3) - Single point cost factor is best estimate for determination of total capital cost for a particular technology or combination, assuming maximum unit capacity is based on EPA's nameplate rating. Single point cost figures in 2006 dollars.
(4) - The inclusion of tail-end and low dust SCR technologies in this table does not constitute agreement that it is technically feasible to install these technologies on Unit 1 at Milton R. Young Station. The single point unit capital cost factor shown for a hypothetically-applied SCR system is based on assumptions that known or expected reasons for technical

infeasibility for installation of the SCR equipment on this boiler are solvable. SCR technology is considered technically infeasible by Minnkota for application at MRYS per the October 2006 NOx BACT Analysis Study report and subsequent submittals in response to comments by the NDDH, EPA, DOJ, and other parties, so this information for the hypothetical application of SCR alternatives is included for comparative purposes only. See Section 4.2.1.2.1 for details of Scenario A and Scenario B that assume replacement of SCR catalyst after a specified number of hours of unit operation. Due to the site-specific nature of factors influencing cost, no comparable cost data ranges for these technologies exist in the literature. A cost range for conventional high-dust SCR technology published in the 2005 EPA Report "Multipollutant Emission Control Technology Options for Coal-fired Power Plants", EPA-600/R-05/034[18] was \$55 to \$150/kW. Single point unit capital cost factors were derived from Burns & McDonnell internal database and cost estimates prepared specifically for MRYS Unit 1 in 2018 dollars converted to 2006\$ as described in the text.

(5) - The single point unit capital cost factor shown for the "advanced" version of SOFA derived from Burns & McDonnell internal database and cost estimate for North Dakota lignite-fired cyclone boilers.

(6) - Estimated capital cost for SNCR point estimate and FLGR point estimate derived from December 2004 budgetary proposal by Fuel Tech. The unit capital cost factor range for FLGR applications on boilers without an existing a high-pressure natural gas supply was not found in available technical literature. See Appendix C2 of the October 2006 NO_X BACT Analysis Study report for details[19].

(7) - NESCAUM 2005 Technical Paper[20]; reburn alternatives on page 2-22, overfire air on page 2-23; posted at their website. See technical references in Appendix A1 of the October 2006 NO_X BACT Analysis Study report for details.

(8) - The single point unit capital cost factor shown for a conventional or fuel-lean gas reburn system includes the estimated capital cost to install a high-pressure natural gas supply pipeline (31.4 \$/kW or 15.7 \$/kW, respectively), and that both MRYS boilers share the capital cost in proportion to their respective rated MW gross output capacities.

(9) - The single point unit capital cost factor shown for a lignite reburn system is highly site-specific, and assumes that new pulverizers and building enclosures are required. The general cost range for pulverized coal-fired boilers is included in the NESCAUM 2005 Technical Paper; for cyclone boilers is included in the 2005 WRAP Draft Report[21], posted at their website. The single point unit capital cost factor for this alternative for increased PM collection capacity included in lignite reburn option is 91.7 \$/kW. See technical references in Appendix A1 of the October 2006 BACT Analysis report for details.

(8) - The single point unit capital cost factor shown for a conventional or fuel-lean gas reburn system includes the estimated capital cost to install a high-pressure natural gas supply pipeline (31.4 $/kW or 15.7 $/kW, respectively), and that both MRYS boilers share the capital cost in proportion to their respective rated MW gross output capacities.

(9) - The single point unit capital cost factor shown for a lignite reburn system is highly site-specific, and assumes that new pulverizers and building enclosures are required. The general cost range for pulverized coal-fired boilers is included in the NESCAUM 2005 Technical Paper; for cyclone boilers is included in the 2005 WRAP Draft Report[25], posted at their website. The single point unit capital cost factor for this alternative for increased PM collection capacity included in lignite reburn option is 91.7 $/kW. See technical references in Appendix A1 of the October 2006 BACT Analysis report for details.

4.2.1.1.1 CAPITAL COST ESTIMATES FOR HYPOTHETICAL APPLICATION OF SCR NO_X CONTROL ALTERNATIVES

There is no available information on recently-completed similar tail-end or low-dust SCR projects on coal-fired powerplants in the United States that could be used, with adjustments, to properly represent total installed costs that could be expected for MRYS Unit 1. Site-specific needs and challenges identified for applying tail end and low-dust SCR technologies to Milton R. Young Station Unit 1 significantly influence the capital cost estimate for variations of these hypothetically-applied SCR alternatives. Furthermore, the "EPA Air Pollution Control Cost Manual" is not applicable for use in estimating control equipment costs for these hypothetical applications of SCR technology cases, as the EPA Control Cost Manual states:

---

[22] See Reference number 6, March 2005, page 3-63.
[23] See Reference number 3, October 2006, pages C2-3 and C2-7.
[24] See Reference number 7, March 2005.
[25] See Reference number 8, April 2005, page 3-9.

> "The costs for the tail-end arrangement, however, cannot be estimated from this report because they are significantly higher than the high-dust SCR systems due to flue gas reheating requirements."[26]

This requirement for flue gas reheating also applies to the hypothetical applications of low-dust SCR technology to MRYS, due to the cold-side arrangement (downstream of the electrostatic precipitator) instead of a hot-side ESP assumed in the EPA Control Cost Manual. Therefore, the equations in the EPA Control Cost Manual cannot be used for estimating either of the hypothetical application of SCR configurations for which NDDH has requested economic analyses. Thus it was necessary to prepare independent site-specific cost estimates.

The installed capital costs for hypothetical application of tail end and low-dust SCR alternatives were estimated by Burns & McDonnell with inputs from an SCR system supplier with recent design experience involving these SCR configurations, equipment suppliers, and catalyst suppliers with significant European project experience in such technology. Both hypothetically-applied low-dust and tail end SCR designs for MRYS Unit 1 assume one reactor / gas reheat system installed, connecting to the new wet lime flue gas desulfurization absorber currently being constructed. Each hypothetically-applied SCR alternative includes flue gas reheat equipment that is typical for these applications but not required for conventional high-dust/hot side SCR systems. The estimated flue gas volume at a gross boiler heat input and oxygen content corresponding to unit gross nameplate output capacity determined the size of the hypothetically-applied single SCR reactor for these cases. Structures, foundations, ductwork, balance of plant equipment and materials were quantified and included with the hypothetically-applied SCR equipment, which were factored for installation costs. Escalation of project costs, including equipment, materials, engineering and labor costs, is included, along with interest during construction, due to the expected project execution duration being significantly longer than for the other alternatives. Price and scope contingencies were included to account for the uncertainties that the current preliminary design scope and pricing fully reflects what would be necessary to complete implementation of these hypothetically-applied alternatives. Total project costs were considered to be a future value from a financial perspective, which were returned to a 2009 calendar year basis using a present value factor at the 2.5% per year annual discount rate previously assumed in the 2006 NO_X BACT Analysis Study report. A ratio of regional construction cost indices for public utility construction costs between 2006 and 2009 was used to adjust the 2009 total estimated project costs to a 2006 calendar year basis for each of the hypothetically-applied SCR alternatives.

---

[26] See Reference number 10, Section 4.2, Chapter 2, page 2-41, October 2000.

The estimated installed and levelized annual capital costs for the hypothetically-applied SCR systems and previously-analyzed highest-performing form of the various feasible NO_X emission reduction technologies evaluated for cost-effectiveness are shown in Table 4-4SA and Table 4-4SF. These technologies are listed in order of control effectiveness, with the highest ranked option at the top.

TABLE 4-4SA – Estimated Capital Costs for NO_X Control Alternatives - MRY Station Unit 1 - Stand Alone SCR Projects

A	Advanced SOFA (ASOFA)	4,277	373
	Baseline	0	0

(1) - Alternative label has been assigned from highest to lowest unit NOx emission rate.

(2) - Installed capital cost is estimated for determination of total capital cost for a particular technology or combination, assuming 257 MWg unit capacity rating. All cost figures in 2006 dollars. See Table 4-5SA for presentation of installed capital costs determined for hypothetical application of SCR alternatives.

(3) - Annualized capital cost = Installed capital cost x 0.08718 annualized capital cost factor.

(4) - The inclusion of tail end and low-dust SCR technologies in this table does not constitute agreement that it is technically feasible to install these technologies on Unit 1 at Milton R. Young Station. The installed capital cost shown for a hypothetically-applied SCR system is based on assumptions that known or expected reasons for technical infeasibility for installation of the SCR equipment on this boiler are solvable. Costs are derived from Burns & McDonnell internal database and cost estimates prepared specifically for MRYS Unit 1 in 2018 dollars converted to 2006\$ as described in the text. SCR technology is considered technically infeasible by Minnkota for application at MRYS per the October 2006 NO_X BACT Analysis Study report and subsequent submittals in response to comments by the NDDH, EPA, DOJ, and other parties, so this information for the hypothetical application of SCR alternatives is included for comparative purposes only. See Section 4.2.1.2.1 for details of Scenario A and Scenario B that assumes replacement of SCR catalyst after a specified number of hours of unit operation.

(5) - Costs for gas reburn options include high-pressure natural gas supply pipeline installed capital cost of \$8,075,000 for CGR and \$4,038,000 for FLGR; and annualized capital cost of \$704,000/yr for CGR and \$352,000 for FLGR. See footnote number 8 under Table 4-3SA.

(6) - Costs for increased PM collection capacity included in lignite reburn option are \$23,561,000 for installed capital cost, and \$2,054,000/yr annualized capital cost.

See Table 4-5SF for presentation of installed capital costs determined for hypothetical application of SCR alternatives.

(3) - Annualized capital cost = Installed capital cost x 0.08718 annualized capital cost factor.

(4) - The inclusion of tail end and low-dust SCR technologies in this table does not constitute agreement that it is technically feasible to install these technologies on Unit 1 at Milton R. Young Station. The installed capital cost shown for a hypothetically-applied SCR system is based on assumptions that known or expected reasons for technical infeasibility for installation of the SCR equipment on this boiler are solvable. Costs are derived from Burns & McDonnell internal database and cost estimates prepared specifically for MRYS Unit 1 in 2018 dollars converted to 2006$ as described in the text. SCR technology is considered technically infeasible by Minnkota for application at MRYS per the October 2006 NO_X BACT Analysis Study report and subsequent submittals in response to comments by the NDDH, EPA, DOJ, and other parties, so this information for the hypothetical application of SCR alternatives is included for comparative purposes only. See Section 4.2.1.2.1 for details of Scenario A and Scenario B that assumes replacement of SCR catalyst after a specified number of hours of unit operation.

(5) - Costs for gas reburn options include high-pressure natural gas supply pipeline installed capital cost of $8,075,000 for CGR and $4,038,000 for FLGR; and annualized capital cost of $704,000/yr for CGR and $352,000 for FLGR. See footnote number 8 under Table 4-3SF.

(6) - Costs for increased PM collection capacity included in lignite reburn option are $23,561,000 for installed capital cost, and $2,054,000/yr annualized capital cost.

The Total Project Costs estimated for tail end and low-dust SCR technologies hypothetically applied to MRYS Unit 1 are shown in Table 4-5SA and Table 4-5SF in 2018, 2009, and 2006 dollars.

The estimated installed capital costs for the hypothetical application of tail end or low-dust SCR system retrofits on MRYS Unit 1 included the following equipment and components:

- One SCR reactor utilizing a “3 +1” arrangement of catalyst layers, in which three layers of catalyst are initially installed, and space for installation of a fourth layer is provided.
- Sootblowers for each catalyst layer to maintain cleanliness of catalyst
- Flue gas reheat equipment that is typical for these applications but not required for conventional high-dust/hot side SCRs. This reheat equipment includes rotary regenerative heat exchangers (gas-to-gas heaters [GGH]) and natural gas-fired duct burners.
- Underground high-pressure natural gas supply pipeline and pressure regulators and metering equipment
- Hot air recirculation and heating equipment to maintain catalyst in a warm and dry condition during standby periods
- Induced draft booster fan and dampers
- Interconnecting ductwork
- SCR bypass duct and dampers (used during times the boiler is off-line)
- Storage tanks, building, and equipment for unloading and preparation of liquid urea solution
- Circulation pumps and piping for urea solution
- Urea-to-ammonia thermal conversion with urea conversion, metering, atomization, and injection equipment
- Ammonia gas dilution/combustion air fans and burners for natural gas-firing to decompose the urea solution to ammonia
- Service and sootblowing air compressors with dryers
- Electrical motor control centers
- Controls and instrumentation
- Reinforced concrete foundations
- Active coal yard storage modifications to regain lost live capacity and handling equipment due to space consumed by the SCR reactor structures
- Installation labor, materials, and management.

Addition of new electrical loads to the existing plant facilities will be required for the reagent system and new induced draft booster fan power consumption. Based on recent plant electrical distribution equipment installations, additional plant auxiliary electrical power will be available for powering the new hypothetically-applied SCR equipment. Confirmation of these concepts and cost estimates prior to any subsequent plans for implementation requires successful completion of extensive pilot-scale slipstream

testing, and more detailed plant layout and equipment design than has been performed as part of this supplemental update to the October 2006 NO_X BACT Analysis Study report.

The capital cost estimated individually for an ASOFA system retrofit on MRYS Unit 1 as previously described in the initial NO_X BACT Analysis Study report was simply arithmetically added to the hypothetical application of SCR alternatives' capital cost estimates.

4.2.1.2 O&M COST ESTIMATES FOR NO$_X$ CONTROL ALTERNATIVES

Operational costs to implement the hypothetical application of SCR alternatives and previously-analyzed feasible NO$_X$ control alternatives for Milton R. Young Unit 1 were estimated using preliminary conceptual designs and budgetary vendor quotes in place of, or to adjust, the OAQPS cost factors established in the EPA's Air Pollution Control Cost Manual (OAQPS) for SNCR[27] and SCR[28], and using other costs published in technical papers discussing those control technologies. Maintenance costs were estimated as

---

[27] See Reference number 9, October 2000.
[28] See Reference number 10, October 2000.

percentages of installed capital costs, with additional catalyst replacement costs using budgetary vendor quotes based on preliminary conceptual designs and expected design life.

Fixed and variable operating and maintenance costs considered and included in each NO_X control technology's annual O&M costs are estimates of:

- Auxiliary electrical power consumption (megawatt-hours) and incremental purchased power unit costs for operating the additional control equipment;
- Natural gas consumption and unit cost for hypothetical application of SCR alternatives' flue gas reheating and urea-to-ammonia thermal conversion systems and feasible fuel reburn alternatives;
- Reagent consumption and reagent unit cost for hypothetical application of SCR alternatives and feasible SNCR alternatives;
- Reagent dilution water consumption and unit cost for SNCR alternatives.
- Catalyst removal and replacement for hypothetical application of SCR alternatives.
- Increases or savings in auxiliary electrical power consumption for changes in coal preparation equipment and loading, primarily for fuel reburn cases;
- General operating labor, plus maintenance labor and materials devoted to the additional emission control equipment and its impact on existing boiler and plant equipment;
- Costs for purchase of replacement electrical power expected to result from loss of unit availability, i.e., outages attributable to the control option which reduce annual net electrical generation available for distribution.

For economic evaluation purposes, a 12-month rolling average running plant capacity factor of 96.6 percent (based on a historic (demonstrated) sustainable unit output capacity of 253 MW_g) combined with a 12-month rolling average availability (uptime) of 8,528 operating hours (97.3 percent of 8760 hours per year) resulting in an equivalent annual average unit capacity factor of 94.1% was assumed for Unit 1's pre-control baseline annual operation. A 12-month rolling average heat input rate of 2,744 mmBtu/hr and a 12-month rolling average NO_X emission rate of 0.849 lb/mmBtu from pre-control maximum rolling 12 month summation of nitrogen oxides mass emissions were assumed for calculating equivalent annual average control and cost-effectiveness for MRY Station Unit 1.

Tables 4-6SA and 4-6SF show the estimated annual operating and maintenance costs and levelized annual O&M cost values for the hypothetically-applied SCR alternative cases and the highest-performing form of previously-evaluated feasible NO_X emission reduction technologies. These are listed in order of control effectiveness, with the highest ranked options at the top. The cost methodology summarized in Appendix C3 of the 2006 NO_X BACT Analysis Study report provides more details for the levelized annual O&M cost calculations and cost factors for the previously-analyzed feasible NO_X control alternatives[29].

TABLE 4-6SA – Estimated O&M Costs for NO_X Control Alternatives - MRY Station Unit 1 - Stand Alone SCR Projects

Alt. Label(1)	**NOx Control Alternative**	**Annual O&M Cost(2) $1,000**	**Levelized Annual O&M Cost(2),(3) $1,000**
T2	Hypothetical Tail End SCR w/ ASOFA – Scenario A(4)	20,048	25,034
T1	Hypothetical Tail End SCR w/ ASOFA – Scenario B(4)	29,361	36,664
L2	Hypothetical Low-Dust SCR w/ ASOFA – Scenario A(4)	16,908	21,114
L1	Hypothetical Low-Dust SCR w/ ASOFA – Scenario B(4)	27,882	34,817
E	SNCR w/ ASOFA	5,417	6,764
D	Gas Reburn w/ ASOFA	28,641	35,765
C	Lignite Reburn w/ ASOFA(5)	5,862	7,320
B	FLGR w/ ASOFA	12,863	16,062
A	Advanced SOFA (ASOFA)	1,695	2,117
	Baseline	0	0

(1) - Alternative label has been assigned from highest to lowest unit NOx emission rate.
(2) - Annual operating and maintenance cost for a particular technology or combination is compared to unit baseline operation at an average unit output (244.5 MWg) and assumes a 97.3% average annual availability, which is highest consecutive 12-months of operation from 2001-2005. All cost figures in 2006 dollars.
(3) - Levelized annual O&M cost = Annual O&M cost x 1.24873 annualized O&M cost factor.
(4) - The inclusion of tail-end and low-dust SCR technologies in this table does not constitute agreement that it is technically feasible to install these technologies on Unit 1 at Milton R. Young Station. The estimated annual O&M cost shown for a hypothetically-applied SCR system is based on assumptions that known or expected reasons for technical infeasibility for installation and operation and maintenance of the SCR equipment on this boiler are solvable. Costs are derived from Burns & McDonnell internal database and cost estimates specific to MRYS Unit 1 in 2018 dollars. SCR technology is considered technically infeasible by Minnkota for application at MRYS per the October 2006 NO_X BACT Analysis Study report and subsequent submittals in response to comments by the NDDH, EPA, DOJ, and other parties, so this information for the hypothetical application of SCR alternatives is included for comparative purposes only. See Section 4.2.1.2.1 for details of Scenario A and Scenario B that assume replacement of SCR catalyst after a specified number of hours of unit operation.
(5) - Costs for increased PM collection capacity included in lignite reburn option are $2,024,000/yr for annual O&M cost, and $2,527,000/yr annualized O&M cost.

	Baseline	0	0

(1) - Alternative label has been assigned from highest to lowest unit NOx emission rate.

(2) - Annual operating and maintenance cost for a particular technology or combination is compared to unit baseline operation at an average unit output (244.5 MWg) and assumes a 97.3% average annual availability, which is highest consecutive 12-months of operation from 2001-2005. All cost figures in 2006 dollars.

(3) - Levelized annual O&M cost = Annual O&M cost x 1.24873 annualized O&M cost factor.

(4) - The inclusion of tail-end and low-dust SCR technologies in this table does not constitute agreement that it is technically feasible to install these technologies on Unit 1 at Milton R. Young Station. The estimated annual O&M cost shown for a hypothetically-applied SCR system is based on assumptions that known or expected reasons for technical infeasibility for installation and operation and maintenance of the SCR equipment on this boiler are solvable. Costs are derived from Burns & McDonnell internal database and cost estimates specific to MRYS Unit 1 in 2018 dollars. SCR technology is considered technically infeasible by Minnkota for application at MRYS per the October 2006 NO_X BACT Analysis Study report and subsequent submittals in response to comments by the NDDH, EPA, DOJ, and other parties, so this information for the hypothetical application of SCR alternatives is included for comparative purposes only. See Section 4.2.1.2.1 for details of Scenario A and Scenario B that assume replacement of SCR catalyst after a specified number of hours of unit operation.

(5) - Costs for increased PM collection capacity included in lignite reburn option are $2,024,000/yr for annual O&M cost, and $2,527,000/yr annualized O&M cost.

4.2.1.2.1 O&M COST ESTIMATES FOR HYPOTHETICAL APPLICATION OF SCR NO_X CONTROL ALTERNATIVES

The hypothetical application of tail-end and low-dust SCR w/ ASOFA alternatives will involve significantly higher operating costs compared with the existing operation of MRYS Unit 1. The system uses an amine reagent in the form of concentrated aqueous urea solution, which is thermally converted to gaseous ammonia, carbon dioxide, and water vapor. The estimated unit cost of this urea was assumed to average $379/ton (delivered to the plant site via truck-tanker trailers; unit pricing based on 50% concentration as established for the 2006 NO_X BACT Analysis Study report). Consumption of urea converted to ammonia reagent was based upon recent equipment vendor budgetary proposals and SCR consultant inputs.

For the hypothetically-applied SCR cases, using the existing induced draft fans is not expected to significantly change the overall fan horsepower demand on those fans' electric motors. There will be new plant electrical power demand due to a new induced draft booster fan required to overcome the estimated additional flue gas pressure drop resulting from reactor, ductwork, and gas-to-gas heat exchanger equipment assumed for the hypothetically-applied SCR systems. The additional auxiliary electric power demand for the hypothetically-applied tail end SCR systems was calculated to be 9.7 MW, using estimated annual average electrical loads of the booster fan, direct flue gas reheat burner combustion air fan, urea-to-ammonia conversion dilution/combustion air fan, and SCR sootblower and service air compressor equipment based on preliminary equipment vendor budgetary proposals developed from Burns & McDonnell ductwork sizing and designs. Estimated annual average electrical power demands for hypothetically-applied low-dust SCR systems were calculated to be 8.0 MW. Replacement of electrical power resulting from these reductions in net unit electrical output was included as a cost, assuming $35 per megawatt-hour.

Hypothetically-applied tail end and low-dust SCR equipment requiring annual maintenance includes booster fan, gas-to-gas heat exchangers, flue gas reheat duct burners, and compressor equipment. This general annual maintenance cost was estimated as 3 percent of installed capital costs.

To account for the possible range of O & M costs due to catalyst replacement, two variations (Scenario A and Scenario B) were applied. These two scenarios were used for both hypothetical applications of tail-end and low-dust SCR technology alternatives. Each scenario was based on scheduled additions and/or replacement of the exposed catalyst after a certain number of hours of operation, repeated throughout the 20 year operating span considered in the analysis. The installed unit cost of replacement catalyst assumed for the hypothetical application of full-time tail end or low-dust SCR alternatives is $7,500 per cubic meter in 2006 dollars. The basis for development of the two scenarios is described below.

During preparation of the cost estimate, Burns & McDonnell consulted with two SCR catalyst vendors experienced with biomass-fired boiler SCRs and European coal-fired boilers with low-dust and tail end SCR systems. However, neither of these vendors was willing to guarantee a catalyst replacement schedule for cyclone boilers firing North Dakota lignite without results following successful extensive pilot-scale slipstream testing that confirm the deactivation and fouling rates. According to these catalyst suppliers, there is no SCR operating experience in the world found to be directly comparable to the hypothetically-applied tail end and low-dust SCR cases on North Dakota lignite-fired cyclone boilers being evaluated. Thus they were unable to offer a guaranteed catalyst replacement schedule based on their experience.

Based on information obtained in discussions with the catalyst vendors, the longest catalyst replacement schedule they would both agree upon as an estimated (not guaranteed) value was 16,000 hours. Both vendors indicated that actual experience could result in a shorter replacement cycle, and that the actual guarantee value could not be developed until extensive pilot slipstream testing had been completed. This led Burns & McDonnell to develop two hypothetically-applied SCR catalyst replacement scenarios to bracket possible outcomes.

Scenario A assumed a hypothetically-applied catalyst replacement schedule of 16,000 hours. Specifically for MRYS Unit 1, this scenario is based on the replacement of one catalyst layer every 16,000 operating hours (essentially every two years of operation).

Scenario B assumed that the fouling of the catalyst would be severe, and that it would be necessary for Minnkota to perform catalyst maintenance at each scheduled boiler cleaning outage. The current schedule of boiler cleaning outages on Unit 1 is three times per year. Therefore, Scenario B for Unit 1 is based on the replacement of one catalyst layer at each boiler cleaning outage. This means that each catalyst layer in the four layer SCR reactor is exposed to flue gas during approximately 16 months of operation and then is replaced. By assuming that catalyst management activities would coincide with scheduled boiler cleaning outages, Scenario B provides some minimization of the impact of catalyst replacement on unit operation.

As noted above, it is not known what the actual frequency of catalyst replacement would need to be for a hypothetically-applied tail-end or low dust SCR system operating on a cyclone-fired boiler burning North Dakota lignite, but the two scenarios described above are the catalyst replacement numbers assumed for this comparative economic analysis.

SCR catalyst replacements are additive to the general annual hypothetically-applied low-dust and tail end SCR equipment maintenance. Catalyst replacement costs are based on catalyst vendor quotation of volume of catalyst, estimated to be three layers initially (top, middle-upper and middle-lower) at 146 cubic meters per layer per reactor for the single reactor. A fourth (bottom) layer at 195 cubic meters is expected to be required after initial operation of hypothetically-applied full-time tail end or low-dust SCR alternatives, as part of the catalyst replacement program. Catalyst replacement costs for the hypothetical application of SCR alternatives were estimated for the two different catalyst management scenarios described above.

Annual unit operating time will be reduced as a result of the expected outages and maintenance of the hypothetically-applied SCR equipment, including catalyst cleaning and management practices. Additional outage time of 213 hours per year was estimated to be attributable to the hypothetical application of tail end SCR Scenario A alternative (assuming 16,000 hour catalyst life), and 938 hours per year for Scenario B TESCR case (assuming three layers are replaced every year) over and above the hours per year of outage time assumed for ASOFA impacts. Additional outage time of 256 hours per year was estimated to be attributable to the hypothetical application of low-dust SCR Scenario A alternative, and 981 hours per year for the Scenario B LDSCR case over and above outage time assumed for ASOFA impacts. The expected loss of electrical power generation from these reductions in net output was included as a cost, assuming $35 per megawatt-hour for replacement power.

Table C.4-1 provides the estimated unit availability and corresponding operating time and outage time due to the four hypothetically-applied SCR technology cases, along with the ASOFA and baseline numbers from the referenced Appendix C3 of the initial NO_X BACT Analysis Study report[30].

TABLE C.4-1 – Expected Availability Reductions for MRYS Unit 1 NO_X Controls

Alt.[1]	NOx Control Alternative	Estimated Annual Average Unit Operating Time			
		Unit Availability[2]	Unit Operating Time[3], hrs/yr	Unit Outage Time[4], hrs/yr	Unit Operating Time Reduction[5], hrs/yr
T2	Hypothetical Tail End SCR w/ ASOFA – Scenario A(6)	0.928	8127	633	401
T1	Hypothetical Tail End SCR w/ ASOFA – Scenario B(6)	0.845	7402	1358	1126
L2	Hypothetical Low-Dust SCR w/ ASOFA – Scenario A(6)	0.923	8084	676	444
L1	Hypothetical Low-Dust SCR w/ ASOFA – Scenario B(6)	0.840	7359	1401	1169
E	SNCR w/ ASOFA	0.942	8255	505	273
D	Gas Reburn w/ ASOFA	0.952	8340	420	188
C	Coal Reburn w/ ASOFA	0.937	8212	548	316
B	FLGR w/ ASOFA	0.952	8340	420	188
A	Advanced SOFA (ASOFA)	0.952	8340	420	188
	Baseline	0.973	8528	232	0

(1) – Alternative number has been previously assigned from least removal to highest removal percentage.
(2) – 12-month baseline availability is assumed at 97.3 percent. These values reflect estimated amounts of negative reliability impact expected from the implementation of the individual NOx control technology.
(3) – Annual operating time is annual average availability multiplied by 8760 hrs/yr of possible uptime.
(4) – Annual outage time is 8760 hrs/yr possible operating time minus estimated annual operating time.
(5) – Annual operating time reduction resulting from the implementation of the individual NOx control technique is the difference between the baseline and expected annual outage times.
(6) – The inclusion of tail-end and low-dust SCR technologies in this table does not constitute agreement that it is technically feasible to install these technologies on Unit 1 at Milton R. Young Station. The estimated annual unit availability factors shown for hypothetically-applied SCR systems are based on assumptions that known or expected reasons for technical infeasibility for installation and operation and maintenance of the SCR equipment on this boiler are solvable. SCR technology is considered technically infeasible by Minnkota for application at MRYS per the October 2006 NO_X BACT Analysis Study report and subsequent submittals in response to comments by the NDDH, EPA, DOJ, and other parties, so this information for the hypothetical application of SCR alternatives is included for comparative purposes only. See Section 4.2.1.2.1 for details of Scenario A and Scenario B that assumes replacement of SCR catalyst after a specified number of hours of unit operation.

Table C.4-2 includes estimated equivalent average annual unit running plant capacity ratios and unit generation reductions due to the four hypothetically-applied SCR cases, along with the ASOFA and baseline numbers from the referenced Appendix C3 of the initial NO_X BACT Analysis Study report[31]. These numbers assume the reduction in annual plant output is a combination of a reduction of annual operating time and capacity reductions associated with the control alternatives.

TABLE C.4-2 – Expected Capacity Reductions for MRYS Unit 1 NO_X Controls

Alt. Label[(1)]	NOx Control Alternative	Estimated Annual Average Unit Electrical Power Generation Reduction from Operating Time Reduction: Unit Running Plant Capacity Ratio[(2)]	Unit Generation Reduction[(3)] kW-hrs/yr	Unit Generation Reduction Cost[(4)], 1000$/yr
T2	Hypothetical Tail End SCR w/ ASOFA – Scenario A[(5)]	0.937	97,976,764	3,429
T1	Hypothetical Tail End SCR w/ ASOFA – Scenario B[(5)]	0.937	275,168,784	9,631
L2	Hypothetical Low-Dust SCR w/ ASOFA – Scenario A[(5)]	0.942	108,399,824	3,794
L1	Hypothetical Low-Dust SCR w/ ASOFA – Scenario A[(5)]	0.942	285,591,844	11,940
E	SNCR w/ ASOFA	0.965	67,660,606	2,368
D	Gas Reburn w/ ASOFA	0.957	46,120,681	1,614
C	Lignite Reburn w/ ASOFA	0.961	77,958,350	2,729
B	FLGR w/ ASOFA	0.962	46,400,200	1,624
A	Advanced SOFA (ASOFA)	0.966	46,586,546	1,631
	Baseline	0.966	0	0

(1) - Alternative designation has been previously assigned from least removal to highest removal percentage.
(2) - 12-month baseline running plant capacity ratio is assumed at 96.6 percent (= 244.4/253.0). These values reflect estimated amounts of negative annual output capacity impact expected from the implementation of the individual NOx control technique. Used only for calculation of annual power usage in Table C.4-3.
(3) - Annual electricity generation reduction is annual unit operating time reduction multiplied by the 12-month average gross output of 244.4 MW.
(4) - Annual electricity generation reduction cost is the annual electricity generation reduction (kW-hrs/yr) resulting from the implementation of the individual NOx control technique multiplied by the incremental value of electricity generation, assumed to be $35.00/MW-hr. All cost figures in 2006 dollars.
(5) - The inclusion of tail-end and low-dust SCR technologies in this table does not constitute agreement that it is technically feasible to install these technologies on Unit 1 at Milton R. Young Station. The estimated annual unit running plant capacity factors shown for hypothetically-applied SCR systems are based on assumptions that known or expected reasons for technical infeasibility for installation and operation and maintenance of the SCR equipment on this boiler are solvable. SCR technology is considered technically infeasible by Minnkota for application at MRYS per the October 2006 NO_X BACT Analysis Study report and subsequent submittals in response to comments by the NDDH, EPA, DOJ, and other parties, so this information for the hypothetical application of SCR alternatives is included for comparative purposes only. See Section 4.2.1.2.1 for details of Scenario A and Scenario B that assumes replacement of SCR catalyst after a specified number of hours of unit operation.

Table C.4-3 includes estimated unit gross and net electrical power demands (kilowatts) and annual usage (kW-hrs per year) used to calculate unit generation reductions and replacement electrical power costs due to the four hypothetically-applied SCR cases, along with the ASOFA numbers from the referenced Appendix C3 of the initial NO_X BACT Analysis Study report[32]. These numbers assume that the reductions of annual operating time and capacity associated with the control alternatives are also applied.

TABLE C.4-3 – Expected Auxiliary Electrical Power Demand Changes for MRYS Unit 1 NO_X Controls

Alt. Label(1)	NOx Control Alternative	Estimated Annual Average APC NOx Equipment Auxiliary Electrical Power Demand and Usage				
		Gross Demand (2) kW	Credit(3) kW	Total Net Demand(4) kW	Power Usage(5) kW-hrs/yr	Power Usage Cost(6), 1000$/yr
T2	Hypothetical Tail End SCR w/ ASOFA – Scenario A(7)	9,685	0	9,685	73,768,605	2,582
T1	Hypothetical Tail End SCR w/ ASOFA – Scenario B(7)	9,685	0	9,685	67,189,753	2,352
L2	Hypothetical Low-Dust SCR w/ ASOFA – Scenario A(7)	8,012	0	8,012	61,018,532	2,136
L1	Hypothetical Low-Dust SCR w/ ASOFA – Scenario A(7)	8,012	0	8,012	55,548,184	1,944
E	SNCR w/ ASOFA	73.1	0	73.1	582,411	20
D	Gas Reburn w/ ASOFA	1	133	(132)	(1,054,343)	(37)
C	Lignite Reburn w/ ASOFA	4,666	261	4,405	11,905,082	1,217
B	FLGR w/ ASOFA	1	73	(72)	(578,744)	(20)
A	Advanced SOFA (ASOFA)	1	0	1	8,058	0.3

(1) - Alternative designation has been previously assigned from least removal to highest removal percentage.
(2) - The APC NOx equipment gross auxiliary electrical power demand of alternatives is the sum of the demand for individual technologies combined by simple addition. Actual power demands may differ from this due to positive or negative synergistic effects. Coal reburn includes 1,507 kW for feed preparation and conveying equipment demand plus 3,158 kW for the COHPAC system addition for PM control.
(3) - The APC NOx equipment auxiliary electrical power demand credit of coal reburn alternatives is the estimated result of lower cyclone coal preparation and feeder power demand due to lower boiler cyclone coal equipment loading. Actual power demands may differ from this due to accuracy of estimates for assumed amount of operating horsepower reduction.
(4) - The total net auxiliary electrical power demand is the sum of the gross demand and credit.
(5) - The annual change in APC NOx equipment auxiliary electrical power demand electricity usage in kW-hrs/yr for these alternatives is the net power demand multiplied by the estimated annual operating time and running plant capacity ratio which reflects the adjustment for any expected availability and capacity impacts from the implementation of the control technique.
(6) - The annual change in APC NOx equipment auxiliary electrical power demand electricity cost is the annual change in kW-hrs/yr for these alternatives resulting from the implementation of the individual NOx control technique multiplied by the incremental value of electricity generation, assumed to be $35.00/MW-hr. All cost figures in 2006 dollars.
(7) - The inclusion of tail-end and low-dust SCR technologies in this table does not constitute agreement that it is technically feasible to install these technologies on Unit 1 at Milton R. Young Station. The estimated power demands shown for hypothetically-applied SCR systems are based on Burns & McDonnell estimates developed from preliminary equipment and ductwork sizing and designs with vendor budgetary proposals. SCR technology is considered technically infeasible by Minnkota for application at MRYS per the October 2006 NO_X BACT Analysis Study report and subsequent submittals in response to comments by the NDDH, EPA, DOJ, and other parties, so this information for the hypothetical application of SCR alternatives is included for comparative purposes only. See Section 4.2.1.2.1 for details of Scenario A and Scenario B that assumes replacement of SCR catalyst after a specified number of hours of unit operation.

Table C.4-4 includes estimated net unit electrical annual power usage (kW-hrs per year) and expected reductions in annual operating time to calculate unit generation reductions due to the four hypothetically-applied SCR cases, along with the ASOFA numbers from the referenced Appendix C3 of the initial NO_X

BACT Analysis Study report[33]. These numbers assume the reduction in annual plant output is a combination of a reduction of net unit generation because of electrical power usage and reductions in annual operating time and capacity associated with the control alternatives.

TABLE C.4-4 – Expected Auxiliary Electrical Power Demand and Generation Reduction Cost Changes for MRY Unit 1 NO_X Controls

Alt. Label[(1)]	**NOx Control Alternative**	**Estimated Annual Change in Unit Generation Due to APC NOx Equipment Auxiliary Power Electricity Demand and Generation Reduction**			
		APC Electrical Power Usage[(2)] kW-hrs/yr	**Unit Generation Reduction[(3)] kW-hrs/yr**	**Total Unit Electrical Power Generation Change[(4)] kW-hrs/yr**	**Total Unit Electrical Power Generation Change Cost[(5)] 1000$/yr**
T2	Hypothetical Tail End SCR w/ ASOFA – Scenario A[(6)]	73,768,605	97,976,764	171,745,369	6,011
T1	Hypothetical Tail End SCR w/ ASOFA –Scenario B[(6)]	67,189,753	275,168,784	342,358,537	11,983
L2	Hypothetical Low-Dust SCR w/ ASOFA – Scenario A[(6)]	61,018,532	108,399,824	169,418,356	5,930
L1	Hypothetical Low-Dust SCR w/ ASOFA – Scenario B[(6)]	55,548,184	285,591,844	341,140,028	11,940
E	SNCR w/ ASOFA	582,411	67,660,606	68,243,017	2,389
D	Gas Reburn w/ ASOFA	(1,054,343)	46,120,681	45,066,338	1,577
C	Lignite Reburn w/ ASOFA	11,905,082	77,958,350	89,863,432	3,946
B	FLGR w/ ASOFA	(578,744)	46,400,200	45,821,456	1,604
A	Advanced SOFA (ASOFA)	8,058	46,586,546	46,594,605	1,631

(1) - Alternative designation has been previously assigned from least removal to highest removal percentage.
(2) - The annual change in APC NOx equipment auxiliary electrical power demand electricity usage in kW-hrs/yr for these alternatives is the net power demand multiplied by the estimated annual operating time and running plant capacity ratio which reflects the adjustment for any expected availability and capacity impacts from the implementation of the control technique.
(3) - Annual electricity generation reduction is annual operating time reduction multiplied by the 12-month average gross output of 244.4 MW.
(4) - The total unit electrical power generation change is the sum of the annual change in APC NOx equipment auxiliary electrical power demand electricity usage plus the annual electricity generation reduction resulting from the implementation of the individual NOx control alternative.
(5) - The total unit electrical power generation change cost is the total generation change (kw-hrs/yr) multiplied by the incremental value of electricity generation, assumed to be $35.00/MW-hr. All cost figures in 2006 dollars.
(6) - The inclusion of tail-end and low-dust SCR technologies in this table does not constitute agreement that it is technically feasible to install these technologies on Unit 1 at Milton R. Young Station. The estimated power demand shown for hypothetically-applied SCR systems are based on Burns & McDonnell estimates developed from preliminary equipment and ductwork sizing and designs with vendor budgetary proposals. SCR technology is considered technically infeasible by Minnkota for application at MRYS per the October 2006 NO_X BACT Analysis Study report and subsequent submittals in response to comments by the NDDH, EPA, DOJ, and other parties, so this information for the hypothetical application of SCR alternatives is included for comparative purposes only. See Section 4.2.1.2.1 for details of Scenario A and Scenario B that assumes replacement of SCR catalyst after a specified number of hours of unit operation.

4.2.1.3 LEVELIZED TOTAL ANNUAL COST ESTIMATES FOR MRY STATION NO_X CONTROLS

A comparison of the control versus cost-effectiveness of four hypothetically-applied SCR cases and previously-analyzed feasible NO_X control alternatives on Milton R. Young Unit 1 was made. This is summarized as shown in Tables 4-7SA and 4-7SF, Figures 4-1SA and 4-1SF, and Figures 4-2SA and 4-2SF for MRY Station Unit 1.

TABLE 4-7SA – Estimated Annual Emissions and Levelized Total Annual Cost for NO_X Control Alternatives - MRY Station Unit 1 - Stand Alone SCR Projects

Alt. Label(1)	NOx Control Alternative	Annual NOx Emissions(2) Tons/yr	Annual NOx Emissions Reduction(3) Tons/yr	Levelized Total Annual Cost(4) $1,000	Average Control Cost(5) $/ton
T2	Hypothetical Tail End SCR w/ ASOFA – Scenario A(6)	589	9,345	44,465	4,758
T1	Hypothetical Tail End SCR w/ ASOFA – Scenario B(6)	536	9,398	56,095	5,969
L2	Hypothetical Low-Dust SCR w/ ASOFA – Scenario A(6)	586	9,348	36,872	3,944
L1	Hypothetical Low-Dust SCR w/ ASOFA – Scenario B(6)	533	9,401	50,575	5,380
E	SNCR w/ ASOFA	4,025	5,909	7,472	1,265
D	Gas Reburn w/ ASOFA	4,275	5,659	37,334(7)	6,597
C	Lignite Reburn w/ ASOFA	4,343	5,591	11,388(8)	2,037
B	FLGR w/ ASOFA	5,260	4,674	16,990(7)	3,635
A	Advanced SOFA (ASOFA)	5,874	4,060	2,489	613
	Baseline	9,934	0	0	

(1) - Alternative label has been assigned from highest to lowest unit NOx emission rate.

(2) - Estimated annual emission tons assume an annual unit uptime availability factor specific to each alternative; 9,934 (= 0.973*8760*2,330/2000) was assumed for the baseline case.

(3) - Estimated annual tons of emission reduction is the difference between annual baseline tons and each alternative's annual emissions (tons).

(4) - Levelized Total Annual Cost = Annualized Installed Capital Cost + Levelized Annual O&M cost. See note 3 from Tables 4-4SA and 4-6SA for annualized cost factors. Emissions are calculated from unit emission rates, control percentage, hourly heat input, and annual hrs/yr operation compared to pre-control baseline emissions based on annual operation at baseline pre-control NOx emission rate.

(5) - Average Control Cost Effectiveness ($/ton) is the Levelized Total Annual Cost ($/yr) divided by Annual Emission Reduction (tons/yr). All cost figures in 2006 dollars.

(6) - The inclusion of tail-end and low-dust SCR technologies in this table does not constitute agreement that it is technically feasible to install these technologies on Unit 1 at Milton R. Young Station. The estimated annual NOx removal and LTAC shown for a hypothetically-applied SCR system is based on assumptions that known or expected reasons for technical infeasibility for installation of the SCR equipment on this boiler are solvable. Costs are derived from Burns & McDonnell internal database and cost estimates specifically for MRYS Unit 1 in 2006 dollars. SCR technology is considered technically infeasible by Minnkota for application at MRYS per the October 2006 NO_X BACT Analysis Study report and subsequent submittals in response to comments by the NDDH, EPA, DOJ, and other parties, so this

information for the hypothetical application of SCR alternatives is included for comparative purposes only. See Section 4.2.1.2.1 for details of Scenario A and Scenario B that assumes replacement of SCR catalyst after a specified number of hours of unit operation.

(7) - LTAC for gas reburn options include high-pressure natural gas supply pipeline annualized capital cost of $704,000/yr for CGR and $352,000 for FLGR. See footnote number 8 under Table 4-3SA.

(8) - LTAC for increased PM collection capacity included in lignite reburn option are approximately $2,054,000 for annualized capital cost plus $2,527,000/yr for annualized O&M cost, for a LTAC subtotal of $4,581,000/yr.

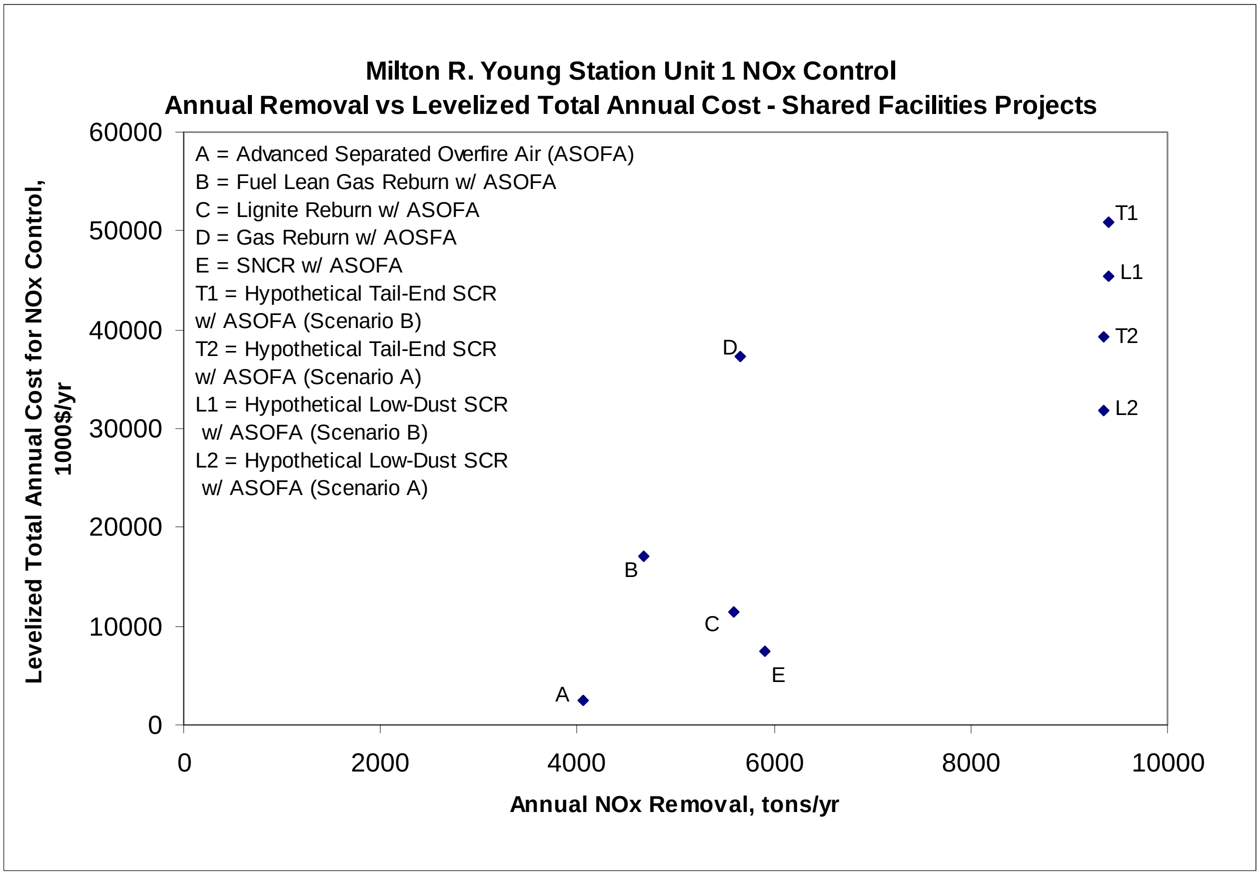
(2) - The inclusion of tail-end and low-dust SCR technologies in this figure does not constitute agreement that it is technically feasible to install these technologies on Unit 1 at Milton R. Young Station. The estimated annual NOx removal and LTAC shown for a hypothetically-applied SCR system is based on assumptions that known or expected reasons for technical infeasibility for installation of the SCR equipment on this boiler are solvable. SCR technology is considered technically infeasible by Minnkota for application at MRYS per the October 2006 NO$_X$ BACT Analysis Study report and subsequent submittals in response to comments by the NDDH, EPA, DOJ, and other parties, so this information for the hypothetical application of SCR alternatives is included for comparative purposes only. See Section 4.2.1.2.1 for details of Scenario A and Scenario B that assumes replacement of SCR catalyst after a specified number of hours of unit operation.

Figure 4-1SF – NO_X Control Cost Effectiveness - MRY Station Unit 1(1)
Shared Facilities SCR Projects



(1) - All cost figures in 2006 dollars. Numbers are listed and qualifiers are noted in Table 4-7SF.

(2) - The inclusion of tail-end and low-dust SCR technologies in this figure does not constitute agreement that it is technically feasible to install these technologies on Unit 1 at Milton R. Young Station. The estimated annual NOx removal and LTAC shown for a hypothetically-applied SCR system is based on assumptions that known or expected reasons for technical infeasibility for installation of the SCR equipment on this boiler are solvable. SCR technology is considered technically infeasible by Minnkota for application at MRYS per the October 2006 NO_X BACT Analysis Study report and subsequent submittals in response to comments by the NDDH, EPA, DOJ, and other parties, so this information for the hypothetical application of SCR alternatives is included for comparative purposes only. See Section 4.2.1.2.1 for details of Scenario A and Scenario B that assumes replacement of SCR catalyst after a specified number of hours of unit operation.

The purpose of Figures 4-1SA and 4-1SF is to show the range of control and cost for four hypothetically-applied SCR cases and previously-analyzed feasible NO_X control alternatives on Milton R. Young Unit 1 alternatives evaluated.

Data points for conventional gas reburn (Point D) and fuel-lean gas reburn (Point B) with advanced separated overfire air, and lignite reburn with ASOFA (Point C), in Figures 4-1SA and 4-1SF are inferior and therefore were eliminated from further control cost-effectiveness analysis.

A dominant set of control alternatives was determined by generating what is called the “envelope of least-cost alternatives”. The dominant controls cost curve is the best fit line through the points forming the rightmost boundary of the data zone on a scatter plot of the annual NO_X removal tonnage versus LTAC for the various remaining BACT alternatives. Average and incremental annual costs and NO_X emission reductions for the dominant least-cost control alternatives remaining after the elimination of the obviously inferior options are listed in Tables 4-8SA and 4-8SF.

TABLE 4-8SA – Dominant Controls Cost Curve Points for NO_X Control Alternatives - MRY Station Unit 1 - Stand Alone SCR Projects

Alt. Label(1)	NOx Control Alternative	Levelized Total Annual Cost(2),(3) ($1,000/yr)	Annual Emission Reduction(3) (tpy)	Incremental Levelized Total Annual Cost(2),(4) ($1,000/yr)	Incremental Annual Emission Reduction(4) (tpy)	Incremental Control Cost Effectiveness ($/ton)(2),(4)
T2	Hypothetical Tail End SCR w/ ASOFA – Scenario A(5)	44,465	9,345	36,993	3,437	10,765
T1	Hypothetical Tail End SCR w/ ASOFA – Scenario B(5)	56,095	9,398	48,623	3,489	13,936
L2	Hypothetical Low-Dust SCR w/ ASOFA – Scenario A(5)	36,872	9,348	29,400	3,440	8,547
L1	Hypothetical Low-Dust SCR w/ ASOFA – Scenario B(5)	50,575	9,401	43,103	3,492	12,343
E	SNCR w/ ASOFA	7,472	5,909	4,982	1,849	2,694
A	Advanced SOFA (ASOFA)	2,489	4,060	2,489	4,060	613

(1) - Alternative label has been assigned from highest to lowest unit NOx emission rate. Dominant controls cost curve points from lowest (ASOFA) to highest (TESCR w/ ASOFA – 16,000 hrs) are labeled the same as in Table 4-7SA, and on the graphs that accompany this table (Points B, C, and D were eliminated).

(2) - All cost figures in 2006 dollars.

(3) - Annual emission reduction and levelized control cost of these alternatives is relative to current costs and pre-control unit MCR baseline emission rate.

(4) - Increment based upon comparison between consecutive alternatives (points) from lowest to highest.

(5) - The inclusion of tail-end and low-dust SCR technologies in this table does not constitute agreement that it is technically feasible to install these technologies on Unit 1 at Milton R. Young Station. The annual NOx removal and LTAC shown for a hypothetically-applied SCR system is based on assumptions that known or expected reasons for technical infeasibility for installation of the SCR equipment on this boiler are solvable. SCR technology is considered technically infeasible by Minnkota for application at MRYS per the October 2006 NO_X BACT Analysis Study report and subsequent submittals in response to comments by the NDDH, EPA, DOJ, and other parties, so this information for the hypothetical application of SCR alternatives is included for comparative purposes only. See Section 4.2.1.2.1 for details of Scenario A and Scenario B that assumes replacement of SCR catalyst after a specified number of hours of unit operation.

TABLE 4-8SF – Dominant Controls Cost Curve Points for NO_X Control Alternatives - MRY Station Unit 1 - Shared Facilities SCR Projects

Alt. Label(1)	NOx Control Alternative	Levelized Total Annual Cost(2),(3) ($1,000/yr)	Annual Emission Reduction(3) (tpy)	Incremental Levelized Total Annual Cost(2),(4) ($1,000/yr)	Incremental Annual Emission Reduction(4) (tpy)	Incremental Control Cost Effectiveness ($/ton)(2),(4)
T2	Hypothetical Tail End SCR w/ ASOFA – Scenario A(5)	39,307	9,345	31,835	3,437	9,264

L1	Hypothetical Low-Dust SCR w/ ASOFA – Scenario B(5)	45,452	9,401	37,980	3,492	10,876
E	SNCR w/ ASOFA	7,472	5,909	4,982	1,849	2,694
A	Advanced SOFA (ASOFA)	2,489	4,060	2,489	4,060	613

(1) - Alternative label has been assigned from highest to lowest unit NOx emission rate. Dominant controls cost curve points from lowest (ASOFA) to highest (TESCR w/ ASOFA – 16,000 hrs) are labeled the same as in Table 4-7SF, and on the graphs that accompany this table (Points B, C, and D were eliminated).

(2) - All cost figures in 2006 dollars.

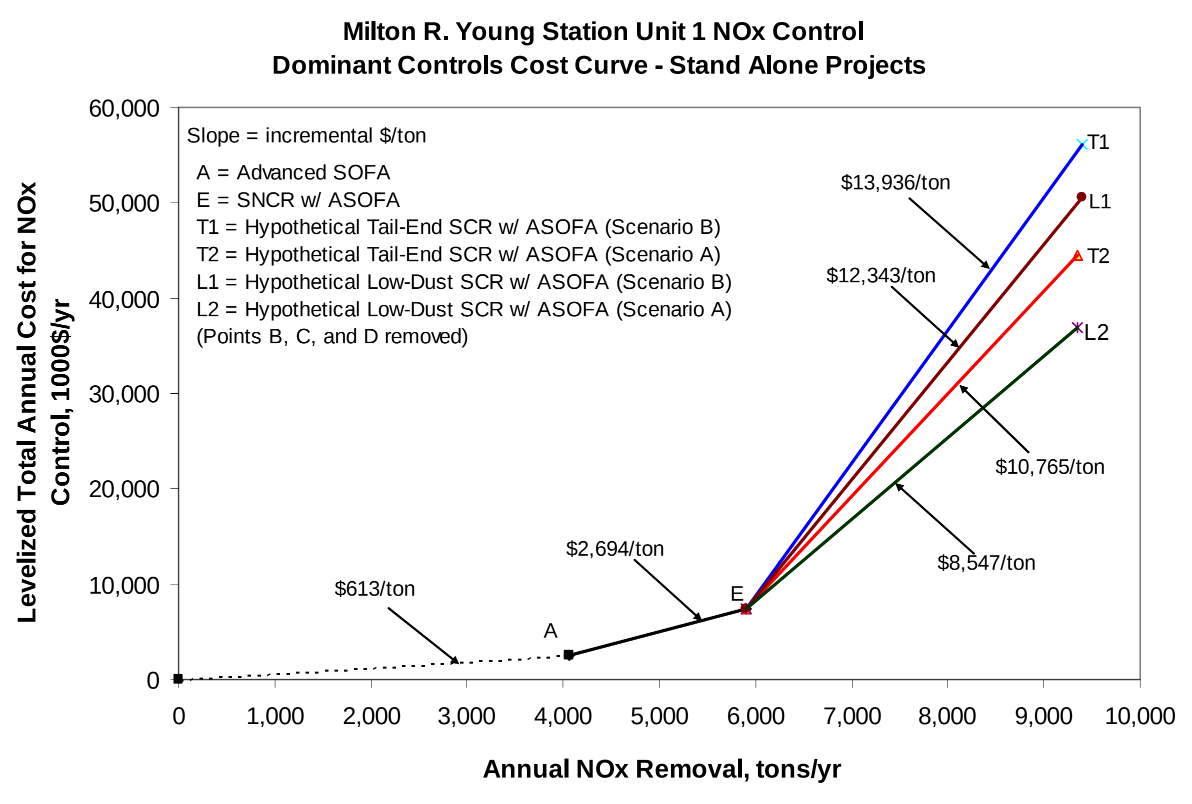
(3) - Annual emission reduction and levelized control cost of these alternatives is relative to current costs and pre-control unit MCR baseline emission rate.

(4) - Increment based upon comparison between consecutive alternatives (points) from lowest to highest.

(5) - The inclusion of tail-end and low-dust SCR technologies in this table does not constitute agreement that it is technically feasible to install these technologies on Unit 1 at Milton R. Young Station. The annual NOx removal and LTAC shown for a hypothetically-applied SCR system is based on assumptions that known or expected reasons for technical infeasibility for installation of the SCR equipment on this boiler are solvable. SCR technology is considered technically infeasible by Minnkota for application at MRYS per the October 2006 NO_X BACT Analysis Study report and subsequent submittals in response to comments by the NDDH, EPA, DOJ, and other parties, so this information for the hypothetical application of SCR alternatives is included for comparative purposes only. See Section 4.2.1.2.1 for details of Scenario A and Scenario B that assumes replacement of SCR catalyst after a specified number of hours of unit operation.

Figures 4-2SA and 4-2SF contains a repetition of the levelized total annual cost and NO_X control information from Figures 4-1SA and 4-1SF for MRY Station Unit 1, with Point B (FLGR™ with ASOFA) , Point C (Lignite Reburn with ASOFA) and Point D (conventional gas reburn with ASOFA) removed. This is the dominant controls cost curve for MRY Station Unit 1 NO_X emissions alternatives.

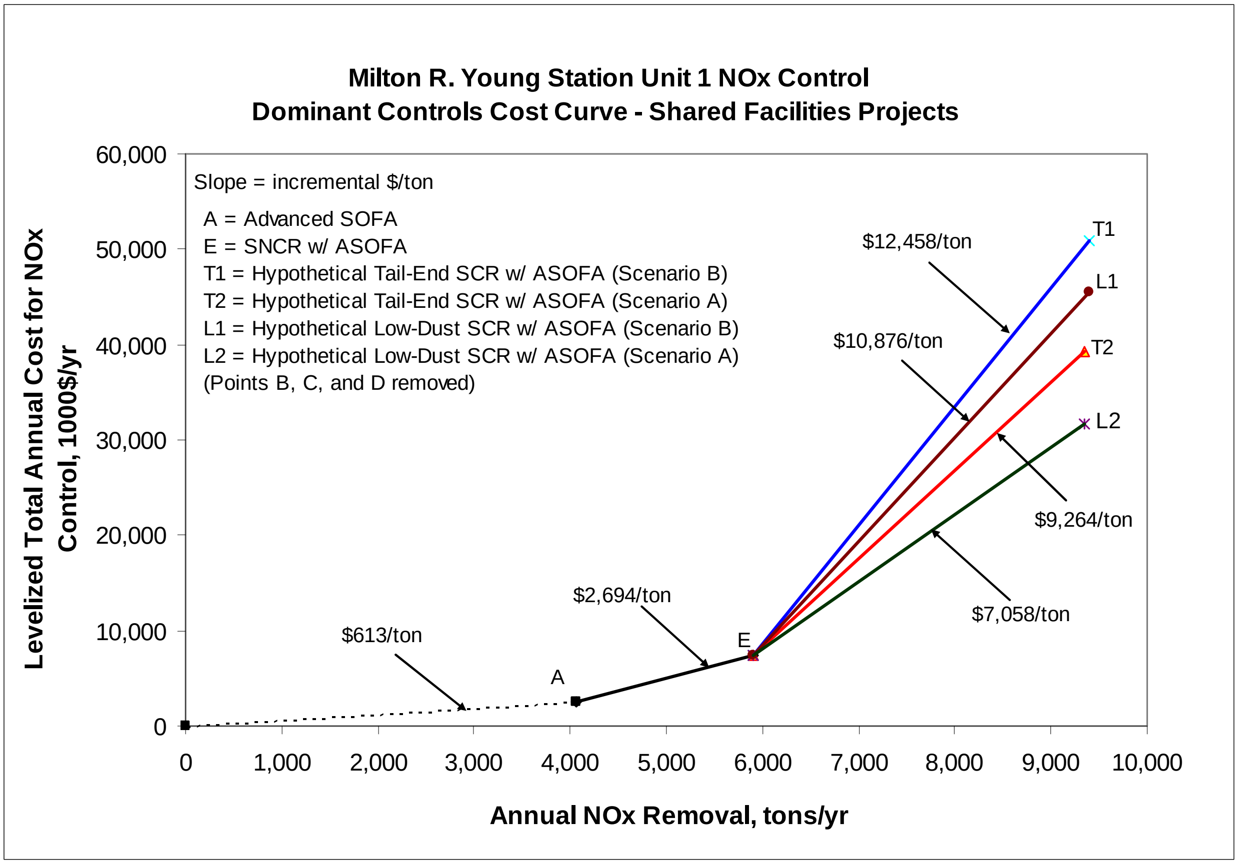
Figure 4-2SA – MRY Station Unit 1 NO_X Control Alternatives BACT Dominant Controls Cost Curve$^{(1)}$ - Stand Alone SCR Projects



(1) - All cost figures in 2006 dollars. Numbers are listed and qualifiers are noted in Table 4-8SA.

(2) - The inclusion of tail-end and low dust SCR technologies in this figure does not constitute agreement that it is technically feasible to install these technologies on Unit 1 at Milton R. Young Station. The estimated annual NOx removal and LTAC shown for a hypothetically-applied SCR system is based on assumptions that known or expected reasons for technical infeasibility for installation and operation and maintenance of the SCR equipment on this boiler are solvable. SCR technology is considered technically infeasible by Minnkota for application at MRYS per the October 2006 NO_X BACT Analysis Study report and subsequent submittals in response to comments by the NDDH, EPA, DOJ, and other parties, so this information for the hypothetical application of SCR alternatives is included for comparative purposes only. See Section 4.2.1.2.1 for details of Scenario A and Scenario B that assumes replacement of SCR catalyst after a specified number of hours of unit operation.

Figure 4-2SF – MRY Station Unit 1 NO_X Control Alternatives BACT Dominant Controls Cost Curve$^{(1)}$ – Shared Facilities SCR Projects



(1) - All cost figures in 2006 dollars. Numbers are listed and qualifiers are noted in Table 4-8SF.

(2) - The inclusion of tail-end and low dust SCR technologies in this figure does not constitute agreement that it is technically feasible to install these technologies on Unit 1 at Milton R. Young Station. The estimated annual NOx removal and LTAC shown for a hypothetically-applied SCR system is based on assumptions that known or expected reasons for technical infeasibility for installation and operation and maintenance of the SCR equipment on this boiler are solvable. SCR technology is considered technically infeasible by Minnkota for application at MRYS per the October 2006 NO_X BACT Analysis Study report and subsequent submittals in response to comments by the NDDH, EPA, DOJ, and other parties, so this information for the hypothetical application of SCR alternatives is included for comparative purposes only. See Section 4.2.1.2.1 for details of Scenario A and Scenario B that assumes replacement of SCR catalyst after a specified number of hours of unit operation.

As can be seen from a review of Tables 4-7SA and 4-7SF, the average levelized control cost effectiveness (called the unit control cost in this report) ranges from approximately $613/ton to $6,597/ton of MRYS Unit 1's NO_X emissions removed. The unit control cost for the hypothetically-applied Scenario A Tail End SCR w/ ASOFA case was $4,758/ton and for the hypothetically-applied Scenario B Tail End SCR w/ ASOFA case was $5,969/ton (stand alone projects). The unit control cost for the hypothetically-applied Scenario A Low-Dust SCR w/ ASOFA case was $3,944/ton and for the hypothetically-applied Scenario B Low-Dust SCR w/ ASOFA case was $5,380/ton (stand alone projects). The unit control cost for the hypothetically-applied Scenario A Tail End SCR w/ ASOFA case was $4,206/ton and for the hypothetically-applied

Scenario B Tail End SCR w/ ASOFA case was $5,420/ton (shared facilities projects). The unit control cost for the hypothetically-applied Scenario A Low-Dust SCR w/ ASOFA case was $3,396/ton and for the hypothetically-applied Scenario B Low-Dust SCR w/ ASOFA case was $4,835/ton (shared facilities projects). Unit control costs for SNCR w/ ASOFA was $1,265/ton, more than twice that of ASOFA ($613/ton). It should be noted, however, that the very high estimated average control costs involve fuel lean gas reburn ($3,635/ton) and conventional gas reburn ($6,597/ton) technologies that were shown to be inferior options (not on the dominant controls cost curve) and thus were eliminated from further impacts analysis.

The incremental cost analysis indicates that from a cost effectiveness viewpoint, the SNCR with ASOFA alternative for MRYS Unit 1 incurs a significant annual (levelized) incremental cost compared to the ASOFA NO_X control technique. The slope from zero (baseline) to ASOFA (Point A) was $613/ton; the incremental cost per ton (slope) from ASOFA (Point A) to SNCR with ASOFA (Point E) was $2,694/ton for MRYS Unit 1. The incremental cost per ton (slope) from SNCR with ASOFA (Point E) to the top hypothetically-applied low-dust SCR case (Point L2, Scenario A) was $8,547/ton (stand alone projects). The incremental cost per ton (slope) from SNCR with ASOFA (Point E) to the top hypothetically-applied tail end SCR case (Point T2, Scenario A) was $10,765/ton (stand alone projects). The incremental cost per ton (slope) from SNCR with ASOFA (Point E) to the second hypothetically-applied low-dust SCR case (Point L1, Scenario B) was $12,343/ton (stand alone projects). The incremental cost per ton (slope) from SNCR with ASOFA (Point E) to the second hypothetically-applied tail end SCR case (Point T1, Scenario B) was $13,936/ton (stand alone projects). For shared projects, the incremental cost per ton (slope) from SNCR with ASOFA (Point E) to the top hypothetically-applied SCR cases were $7,058/ton (low-dust Point L2, Scenario A) and $9,264/ton (tail end Point T2, Scenario A). For shared projects, the incremental cost per ton (slope) from SNCR with ASOFA (Point E) to the second hypothetically-applied SCR cases were $10,876/ton (low-dust, Point L1, Scenario B) and $12,458/ton (tail end Point T1, Scenario B).

In the U.S. EPA's NSR Manual, the EPA does not specify acceptable or unacceptable ranges for average (unit control costs) and incremental cost effectiveness values. EPA's NSR Manual however, does specifically address the standard to be used when rejecting a candidate technology on the basis of adverse economic impact:

> "Consequently, where unusual factors exist that result in cost/economic impacts beyond the range normally incurred by other sources in that category, the technology can be eliminated provided the applicant has adequately identified the circumstances,

> including the cost or other analyses, that show what is significantly different about the proposed source."[34]

This supplemental report for the MRYS NOx BACT Analysis has clearly established the circumstances, including the economic impacts, which would make the hypothetical application of TESCR or LDSCR to MRYS Unit 1 significantly more expensive than SCR costs normally incurred by other coal-fired steam electric generating units. The following information further supports EPA's own statements regarding the costs "normally incurred by other sources". The EPA's technical support document issued with the final Regional Haze Regulations and BART Guidelines estimated an average control cost for SCR applied to MRYS Unit 1 of $549 per ton[35]. The unadjusted unit capital cost versus capacity factor assumed by the EPA for SCR retrofits applied to cyclone boilers in the cost-effectiveness analysis used for establishing presumptive BART[36] was $100/kW. The EPA's cost-effectiveness analysis used for establishing presumptive BART stated that "applying SCR for coal-fired cyclone units is typically less than $1500 a ton, and that the average cost-effectiveness is $900 per ton" [37]. The site-specific control costs estimated for hypothetical application of tail-end and low-dust SCR alternatives to MRYS Unit 1 are significantly higher than the EPA's cost-effectiveness analysis for conventional SCR technologies included in the technical support document issued with the final Regional Haze Regulations and BART Guidelines discussed above.

Also, the use of incremental cost effectiveness is warranted per the final 2005 RHR/BART Guidelines, which state "the greater the number of possible control options that exist, the more weight should be given to the incremental costs vs. average costs". Also in the final 2005 RHR/BART Guidelines, "the average cost for each [of two options, A and B]… may be deemed to be reasonable. However, the incremental cost…of the additional emissions reductions to be achieved by control B may be very great. In such an instance, it may be inappropriate to chose control B, based on its higher incremental costs, even though its average cost may be considered reasonable".[38]

A	Advanced SOFA (ASOFA)	0.513	1,409	5,874	4,060	39.5	4,277	1,695	2,489	613
	Baseline	0.849	2,330	9,934	0	0.0	0	0	0	

(1) - Alternative label has been assigned from highest to lowest unit NOx emission rate.

(2) - Estimated NO$_X$ control level reductions relative to average annual unit emission baseline of 0.849 lb/mmBtu at 2,744 mmBtu/hr MCR heat input. Emissions are calculated from unit emission rates, control percentage, hourly heat input, and annual hrs/yr operation compared to pre-control baseline based on annual operation at a gross unit electrical output of 244.45 MWg and assumes a 97.3% average annual availability. Values from reported emission data for the 12 month operating period during 2001-2005 with the highest rolling summation of NOx pounds.

(3) - Installed capital cost is estimated for determination of total capital cost for a particular technology or combination, assuming 257 MWg unit capacity rating. All cost figures in 2006 dollars. Costs for gas reburn options include high-pressure natural gas supply pipeline installed capital cost of $8,075,000 for CGR and $4,038,000 for FLGR. Costs for increased PM collection capacity included in lignite reburn option are $23,561,000 for installed capital cost.

(4) - Annual operating and maintenance cost for a particular technology or combination is compared to unit baseline operation at a gross unit electrical output of 244.45 MWg and assumes a 96.6% average running plant capacity ratio compared to nominal unit gross electrical output capacity of 253 MWg. All cost figures in 2006 dollars. Costs for increased PM collection capacity included in lignite reburn option are $1,909,000/yr for annual O&M cost.

(5) - Levelized Total Annual Cost = Annualized Installed Capital Cost + Levelized Annual O&M cost. Annualized capital cost = Installed capital cost x 0.08718 annualized capital cost factor. Levelized annual O&M cost = Annual O&M cost x 1.24873 annualized O&M cost factor.

(6) - Average Control Cost Effectiveness ($/ton) is the Levelized Total Annual Cost ($/yr) divided by Annual Emission Reduction (tons). All cost figures in 2006 dollars.

(7) - The inclusion of tail-end and low-dust SCR technologies in this table does not constitute agreement that it is technically feasible to install these technologies on Unit 1 at Milton R. Young Station. The estimated annual NOx removal and LTAC shown for a hypothetically-applied SCR system is based on assumptions that known or expected reasons for technical infeasibility for installation and operation and maintenance of the SCR equipment on this boiler are solvable. SCR technology is considered technically infeasible by Minnkota for application at MRYS per the October 2006 NO$_X$ BACT Analysis Study report and subsequent submittals in response to comments by the NDDH, EPA, DOJ, and other parties, so this information for the hypothetical application of SCR alternatives is included for comparative purposes only. See Section 4.2.1.2.1 for details of Scenario A and Scenario B that assumes replacement of SCR catalyst after a specified number of hours of unit operation.

(8) - The stated overall control percentage includes the anticipated long-term emission reduction of 90% design removal from a baseline of 0.51 lb/mmBtu resulting from an advanced separated overfire air system, with air-staged low-NO$_X$ cyclone combustion. Without a separated overfire air system operation or any other technique employed, the assumed emission rate would be 0.085 lb/mmBtu, for an overall reduction of 90 percent from a baseline of 0.849 lb/mmBtu.

(9) - LTAC for reburn options include high-pressure natural gas supply pipeline annualized capital cost of $704,000/yr for CGR and $352,000 for FLGR; LTAC for increased PM collection capacity included in lignite reburn option are $2,054,000 for annualized capital cost plus $2,384,000/yr for annualized O&M cost, for a total of $4,438,000/yr.

TABLE 4-9SF – Estimated Emissions and Economic Impacts Summary for NO_X Control Alternatives - MRY Station Unit 1 – Shared Facilities SCR Projects

Summary of Estimated Annual Emissions and Economics for NOx Control Alternatives Evaluated for Milton R. Young Station Unit 1 – Shared Facilities Projects

		EMISSIONS(2)					ECONOMIC IMPACTS			
Alt. Label(1)	NOx Control Alternative	Emission Rate lb/mmBtu	Hourly Emission lbs/hr	Annual Emission tons/yr	Emission Reduction tons/yr	NOx Removal Efficiency(2) %	Installed Capital Cost(3) $1,000	Annual O & M Cost(4) $1,000	Levelized Total Annualized Cost(5) $1,000	Average Control Cost(6) $/ton

	Baseline	0.849	2,330	9,934	0	0.0	0	0	0	

(1) - Alternative label has been assigned from highest to lowest unit NOx emission rate.

(2) - Estimated NO_X control level reductions relative to average annual unit emission baseline of 0.849 lb/mmBtu at 2,744 mmBtu/hr MCR heat input. Emissions are calculated from unit emission rates, control percentage, hourly heat input, and annual hrs/yr operation compared to pre-control baseline based on annual operation at a gross unit electrical output of 244.45 MWg and assumes a 97.3% average annual availability. Values from reported emission data for the 12 month operating period during 2001-2005 with the highest rolling summation of NOx pounds.

(3) - Installed capital cost is estimated for determination of total capital cost for a particular technology or combination, assuming 257 MWg unit capacity rating. All cost figures in 2006 dollars. Costs for gas reburn options include high-pressure natural gas supply pipeline installed capital cost of $8,075,000 for CGR and $4,038,000 for FLGR. Costs for increased PM collection capacity included in lignite reburn option are $23,561,000 for installed capital cost.

(4) - Annual operating and maintenance cost for a particular technology or combination is compared to unit baseline operation at a gross unit electrical output of 244.45 MWg and assumes a 96.6% average running plant capacity ratio compared to nominal unit gross electrical output capacity of 253 MWg. All cost figures in 2006 dollars. Costs for increased PM collection capacity included in lignite reburn option are $1,909,000/yr for annual O&M cost.

(5) - Levelized Total Annual Cost = Annualized Installed Capital Cost + Levelized Annual O&M cost. Annualized capital cost = Installed capital cost x 0.08718 annualized capital cost factor. Levelized annual O&M cost = Annual O&M cost x 1.24873 annualized O&M cost factor.

(6) - Average Control Cost Effectiveness ($/ton) is the Levelized Total Annual Cost ($/yr) divided by Annual Emission Reduction (tons). All cost figures in 2006 dollars.

(7) - The inclusion of tail-end and low-dust SCR technologies in this table does not constitute agreement that it is technically feasible to install these technologies on Unit 1 at Milton R. Young Station. The estimated annual NOx removal and LTAC shown for a hypothetically-applied SCR system is based on assumptions that known or expected reasons for technical infeasibility for installation and operation and maintenance of the SCR equipment on this boiler are solvable. SCR technology is considered technically infeasible by Minnkota for application at MRYS per the October 2006 NO_X BACT Analysis Study report and subsequent submittals in response to comments by the NDDH, EPA, DOJ, and other parties, so this information for the hypothetical application of SCR alternatives is included for comparative purposes only. See Section 4.2.1.2.1 for details of Scenario A and Scenario B that assumes replacement of SCR catalyst after a specified number of hours of unit operation.

(8) - The stated overall control percentage includes the anticipated long-term emission reduction of 90% design removal from a baseline of 0.51 lb/mmBtu resulting from an advanced separated overfire air system, with air-staged low-NO_X cyclone combustion. Without a separated overfire air system operation or any other technique employed, the assumed emission rate would be 0.085 lb/mmBtu, for an overall reduction of 90 percent from a baseline of 0.849 lb/mmBtu.

(9) - LTAC for reburn options include high-pressure natural gas supply pipeline annualized capital cost of $704,000/yr for CGR and $352,000 for FLGR; LTAC for increased PM collection capacity included in lignite reburn option are $2,054,000 for annualized capital cost plus $2,384,000/yr for annualized O&M cost, for a total of $4,438,000/yr.

The other elements of the fourth step of a BACT analysis following economic impacts are to evaluate the following impacts of feasible emission controls:

(1) The energy impacts.
(2) The environmental impacts.

4.2.2 ENERGY IMPACTS OF HYPOTHETICALLY-APPLIED SCR NO_X CONTROL ALTERNATIVES FOR MRY STATION UNIT 1

Operation of the NO_X control technologies on the dominant controls cost curve for potential application at the Milton R. Young Station impose direct impacts on the consumption of energy required for the production of electric power at the facility. The details of estimated energy usage and costs for the previously-evaluated NO_X control alternatives were described and summarized in Section 3.4.2 and Appendix C3 of the October 2006 NOx BACT Analysis Study report[39].

The hypothetical application of Tail End and Low-Dust SCR w/ ASOFA alternatives involve higher energy consumption compared with the existing operation of MRYS Unit 1. New induced draft booster fan electrical power demand is needed due to the estimated additional flue gas pressure drop resulting from hypothetical application of SCR reactor, ductwork, and gas-to-gas heat exchangers. The additional auxiliary electric power demand for the hypothetical application of TESCR and LDSCR equipment were calculated to be 9.7 MW and 8.0 MW, respectively, using estimated annual average electrical loads of the booster fan, urea-to-ammonia conversion fired heater combustion/dilution air fan, direct-fired flue gas reheat burner combustion air fan, and service and sootblowing air compressor equipment and related auxiliary equipment.

Preliminary conceptual design details were developed for these alternatives. An estimated additional 12 inches w.c. of flue gas pressure drop was assumed for each hypothetical application of low-dust SCR system, and an estimated additional 19 inches w.c. of flue gas pressure drop was assumed for the hypothetical application of tail end SCR system. Equipment and ductwork arrangements and expected fouling of the catalyst for the hypothetical application of SCR system ductwork, reactor, and gas-gas reheater changes may cause significantly more restrictive flow paths. Thus the electrical power usage estimated here may be too low.

---

[39] Ibid Reference number 3, October 2006, pages 3-31 through 3-35, and Appendix pages C3-7 through C3-10.

The expected loss of electrical power generation from these reductions in net output was included as a cost, assuming $35 per megawatt-hour for replacement electrical power. Energy impacts of installing hypothetical application of low-dust and tail end SCR alternatives for NO_X control were included in the O&M cost section (4.2.1.2.1) of this supplemental analysis as Tables C.4-2 through C.4-4.

Aqueous urea solution was assumed to be the preferred, readily available and transportable source of the amine reagent needed to supply ammonia to the SCR reactor catalyst for the low-dust and tail-end SCR alternatives. A urea-to-ammonia conversion system dedicated for each SCR reactor was also assumed. This conversion process will use a natural gas-fired burner that mixes the combustion products at high temperature with the injected aqueous urea solution to thermally decompose the urea, producing gaseous ammonia to supply to the reactors' ammonia injection grids. Gaseous ammonia is the required amine reagent that the catalyst in the SCR reactors uses to convert nitrogen oxides to elemental nitrogen and water vapor. Ammonia (from urea conversion) is supplied and consumed continuously on demand while the SCR NO_X reduction process is in operation. Natural gas is fired continuously during the urea-to-ammonia conversion system operation.

Final reactor inlet flue gas reheat systems are required for the hypothetical application of tail end and low-dust SCR with ASOFA alternatives. A natural gas-fired duct burner that injects high temperature combustion products directly into the flue gas discharged from each SCR gas/gas heat exchanger was assumed for raising the reactor inlet temperature to 600ºF before ammonia injection and NOx reduction can occur in each SCR reactor. Natural gas is fired continuously for flue gas reheating during SCR system operation.

TABLE 4-10 – Energy Impacts for NO$_X$ Control Alternatives - MRY Station Unit 1

A	Advanced SOFA (ASOFA)	0	0	0	0	0

(1) - Alternative label has been assigned from highest to lowest unit NOx emission rate. Alternatives are labeled the same as in Table 4-9.

(2) - The inclusion of tail-end and low-dust SCR technologies in this table does not constitute agreement that it is technically feasible to install these technologies on Unit 1at Milton R. Young Station. The annual NOx removal and LTAC shown for a hypothetically-applied SCR system is based on assumptions that known or expected reasons for technical infeasibility for installation of the SCR equipment on this boiler are solvable. SCR technology is considered technically infeasible by Minnkota for application at MRYS per the October 2006 NO$_X$ BACT Analysis Study report and subsequent submittals in response to comments by the NDDH, EPA, DOJ, and other parties, so this information for the hypothetical application of SCR alternatives is included for comparative purposes only. See Section 4.2.1.2.1 for details of Scenario A and Scenario B that assumes replacement of SCR catalyst after a specified number of hours of unit operation.

(3) – Estimated annual natural gas usage for urea-to-ammonia conversion based on adjustments to preliminary budgetary equipment vendor proposals and process calculations. TESCR and LDSCR rate = 4.27 mmBtu/hr for one reactor.

(4) – Estimated annual natural gas usage for flue gas final reheat based on adjustments to preliminary vendor process calculations. TESCR rate = 60.3 mmBtu/hr for one reactor; LDSCR rate = 31 mmBtu/hr for one reactor.

(5) – Natural gas burned for reburn alternatives is assumed to replace coal, no boiler heat rate penalty assumed. Lignite reburn is assumed to burn the same total amount of coal in the boiler as without coal reburn.

(6) - Additional coal burned is due to the urea dilution water injected directly into the boiler’s upper furnace, decreasing heat available for steam production and electricity generation, at a net loss of 900 Btu/lb of water for evaporation. See Appendix C3 in the 2006 NO$_X$ BACT Analysis Study report for additional details.

(7) - Annual O&M costs include these values multiplied by the number of hours per year of operation and assume $7.98 per mmBtu for natural gas and $0.71 per mmBtu for coal.

4.2.3 ENVIRONMENTAL IMPACTS OF HYPOTHETICALLY-APPLIED SCR NO_X CONTROL ALTERNATIVES FOR MRY STATION UNIT 1

Operation of the NO_X control technologies on the dominant controls cost curve for potential application at the Milton R. Young Station would impose direct and indirect impacts on the environment. The most pronounced direct environmental impact expected from operation of any of the NO_X control options considered is the reduction of ozone and improvement in atmospheric visibility (i.e., reduced visibility impairment) downwind of the facility. Environmental impacts of previously-evaluated NO_X control alternatives were described and summarized in Section 3.4.3 of the October 2006 NOx BACT Analysis Study report.[40]

There would be a favorable environmental impact from potential reduction of annual unit operating time by approximately two percent due to cyclone slag issues associated with air-staged cyclones/ASOFA system operation and by between five percent and 17 percent due to catalyst management and SCR equipment maintenance-related issues for the various low-dust and tail end SCR alternatives. The impact of fewer annual hours of operation will be to decrease the annual amount (tons) of nitrogen oxides emitted, by between approximately 0.2 percent and one percent overall compared to baseline operation. However, generation of replacement electrical power at other powerplants will negate most of these emission reductions.

Operation of the hypothetical application of SCR systems is not expected to significantly impact emissions of carbon monoxide (CO) or volatile organic compounds (VOCs). Emissions from the urea-to-ammonia conversion and flue gas reheat natural gas-fired burners are additive and included in the flue gas entering the SCR reactor in each hypothetical application of SCR case.

Operation of any SCR system will normally cause a small amount of unreacted ammonia to be emitted. The amount of ammonia slip produced by an SCR depends on the reagent utilization and the location of the injection points. Higher SCR NO_X reduction performance involves greater amounts of reagent usage and ammonia slip. This is typically controlled to less than 2 ppmvd, especially when the possible formation of sulfates such as ammonium sulfate $[(NH_4)_2SO_4]$ and ammonium bisulfate $[NH_4HSO_4]$ will be more problematic at higher slip levels. Sulfur trioxide (SO_3) formed during combustion in the boiler can combine with ammonia during passage through the catalyst to form the sulfates downstream.

---

[40] Ibid Reference number 3, October 2006, pages 3-35 through 3-37.

Unreacted ammonia (“slip”) from SCR operation will not be collected downstream of the tail end SCR reactor. The wet flue gas desulfurization absorber downstream of the low-dust SCR reactor may reduce ammonia slip. Any remaining ammonia slip that is not collected or condensed in the air pollution control system will be emitted from the stack as an aerosol or condensable particulate. This has the potential to increase atmospheric visibility impairment downwind of the facility compared with a pristine condition.

Sulfur dioxide (SO_2) formed during combustion in the boiler can combine with oxygen during passage through the hypothetical application of tail end and low-dust SCR catalyst to form additional sulfur trioxide (SO_3) emissions. SO_3 can subsequently combine with water (H_2O) to form sulfuric acid (H_2SO_4), usually in the form of a mist. Wet flue gas scrubbing to remove SO_2 is not highly effective in removing SO_3 created in an upstream low-dust SCR, so higher sulfate emissions will result unless a precipitating reaction with ammonia or condensation in the downstream gas-gas reheater or ductwork occurs. SO_3 and H_2SO_4 can have significant negative far-field impairment impacts on atmospheric visibility if they are above threshold concentrations and not controlled. Tail end SCRs can also cause a small amount of SO_3 to be created as the remaining SO_2 not removed by the wet lime flue gas desulfurization systems will pass through the catalyst and some will be oxidized. It is not known whether the high concentration of alkalinity in the form of sodium aerosol particles will effectively eliminate the remaining SO_3 downstream of the low-dust and tail end SCR systems.

Catalyst from the hypothetical application of SCR reactors will require regular replacement, requiring disposal of the spent catalyst materials or chemical cleaning to remove deposits to allow reuse or regeneration. Hauling spent catalyst to a catalyst rejuvenation facility or an authorized landfill may be required, producing additional liquid and solid wastes and vehicle exhaust emissions.

Because railroad service is not available to MRYS, shipments of amine reagent (concentrated urea solution) for consumption by the hypothetical application of SCR reactors will require additional truck traffic between the supply facility and plant, producing more emissions from vehicle exhaust.

4.2.4 SUMMARY OF ECONOMIC, ENERGY AND ENVIRONMENTAL IMPACTS OF HYPOTHETICALLY-APPLIED SCR NO_X CONTROL ALTERNATIVES FOR MRY STATION UNIT 1

The economic, energy, and environmental impacts of each NO_X control technology on the dominant controls cost curve for potential application at the Milton R. Young Station evaluated for this study are summarized in this Section. Table 3-18 summarized the various impacts discussed in Sections 3.4.1 through 3.4.3 of the October 2006 NO_X BACT Analysis Study report[41]. This supplemental economic analysis examined the estimated capital cost of four hypothetically-applied SCR cases and previously-analyzed feasible NO_X control alternatives and any other powerplant upgrade costs necessary to implement the alternatives. In addition, the economic analysis examined the operating and maintenance costs associated with each NO_X control technology evaluated. These costs were then combined into the levelized total annual cost for a comparative assessment of the total implementation cost of each alternative. Finally, as part of the top-down analysis, a dominant controls cost curve was plotted and the unit control cost for each remaining alternative was evaluated. Four hypothetically-applied SCR cases and two previously-analyzed feasible alternatives were on the dominant controls cost curve and the latter were identified as the more cost effective alternatives. The four hypothetically-applied SCR cases and two previously-analyzed feasible BACT NO_X control alternatives were evaluated for incremental cost, energy, and environmental impacts applicable to Milton R. Young Station Unit 1. The results are summarized in Tables 4-11SA and 4-11SF.

The unit control cost for the hypothetical application of Scenario A Tail End SCR w/ ASOFA case was $4,758/ton and was $5,969/ton for the hypothetical application of Scenario B Tail End SCR w/ ASOFA case (stand alone projects). The unit control cost for the hypothetical application of Scenario A Low-Dust SCR w/ ASOFA case was $3,944/ton and was $5,380/ton for the hypothetical application of Scenario B Low-Dust SCR w/ ASOFA case (stand alone projects). The unit control cost for the hypothetical application of Scenario A Tail End SCR w/ ASOFA case was $4,206/ton and was $5,420/ton for the hypothetical application of Scenario B Tail End SCR w/ ASOFA case (shared facilities projects). The unit control cost for the hypothetical application of Scenario A Low-Dust SCR w/ ASOFA case was $3,396/ton and was $4,835/ton for the hypothetical application of Scenario B Low-Dust SCR w/ ASOFA case (shared facilities projects). Unit control cost for SNCR w/ ASOFA was $1,265/ton, more than twice that of ASOFA ($613/ton). The UCCs for the hypothetical application of SCR are approximately 270 to 470 percent of the UCC for SNCR w/ ASOFA ($1,265/ton), and approximately 550 to 970 percent of ASOFA's UCC ($613/ton).

The incremental cost analysis indicates that from a cost effectiveness viewpoint, the SNCR with ASOFA alternative for MRYS Unit 1 incurs a significant annual (levelized) incremental cost compared to the ASOFA NO_X control technique. The slope from zero (baseline) to ASOFA (Point A) was $613/ton; the

---

[41] Ibid Reference number 3, October 2006, pages 3-20 through 3-38.

incremental cost per ton (slope) from ASOFA (Point A) to SNCR with ASOFA (Point E) was $2,694/ton for MRYS Unit 1. The incremental cost per ton (slope) from SNCR with ASOFA (Point E) to the top hypothetical application of low-dust SCR case (Point L2, Scenario A) was $8,547/ton (stand alone projects). The incremental cost per ton (slope) from SNCR with ASOFA (Point E) to the top hypothetical application of tail end SCR case (Point T2, Scenario A) was $10,765/ton (stand alone projects). The incremental cost per ton (slope) from SNCR with ASOFA (Point E) to the second hypothetical application of low-dust SCR case (Point L1, Scenario B) was $12,343/ton (stand alone projects). The incremental cost per ton (slope) from SNCR with ASOFA (Point E) to the second hypothetical application of tail end SCR case (Point T1, Scenario B) was $13,936/ton (stand alone projects). For shared projects, the incremental cost per ton (slope) from SNCR with ASOFA (Point E) to the top hypothetical application of SCR cases were $7,058/ton (low-dust Point L2, Scenario A) and $9,264/ton (tail end Point T2, Scenario A). For shared projects, the incremental cost per ton (slope) from SNCR with ASOFA (Point E) to the second hypothetical application of SCR cases were $10,876/ton (low-dust, Point L1, Scenario B) and $12,458/ton (tail end Point T1, Scenario B).

The incremental unit control cost per ton (slope) from SNCR with ASOFA to the hypothetical application of SCR with ASOFA cases are approximately 260 to 520 percent of the incremental UCC per ton (slope) between ASOFA and SNCR with ASOFA ($2,694/ton). The incremental UCCs from SNCR with ASOFA to the hypothetical application of SCR with ASOFA cases is between 11 and 23 times the incremental UCC for ASOFA from the pre-control baseline ($613/ton).

In the U.S. EPA’s NSR Manual, the EPA does not specify acceptable or unacceptable ranges for average (unit control costs) and incremental cost effectiveness values. EPA’s NSR Manual however, does specifically address the standard to be used when rejecting a candidate technology on the basis of adverse economic impact:

> “Consequently, where unusual factors exist that result in cost/economic impacts beyond the range normally incurred by other sources in that category, the technology can be eliminated provided the applicant has adequately identified the circumstances, including the cost or other analyses, that show what is significantly different about the proposed source.”[42]

This supplemental report for the MRYS NOx BACT Analysis has clearly established the circumstances, including the economic impacts, which would make the hypothetical application of TESCR or LDSCR to

---

[42] Ibid Reference number 2, Section IV.D.2.c.

MRYS Unit 1 significantly more expensive than SCR costs normally incurred by other coal-fired steam electric generating units. The following information further supports EPA's own statements regarding the costs "normally incurred by other sources". The EPA's technical support document issued with the final Regional Haze Regulations and BART Guidelines was considered relevant for control cost-effectiveness comparison. The EPA's cost-effectiveness analysis used for establishing presumptive BART stated that "applying SCR for coal-fired cyclone units is typically less than $1500 a ton, and that the average cost-effectiveness is $900 per ton" [43]. EPA's technical support document estimated an average control cost for SCR applied to MRYS Unit 1 of $549 per ton[44]. The unadjusted unit capital cost factor assumed by the EPA for SCR retrofits applied to cyclone boilers in the cost-effectiveness analysis used for establishing presumptive BART[45] was $100/kW. The estimated "stand alone" and "shared facilities" installed capital costs for the hypothetical application of Low-Dust SCR w/ ASOFA cases at MRYS Unit 1 are $543 to $703/kW, which is more than 500 percent of the EPA's number. The estimated "stand alone" and "shared facilities" installed capital costs for the hypothetical application of Tail End SCR w/ ASOFA cases are $706 to $867/kW, which is more than 700 percent of the EPA's number. Also stated in the final RHR/BART Guidelines, "the average cost for each [of two options, A and B]… may be deemed to be reasonable. However, the incremental cost…of the additional emissions reductions to be achieved by control B may be very great. In such an instance, it may be inappropriate to chose control B, based on its higher incremental costs, even though its average cost may be considered reasonable".[46]

4.2.5 CONCLUSIONS

The site-specific control costs estimated for application of hypothetical application of tail-end and low-dust SCR alternatives to MRYS Unit 1 are significantly higher than the EPA's cost-effectiveness analysis for conventional SCR technologies included in the technical support document issued with the final Regional Haze Regulations and BART Guidelines discussed above.

The expected severity of catalyst blinding and pluggage from particulate matter and flue gases emitted from cyclone-fired boilers burning North Dakota lignite precludes the technical feasibility for successful application of such SCR technologies on the electric generating units (EGUs) at the Milton R. Young Station. Not withstanding the technical discussion of SCR technology infeasibility and technical details

[45] Ibid Reference number 4, June 2005, Excel Spreadsheet OAR-2002-0076-0446, page 209.
[46] Ibid Reference number 11, July 2005, FR Vol. 70 No. 128, page 39168.

previously provided in Appendix A1 and Appendix B[47] of the initial NO_X BACT Analysis report and subsequent submittals in response to comments by the NDDH, EPA, DOJ, and other parties, this supplemental analysis concludes that the estimated capital and O&M costs for four variations of hypothetically-applied tail-end and low-dust SCR technology alternatives are significantly beyond the normal range of costs incurred, as compared to cost analysis values included in EPA's technical support document issued with the final Regional Haze Regulations and BART Guidelines[48,49]. Average control cost effectiveness for each hypothetical application of SCR control technology case is a minimum of approximately three times the unit control costs of the previously-analyzed highest-performing feasible control alternative recommended as BACT for MRYS Unit 1 (SNCR with ASOFA). Incremental control cost effectiveness for each hypothetical application of SCR control technology case is a minimum of approximately three times the incremental control costs of the previously-analyzed highest-performing feasible control alternative recommended as BACT for MRYS Unit 1 (SNCR with ASOFA).

There is an expected decrease in capacity and availability to generate electrical power due to the hypothetical application of low-dust and tail end SCR alternatives. A five to 17 percent decrease in the number of hours of annual operation, and approximately 3% drop in annual plant capacity (net electrical output or MW_n) during operation of the MRYS Unit 1 system are expected if the hypothetical application of low-dust or tail end SCR alternatives were installed. There are also substantial expected negative energy impacts for each hypothetical application of SCR control technology case. Additional auxiliary electrical power demands of approximately 8 to 10 MW will result. This estimate of electrical power usage may be too low. This higher electrical power consumption and lower electrical power generation by MRYS Unit 1 will require additional replacement electrical power to be generated elsewhere.

Natural gas is fired continuously during the urea-to-ammonia conversion system operation for the hypothetical application of Tail End and Low-Dust SCR with ASOFA alternatives.

Final reactor inlet flue gas reheat systems are required for the hypothetical application of Tail End and Low-Dust SCR with ASOFA alternatives. Natural gas is fired continuously for flue gas reheating during SCR system operation for raising the reactor inlet temperature to 600ºF before ammonia injection and NOx reduction can occur in the SCR reactor.

[47] Ibid Reference number 3, October 2006.
[48] See Reference number 11, July 2005, FR Vol. 70 No. 128, pages 39135 and 39136.
[49] Ibid Reference number 4, June 2005, Excel Spreadsheet OAR-2002-0076-0446, page 215.

The site-specific control costs estimated for application of hypothetical application of tail-end and low-dust SCR alternatives to MRYS Unit 1 are significantly higher than the EPA's cost-effectiveness analysis for conventional SCR technologies included in the technical support document issued with the final Regional Haze Regulations and BART Guidelines[50]. SCR technologies of all three types identified in the October 2006 NO_X BACT Analysis Study report should be excluded from consideration for NO_X control at MRYS due to unacceptably high average and incremental cost per ton of pollutant removal based on the supplemental analysis provided herein. Therefore the conclusions regarding NOx BACT as expressed in the original October 2006 BACT Analysis for MRYS Unit 1 are confirmed.

The economic, energy, and environmental impacts of each NO_X control technology on the dominant controls cost curve for potential application to Unit 1 at the Milton R. Young Station evaluated for this study are summarized in Tables 4-11SA and 4-11SF.

TABLE 4-11SA – Summary of Supplemental BACT Analysis Impact Results for Dominant NO_X Control Alternatives - MRY Station Unit 1 - Stand Alone SCR Projects

		EMISSIONS(2)				ECONOMIC IMPACTS					ENERGY IMPACTS		ENVIRONMENTAL IMPACTS(9)	
Alt. Label(1)	NOx Control Alternative	Emission Rate lb/mmBtu	Hourly Emission lbs/hr	Annual Emission tons/yr	Emission Reduction tons/yr	Installed Capital Cost(3) $1,000	Annual O & M Cost(4) $1,000	Levelized Total Annualized Cost(5) $1,000	Average Control Cost(6) $/ton	Incremental Control Cost(7) $/ton	Incremental Aux. Power Demand(8), kW	Incremental Annual Aux. Power Usage + Generation Reduction(8), kW-hrs/yr	Non-Air Increase	Toxic Air Increase
T2	Hypothetical Tail End SCR w/ ASOFA – Scenario A(10)	0.053	145	589	9,345	222,864	20,048	44,465	4,758	10,765	9,685	171,745,369	Flyash UBC, catalyst disposal	CO, NH_3
T1	Hypothetical Tail End SCR w/ ASOFA – Scenario B(10)	0.053	145	536	9,398	222,864	29,361	56,095	5,969	13,936	9,685	342,358,537	Flyash UBC, catalyst disposal	CO, NH_3
L2	Hypothetical Low-Dust SCR w/ ASOFA – Scenario A(10)	0.053	145	586	9,348	180,739	16,908	36,872	3,944	8,547	8,012	169,418,356	Flyash UBC, catalyst disposal	CO, NH_3
L1	Hypothetical Low-Dust SCR w/ ASOFA – Scenario B(10)	0.053	145	533	9,401	180,739	27,882	50,575	5,380	12,343	8,012	341,140,028	Flyash UBC, catalyst disposal	CO, NH_3
E	SNCR w/ ASOFA	0.355	975	4,025	5,909	8,113	5,417	7,472	1,265	2,694	73	68,243,017	Flyash UBC	CO, NH_3
A	Advanced SOFA (ASOFA)	0.513	1,409	5,874	4,060	4,277	1,695	2,489	613	613	1	46,594,605	Flyash UBC	CO
	Baseline	0.849	2,330	9,934	0	0	0	0						

(1) - Alternative label has been assigned from highest to lowest unit NOx emission rate.

(2) - Estimated NO_X control level reductions relative to average annual emission baseline of 0.849 lb/mmBtu at 2,744 mmBtu/hr heat input. Emissions are calculated from unit emission rates, control percentage, hourly heat input, and annual hrs/yr operation compared to pre-control baseline based on annual operation at a gross unit electrical output of 244.5 MWg and assumes a 97.3% average annual availability.

(3) - Installed capital cost is estimated for determination of total capital cost for a particular technology or combination, assuming 257 MWg unit capacity rating. All cost figures in 2006 dollars.

(4) - Annual operating and maintenance cost for a particular technology or combination is compared to unit baseline operation at a gross unit electrical output of 244.5 MWg and assumes a 97.3% average annual availability, which is the highest consecutive 12-months of operation from 2001-2005. All cost figures in 2006 dollars.

(5) - Levelized Total Annual Cost = Annualized Installed Capital Cost + Levelized Annual O&M cost. Annualized capital cost = Installed capital cost x 0.08718 annualized capital cost factor. Levelized annual O&M cost = Annual O&M cost x 1.24873 annualized O&M cost factor.

(6) - Average Control Cost Effectiveness ($/ton) is the Levelized Total Annual Cost ($/yr) divided by Annual Emission Reduction (tons/yr). All cost figures in 2006 dollars.

(7) - Incremental Control Cost Effectiveness ($/ton) is the difference in LTAC between the next most stringent alternative divided by the emissions reduction. All cost figures in 2006 dollars.

(8) - Energy impacts are incremental auxiliary electrical power demand (kW) and annual power usage plus generation lost due to negative unit reliability (fewer hours per year of operation) resulting from each control alternative (kW-hrs/yr) compared to the pre-control baseline.

(9) - Environmental impacts summarize expected non-air effects and potential toxic air emissions resulting from control alternative compared to the pre-control baseline. Flyash unburned carbon content may increase with air-staging cyclones; carbon monoxide concentrations may increase an insignificant amount with air-staging cyclones. Excess unreacted ammonia (slip) expected from SNCR technology and the hypothetical application of SCR technology cases.

(10) - The inclusion of tail-end and low-dust SCR technologies in this table does not constitute agreement that it is technically feasible to install these technologies on Unit 1 at Milton R. Young Station. The estimated annual NOx removal and LTAC shown for a hypothetically-applied SCR system is based on assumptions that known or expected reasons for technical infeasibility for installation and operation and maintenance of the SCR equipment on this boiler are solvable. SCR technology is considered technically infeasible by Minnkota for application at MRYS per the October 2006 NO_X BACT Analysis Study report and subsequent submittals in response to comments by the NDDH, EPA, DOJ, and other parties, so this information for the hypothetical application of SCR alternatives is included for comparative purposes only. See Section 4.2.1.2.1 for details of Scenario A and Scenario B that assume replacement of SCR catalyst after a specified number of hours of unit operation.

4.0 SUPPLEMENTAL NOx BACT ANALYSIS CONTROLS & COSTS – MRY STATION UNIT 1

This supplement to the NO_X BACT analysis for Milton R. Young Station (MRYS) Unit 1 has been prepared in response to the request of the North Dakota Department of Health[1]. The NDDH requested completion of a "full" BACT analysis for two specific technologies that had been eliminated at step 2 of the BACT analysis process[2] in the October 2006 NO_X BACT Analysis Study report[3]. These two technologies are low-dust selective catalytic reduction (SCR) and tail-end SCR. The approach taken in this supplemental NO_X BACT Analysis Study report for MRYS Unit 1 includes ranking by effectiveness and providing an impacts analysis of alternate control technologies for NO_X emissions that follows the third and fourth steps of a "top down" BACT analysis as described in the EPA's Draft New Source Review Workshop Manual[4]. The initial NO_X BACT Analysis Study for Milton R. Young Station identified potentially available NO_X control techniques and technologies, summarized in Table 3-3[5] of the October 2006 report. Commonly-applied and novel NO_X control techniques and technologies, including a technical description of the specific emission reduction processes and capabilities, were summarized in Section 3.2[6] and detailed in Appendix A1 of the initial NO_X BACT Analysis Study report. This supplemental analysis report does not include the details of the technical feasibility discussion previously provided in the initial NO_X BACT Analysis Study report for MRYS Unit 1.

SCR technology is considered technically infeasible by Minnkota for application at MRYS, so this information for the hypothetical application of low-dust and tail end SCR alternatives is included for comparative purposes only. Cost estimates and emission rates shown for such hypothetically-applied SCR systems are based on assumptions that known or expected reasons for technical infeasibility for installation, operation and maintenance of the SCR equipment on this boiler are solvable. There is no available information on recently-completed similar tail-end or low-dust SCR projects on coal-fired powerplants in the United States that could be used, with adjustments, to represent total installed costs that could be expected for MRYS Unit 1. Site-specific needs and challenges identified for applying tail end and low-dust SCR technologies to Milton R. Young Station Unit 1 significantly influence the capital cost estimate for variations of these hypothetical applications of SCR alternatives. Furthermore, the

[1] See Reference number 1, July 2009 and August 2009.

[2] As described in the EPA's Draft New Source Review Workshop Manual. See Reference number 2, October 1990.

[3] See Reference number 3, October 2006. This Supplement commences with Section 4.0, which places it at the end of the October 2006 Analysis, which ended at Section 3.5.2.

[4] As described in the EPA's Draft New Source Review Workshop Manual. Ibid Reference number 2, October 1990.

[5] Ibid Reference number 3, October 2006, page 3-5.

[6] Ibid Reference number 3, October 2006, page 3-6 through page 3-13, and pages A1-1 through A1-55.

"EPA Air Pollution Control Cost Manual" is not applicable for use in estimating control equipment costs for these hypothetical applications of SCR technologies, as the EPA Control Cost Manual states:

> "The costs for the tail-end arrangement, however, cannot be estimated from this report because they are significantly higher than the high-dust SCR systems due to flue gas reheating requirements."[7]

This requirement for flue gas reheating also applies to the hypothetical application of low-dust SCR to MRYS, due to the cold-side arrangement (downstream of the electrostatic precipitator) instead of a hot-side ESP assumed in the EPA Control Cost Manual. Therefore, the equations in the EPA Control Cost Manual cannot be used for estimating either of the hypothetical applications of SCR configurations for which NDDH has requested economic analyses. Thus it was necessary to prepare independent site-specific cost estimates.

The site-specific control costs estimated for hypothetical application of tail-end and low-dust SCR alternatives to MRYS Unit 1 are significantly higher than the EPA's cost-effectiveness analysis for conventional SCR technologies included in the technical support document issued with the final Regional Haze Regulations and BART Guidelines[8]. Low-dust and tail end SCR technologies should be excluded from consideration for NO_X control at MRYS due to unacceptably high average and incremental cost per ton of pollutant removal based on the supplemental analysis provided herein. The October 2006 NO_X BACT Analysis Study report, and additional subsequent arguments included in responses to comments by the EPA, Department of Justice (DOJ), NDDH, and other parties[9], also present reasons for technical infeasibility of all SCR technologies considered for application at MRYS not included in this supplemental analysis report. In addition, the fact that catalyst vendors will not guarantee catalyst life on such SCR technologies without successful results from extensive pilot slipstream testing bolsters the previous submitted arguments of technical infeasibility of these NO_X control alternatives at MRYS.

4.0.1 ADDITIONAL NOx CONTROLS

The inclusion of hypothetical emissions control alternatives employing tail-end and low-dust SCR technologies in this supplemental NO_X BACT Analysis Study report does not constitute agreement by

---

[7] See Reference number 10, Section 4.2, Chapter 2, page 2-41, October 2000.
[8] See Reference number 4, June, 2005.
[9] Responses submitted by Minnkota in 2007-2009.

Minnkota that it is technically feasible to install these technologies on Unit 1 at Milton R. Young Station. The rationale for rejection of all forms of SCR technology in this specific case, based on an interpretation of the EPA's Draft New Source Review Workshop Manual[10], has previously been submitted to the North Dakota Department of Health[11] and is not repeated herein. Nevertheless, this supplemental NO_X BACT Analysis Study report has been completed based on the *hypothetical assumption* that these two technologies pass the test for technical feasibility. The development of NO_X emissions control alternatives involving hypothetical application of technologies such as low-dust and tail end SCR systems at MRYS is based on preliminary plant layout design concepts that require pilot-scale slipstream SCR testing and more detailed equipment design for confirmation that all technical infeasibility issues previously raised have been, or can be, satisfactorily resolved. This supplemental analysis includes estimated capital costs and operating and maintenance (O&M) costs for four variations of alternatives involving hypothetical applications of tail-end and low-dust SCR technologies. Cost effectiveness for each hypothetically-applied SCR control technology case was plotted with previously-analyzed feasible control alternatives.

For the techniques and technologies considered for determining MRYS Unit 1 NO_X control cost-effectiveness, estimates were produced for predicted NO_X reductions that represent long-term expectations of the reduction techniques and technologies being presented in the technical analysis. Each evaluated alternative was tabulated and graphed.

It should be noted that as of October 2006, when the initial BACT Analysis Study report was completed, MRYS Unit 1 did not employ combustion-related or post-combustion NO_X emission reduction technology. However, the installation of an advanced form of a separated overfire air system (ASOFA), designed specifically for this boiler, is being implemented for operation starting prior to December 31, 2009. A summary of the available alternate NO_X emission control technologies is discussed below.

4.1 RANK OF NO_X CONTROL OPTIONS BY EFFECTIVENESS

The first step[12] in this supplemental "top-down" BACT evaluation is to determine the expected control effectiveness of the hypothetical application of tail end and low-dust SCR technology alternatives, so that they may be compared and ranked relative to the technically-feasible NO_X control techniques and

[12] Step 3 per the NSR Manual, Ibid Reference 2, October 1990.

technologies included from the initial NO_X BACT Analysis Study report. To do this, we start with the basis for determining the NOx emissions control effectiveness, which is the historic baseline emissions expressed in pounds per million Btu of heat input from the five-year lookback period.

Unit 1 boiler's baseline pre-control emissions at Milton R. Young Station are based upon the same highest rolling 12-month average unit emission rate (lb/mmBtu) and corresponding highest rolling 12-month average gross heat input rate (mmBtu/hr) that were reported in 2001-2005:

- MRYS Unit 1's highest 12-month NO_X mass emissions averaged 0.849 lb/mmBtu at a corresponding average unit heat input rate of 2,744 mmBtu/hr and unit gross electrical output of 244.5 MW_g.
- During this lookback time period, Unit 1 at Milton R. Young Station was typically operated in a base-loaded manner.

4.1.1 ESTIMATING CONTROL-EFFECTIVENESS OF NO_X EMISSIONS CONTROL OPTIONS

The estimated emission control performance for NO_X control techniques and technologies included from the initial NO_X BACT Analysis Study report is assumed to be the same as previously stated in Table 3-7[13]. The expected control effectiveness of the hypothetical application of tail end and low-dust SCR technology alternatives was added to the listing of highest-performing NO_X control alternatives remaining in consideration following the initial technical infeasibility determinations. These alternatives are ranked in declining order of expected emission reduction. These combined control options refer to "advanced" separated overfire air (ASOFA), and include the expected reduction from operating with modestly air-staged cyclone furnaces and relocated lignite drying system vent ports as applied to this Milton R. Young Station cyclone boiler without incurring potential significant negative impacts of this technique. This level of expected NO_X reduction from ASOFA operation is approximately forty percent below the pre-control baseline emissions rate of 0.849 lb/mmBtu.

---

[13] Ibid Reference number 3, October 2006, page 3-18.

TABLE 4-1 – Ranked NO_X Control Options for MRY Station Unit 1 Boiler with Expected Control Performance

Alt. Label(1)	NO_X Control Alternative	Emission Rate (lb/mmBtu)	Control Percentage(2)
T2	Hypothetical Tail-End SCR w/ ASOFA – Scenario A(3)	0.053	93.8(4)
T1	Hypothetical Tail-End SCR w/ ASOFA – Scenario B(3)	0.053	93.8(4)
L2	Hypothetical Low-Dust SCR w/ ASOFA – Scenario A(3)	0.053	93.8(4)
L1	Hypothetical Low-Dust SCR w/ ASOFA – Scenario B(3)	0.053	93.8(4)
E	SNCR (using urea) w/ ASOFA	0.355	58.1
D	Gas Reburn with ASOFA	0.374	56.0
C	Lignite Reburn w/ ASOFA	0.385	54.6
B	Fuel Lean Gas Reburn with ASOFA	0.460	45.9
A	Advanced Separated Overfire Air (ASOFA)	0.513	39.5
-	Baseline	0.849	-

(1) - Alternative designation assigned from highest to lowest unit NOx emission rate.

(2) - Control percentages are relative to an average pre-control emission baseline of 0.849 lb/mmBtu based on annual operation at highest pre-control 12-month rolling NOx summation mass emissions divided by the 12-month heat input summation.

(3) - The inclusion of tail-end and low dust SCR technologies in this table does not constitute agreement that it is technically feasible to install these technologies on Unit 1 at Milton R. Young Station. The emission rate shown for a hypothetically-applied SCR system is based on assumptions that known or expected reasons for technical infeasibility for installation of the SCR equipment on this boiler are solvable. SCR technology is considered technically infeasible by Minnkota for application at MRYS per the October 2006 NOx BACT Analysis Study report and subsequent submittals in response to comments by the NDDH, EPA, DOJ, and other parties, so this information for the hypothetical application of SCR alternatives is included for comparative purposes only. See Section 4.2.1.2.1 for details of Scenario A and Scenario B that assumes replacement of SCR catalyst after a specified number of hours of unit operation.

(4) The stated overall control percentage includes the anticipated long-term emission reduction of 90% design removal from a baseline of 0.51 lb/mmBtu resulting from an advanced separated overfire air system, with air-staged low-NO_X cyclone combustion. Without a separated overfire air system operation or any other technique employed, the assumed emission rate for hypothetically-applied SCR alternatives would be 0.085 lb/mmBtu, for an overall reduction of 90 percent from a baseline of 0.849 lb/mmBtu.

All hypothetical applications of tail-end and low-dust SCR technology alternatives were assumed to achieve a NO_X emission level of 0.053 lb/mmBtu, which is approximately 90% reduction from a 0.51 lb/mmBtu level representing ASOFA when operating modestly air-staged cyclone furnaces with suitable combustion controls.

Hourly mass emission rates for the baseline pre-control condition were calculated by multiplying the unit emission rate (lb/mmBtu) by the average hourly gross heat input rate (mmBtu/hr), both calculated from Unit 1’s highest 12-month NO_X mass emissions and heat inputs during the 5-year lookback period.

Equivalent annual NO_X emissions (tons) were calculated by multiplying the 12-month summation for unit operating hours during the same period as the highest NO_X emissions by the 12-month average mass emission rate (lb/hr) and dividing by 2000 lb/ton.

The annual tons for the control options were calculated by multiplying the alternative's equivalent average annual hourly mass emission rate (lb/h) by the equivalent annual unit operating hours [8,760 h/yr maximum possible operating time, adjusted by an annual uptime (availability) factor]. Scheduled and unplanned maintenance outages are expected to occur due to each hypothetically-applied SCR system. Catalyst cleaning and replacement events have been estimated, with two frequencies showing a range of possible results. Due to the variability and possible severity of fouling characteristics of gaseous and aerosol particulate emissions generated by cyclone combustion of lignite supplied from the Center mine, and the dependency of the fouling within the hypothetically-applied SCR systems on sodium, potassium, sulfur, and ammonia slip emission levels, conditions may occur during operation of the hypothetically-applied SCR systems that exceed the ability to adjust operational practices sufficiently to avoid forced outages to remove the deposits or prevent significant catalyst deactivation. Table C.4-1 in Section 4.2.1.2.1 includes estimated unit availability and corresponding operating time and outage time due to the four hypothetical applications of SCR technology cases, along with the ASOFA and baseline numbers from the referenced Appendix C3 of the initial NO_X BACT Analysis Study report[14]. Based on these calculations, the estimated annual emissions for M.R. Young Station Unit 1 and the emission reduction corresponding to each technology alternative are shown in Table 4-2.

---

TABLE 4-2 – Expected Annual NO_X Control Performance for MRY Station Unit 1 Alternatives

		EMISSIONS				
Alt. Label(1)	**NOx Control Alternative**	**Emission Rate lb/mmBtu**	**Hourly Emission(2) lbs/hr**	**Annual Emission(3) tons/yr**	**Emission Reduction(4) tons/yr**	**NOx Removal Efficiency(5) %**
T2	Hypothetical Tail End SCR w/ ASOFA– Scenario A(6)	0.053	145	589	9,345	93.8(7)
T1	Hypothetical Tail End SCR w/ ASOFA– Scenario B(6)	0.053	145	536	9,398	93.8(7)
L2	Hypothetical Low-Dust SCR w/ ASOFA – Scenario A(6)	0.053	145	586	9,348	93.8(7)
L1	Hypothetical Low-Dust SCR w/ ASOFA – Scenario B(6)	0.053	145	533	9,401	93.8(7)
E	SNCR (using urea) w/ ASOFA	0.355	975	4,025	5,909	58.1
D	Gas Reburn w/ ASOFA	0.374	1,025	4,275	5,659	56.0
C	Lignite Reburn w/ ASOFA	0.385	1,058	4,343	5,591	54.6
B	Fuel Lean Gas Reburn w/ ASOFA	0.460	1,261	5,260	4,674	45.9
A	Advanced Separated Overfire Air (ASOFA)	0.513	1,409	5,874	4,060	39.5
-	Baseline	0.849	2,330	9,934	0	-

(1) - Alternative label has been assigned from highest to lowest unit NOx emission rate.

(2) - Hourly NO_X emission estimates (lb/hr) were calculated based upon average annual unit emission rate (lb/mmBtu) x 2,744 mmBtu/hr heat input.

(3) - Estimated annual emission tons assume an annual unit availability factor specific to each alternative; 97.3% was assumed for the baseline case. See Appendix C3 of the October 2006 NO_X BACT Analysis Study report. Hypothetical application of tail end SCR case T2 assumes an annual unit availability factor of 92.8% (approx. 8,127 operating hours per year) and case T1 assumes an annual unit availability factor of 84.5% (approx. 7,402 operating hours per year). Hypothetically-applied low-dust SCR case L2 assumes an annual unit availability factor of 92.3% (approx. 8,084 operating hours per year) and case L1 assumes an annual unit availability factor of 84.0% (approx. 7,359 operating hours per year).

(4) - Estimated annual tons of emission reduction is the difference between annual baseline tons and each alternative's annual emissions (tons).

(5) - Estimated NO_X control level percentage reductions relative to 0.849 lb/mmBtu emission baseline at 2,744 mmBtu/hr MCR heat input.

(6) - The inclusion of tail-end and low dust SCR technologies in this table does not constitute agreement that it is technically feasible to install these technologies on Unit 1 at Milton R. Young Station. The emission rate shown for a hypothetically-applied SCR system is based on assumptions that known or expected reasons for technical infeasibility for installation and operation and maintenance of the SCR equipment on this boiler are solvable. SCR technology is considered technically infeasible by Minnkota for application at MRYS per the October 2006 NOx BACT Analysis Study report and subsequent submittals in response to comments by the NDDH, EPA, DOJ, and other parties, so this information for the hypothetical application of SCR alternatives is included for comparative purposes only. See Section 4.2.1.2.1 for details of Scenario A and Scenario B that assume replacement of SCR catalyst after a specified number of hours of unit operation.

(7) - The stated overall control percentage includes the anticipated long-term emission reduction of approximately 90% design removal from a baseline of 0.51 lb/mmBtu resulting from an advanced separated overfire air system, with air-staged low-NO_X cyclone combustion. Without a separated overfire air system operation or any other technique employed, the assumed emission rate for hypothetically-applied SCR alternatives would be 0.085 lb/mmBtu, for an overall reduction of 90 percent from a baseline of 0.849 lb/mmBtu.

4.2 NO_X CONTROLS ANALYSIS AND IMPACTS EVALUATION

The next step[15] of this supplemental “top-down” BACT analysis is to evaluate the impacts of the hypothetical application of SCR alternatives’ NO_X emission controls. Energy, economic, and environmental impacts are to be considered in the control technology evaluation. The purpose of the evaluation is to determine if there are any energy, economic or environmental impacts that would eliminate the top control technologies from consideration.

This evaluation of the effectiveness of the hypothetically-applied SCR alternatives, as well as that of the other control technologies previously considered technically feasible, was performed prospectively, i.e., assuming that none of the control technologies has been implemented. This approach assumes that the hypothetical application of SCR technology cases are considered to have been added to the previous NO_X BACT Analysis Study report submitted in October, 2006. The actual costs incurred for an installed advanced separated overfire air system, or firm price equipment quotes with performance guarantees for SNCR alternatives, have not been used to adjust the control effectiveness or cost impacts of the previously analyzed control alternatives. The approach taken in this supplemental analysis use installed capital costs estimated in calendar year 2009 escalated to project completion forecast in 2018 adjusted to calendar year 2006 basis for the hypothetically-applied tail end SCR and low-dust SCR technology cases that have been added to the list of alternatives previously evaluated.

4.2.1 NO_X CONTROL ECONOMIC IMPACTS FOR MRY STATION UNIT 1

An evaluation was performed to determine the various cost impacts of installing previously-analyzed feasible NO_X control alternatives and the hypothetical application of low-dust and tail end SCR technologies on Milton R. Young Unit 1. This evaluation includes estimated:

- Capital costs;
- Fixed and variable operating and maintenance costs; and
- Levelized total annual costs

to engineer, design, procure, construct, install, startup, test, and place into commercial operation the particular control technology. The results of this evaluation are summarized in Tables 4-3 through 4-11.

---

[15] Step 4 per the NSR Manual, Ibid Reference 2, October 1990.

4.2.1.1 CAPITAL COST ESTIMATES FOR NO_X CONTROL ALTERNATIVES

The range of estimated capital costs to implement some of the various NO_X control technologies were derived from unit output capital cost factors ($/kW) published in technical papers discussing those control technologies. For MRY Station Unit 1, for the cases involving the use of advanced separated overfire air and SNCR alternatives, preliminary project cost estimates using vendor budgetary cost information were developed and used in place of, or to adjust, the published unit output cost factors. A discussion of the reburn alternatives' estimated capital costs was included in the 2006 NO_X BACT Analysis Study report and has not been repeated here. These cost estimates were considered to be study grade, which is + or – 30% accuracy.

For the hypothetical application of low-dust and tail end SCR alternatives at MRYS, there is no available information on recently-completed similar projects on coal-fired powerplants in the United States that could be used, with adjustments, to properly represent total installed costs that could be expected for MRYS Unit 1. For these alternatives, site-specific detailed preliminary (conceptual) designs were developed and budgetary cost information for major equipment was obtained for the development of the estimated installed capital cost.

The unit nameplate output capacity (gross electrical output in megawatts) assumed for the installed capital cost estimate basis of the NO_X control technologies evaluated was 257 MW_g for MRY Station Unit 1[16].

A review of the unit capital cost factor range and single point factors applicable to MRY Station Unit 1 NO_X control technologies are presented in Tables 4-3SA and 4-3SF. Note that the capital cost estimates for the hypothetical application of SCR alternatives were developed separately based on two different assumptions. In one case it was assumed that all costs for the hypothetically-applied Unit 1 SCR (tail end or low-dust) system would be accounted for as if the SCR equipment were being provided for Unit 1 only. This is referred to as the "stand alone" (SA) case, and all tables showing those costs are identified with that suffix. In the other case, it was assumed that the retrofit of hypothetically-applied SCR systems was being done for both Unit 1 and Unit 2, and there are some components that could be shared between the two units. This is referred to as the "shared facilities" (SF) case, and all tables showing those costs are identified with that suffix.

---

[16] Ibid Reference number 4, June 2005, Excel Spreadsheet OAR-2002-0076-0446, page 390.

Per the EPA's NSR Manual, a BACT analysis is done on a "case-by-case basis"[17]. The "stand alone" estimated total project capital costs for the hypothetical application of SCR alternatives reflect the economic impacts incurred as a result of implementing such technologies on each individual unit at MRYS independent of what may be determined or assumed for other units at this facility or similar units at other facilities. The "shared facilities" estimated total project capital costs for the hypothetical application of SCR alternatives do not account for all economic impacts borne strictly by the unit subject to the analysis, and, as such, are subsidized by the unit(s) involved with the shared facilities. In this "shared facilities" approach, a BACT would be performed more in the manner of a "case-within-a-case" instead of on a "case-by-case" basis. Additionally, BACT is not to be applied on a facility basis. Units having different characteristics, (size, etc.) may have different technologies as BACT. Therefore, each unit should be treated as a separate "stand alone" case. Although the authors believe the "stand alone "case is the proper approach to use, information for both cases has been provided.

TABLE 4-3SA – Unit Capital Cost Factors of NO_X Control Alternatives for MRY Station Unit 1 - Stand Alone SCR Projects

Alt. Label(1)	**NO_X Control Alternative**	**Range(2) (\$/kW)**	**Single Point Unit Capital Cost Factor(3), (\$/kW) MRYS Unit 1**
T2	Hypothetical Tail End SCR w/ ASOFA – Scenario A(4)	(4)	867(4),(5)

infeasibility for installation of the SCR equipment on this boiler are solvable. SCR technology is considered technically infeasible by Minnkota for application at MRYS per the October 2006 NOx BACT Analysis Study report and subsequent submittals in response to comments by the NDDH, EPA, DOJ, and other parties, so this information for the hypothetical application of SCR alternatives is included for comparative purposes only. See Section 4.2.1.2.1 for details of Scenario A and Scenario B that assume replacement of SCR catalyst after a specified number of hours of unit operation. Due to the site-specific nature of factors influencing cost, no comparable cost data ranges for these technologies exist in the literature. A cost range for conventional high-dust SCR technology published in the 2005 EPA Report "Multipollutant Emission Control Technology Options for Coal-fired Power Plants", EPA-600/R-05/034[18] was $55 to $150/kW. Single point unit capital cost factors were derived from Burns & McDonnell internal database and cost estimates prepared specifically for MRYS Unit 1 in 2018 dollars converted to 2006$ as described in the text.

(5) - The single point unit capital cost factor shown for the "advanced" version of SOFA derived from Burns & McDonnell internal database and cost estimate for North Dakota lignite-fired cyclone boilers.

(6) - Estimated capital cost for SNCR point estimate and FLGR point estimate derived from December 2004 budgetary proposal by Fuel Tech. The unit capital cost factor range for FLGR applications on boilers without an existing a high-pressure natural gas supply was not found in available technical literature. See Appendix C2 of the October 2006 NO_X BACT Analysis Study report for details[19].

(7) - NESCAUM 2005 Technical Paper[20]; reburn alternatives on page 2-22, overfire air on page 2-23; posted at their website. See technical references in Appendix A1 of the October 2006 NO_X BACT Analysis Study report for details.

(8) - The single point unit capital cost factor shown for a conventional or fuel-lean gas reburn system includes the estimated capital cost to install a high-pressure natural gas supply pipeline (31.4 $/kW or 15.7 $/kW, respectively), and that both MRYS boilers share the capital cost in proportion to their respective rated MW gross output capacities.

(9) - The single point unit capital cost factor shown for a lignite reburn system is highly site-specific, and assumes that new pulverizers and building enclosures are required. The general cost range for pulverized coal-fired boilers is included in the NESCAUM 2005 Technical Paper; for cyclone boilers is included in the 2005 WRAP Draft Report[21], posted at their website. The single point unit capital cost factor for this alternative for increased PM collection capacity included in lignite reburn option is 91.7 $/kW. See technical references in Appendix A1 of the October 2006 BACT Analysis report for details.

TABLE 4-3SF – Unit Capital Cost Factors of NO_X Control Alternatives for MRY Station Unit 1 – Shared Facilities SCR Projects

Alt. Label(1)	NO_X Control Alternative	Range(2) ($/kW)	Single Point Unit Capital Cost Factor(3), ($/kW) MRYS Unit 1

(8) - The single point unit capital cost factor shown for a conventional or fuel-lean gas reburn system includes the estimated capital cost to install a high-pressure natural gas supply pipeline (31.4 $/kW or 15.7 $/kW, respectively), and that both MRYS boilers share the capital cost in proportion to their respective rated MW gross output capacities.

(9) - The single point unit capital cost factor shown for a lignite reburn system is highly site-specific, and assumes that new pulverizers and building enclosures are required. The general cost range for pulverized coal-fired boilers is included in the NESCAUM 2005 Technical Paper; for cyclone boilers is included in the 2005 WRAP Draft Report[25], posted at their website. The single point unit capital cost factor for this alternative for increased PM collection capacity included in lignite reburn option is 91.7 $/kW. See technical references in Appendix A1 of the October 2006 BACT Analysis report for details.

4.2.1.1.1 CAPITAL COST ESTIMATES FOR HYPOTHETICAL APPLICATION OF SCR NO_X CONTROL ALTERNATIVES

There is no available information on recently-completed similar tail-end or low-dust SCR projects on coal-fired powerplants in the United States that could be used, with adjustments, to properly represent total installed costs that could be expected for MRYS Unit 1. Site-specific needs and challenges identified for applying tail end and low-dust SCR technologies to Milton R. Young Station Unit 1 significantly influence the capital cost estimate for variations of these hypothetically-applied SCR alternatives. Furthermore, the "EPA Air Pollution Control Cost Manual" is not applicable for use in estimating control equipment costs for these hypothetical applications of SCR technology cases, as the EPA Control Cost Manual states:

---

[22] See Reference number 6, March 2005, page 3-63.

[23] See Reference number 3, October 2006, pages C2-3 and C2-7.

[24] See Reference number 7, March 2005.

[25] See Reference number 8, April 2005, page 3-9.

> "The costs for the tail-end arrangement, however, cannot be estimated from this report because they are significantly higher than the high-dust SCR systems due to flue gas reheating requirements."[26]

This requirement for flue gas reheating also applies to the hypothetical applications of low-dust SCR technology to MRYS, due to the cold-side arrangement (downstream of the electrostatic precipitator) instead of a hot-side ESP assumed in the EPA Control Cost Manual. Therefore, the equations in the EPA Control Cost Manual cannot be used for estimating either of the hypothetical application of SCR configurations for which NDDH has requested economic analyses. Thus it was necessary to prepare independent site-specific cost estimates.

The installed capital costs for hypothetical application of tail end and low-dust SCR alternatives were estimated by Burns & McDonnell with inputs from an SCR system supplier with recent design experience involving these SCR configurations, equipment suppliers, and catalyst suppliers with significant European project experience in such technology. Both hypothetically-applied low-dust and tail end SCR designs for MRYS Unit 1 assume one reactor / gas reheat system installed, connecting to the new wet lime flue gas desulfurization absorber currently being constructed. Each hypothetically-applied SCR alternative includes flue gas reheat equipment that is typical for these applications but not required for conventional high-dust/hot side SCR systems. The estimated flue gas volume at a gross boiler heat input and oxygen content corresponding to unit gross nameplate output capacity determined the size of the hypothetically-applied single SCR reactor for these cases. Structures, foundations, ductwork, balance of plant equipment and materials were quantified and included with the hypothetically-applied SCR equipment, which were factored for installation costs. Escalation of project costs, including equipment, materials, engineering and labor costs, is included, along with interest during construction, due to the expected project execution duration being significantly longer than for the other alternatives. Price and scope contingencies were included to account for the uncertainties that the current preliminary design scope and pricing fully reflects what would be necessary to complete implementation of these hypothetically-applied alternatives. Total project costs were considered to be a future value from a financial perspective, which were returned to a 2009 calendar year basis using a present value factor at the 2.5% per year annual discount rate previously assumed in the 2006 NO_X BACT Analysis Study report. A ratio of regional construction cost indices for public utility construction costs between 2006 and 2009 was used to adjust the 2009 total estimated project costs to a 2006 calendar year basis for each of the hypothetically-applied SCR alternatives.

---

[26] See Reference number 10, Section 4.2, Chapter 2, page 2-41, October 2000.

The estimated installed and levelized annual capital costs for the hypothetically-applied SCR systems and previously-analyzed highest-performing form of the various feasible NO_X emission reduction technologies evaluated for cost-effectiveness are shown in Table 4-4SA and Table 4-4SF. These technologies are listed in order of control effectiveness, with the highest ranked option at the top.

TABLE 4-4SA – Estimated Capital Costs for NO_X Control Alternatives - MRY Station Unit 1 - Stand Alone SCR Projects

(1) - Alternative label has been assigned from highest to lowest unit NOx emission rate.

(2) - Installed capital cost is estimated for determination of total capital cost for a particular technology or combination, assuming 257 MWg unit capacity rating. All cost figures in 2006 dollars. See Table 4-5SA for presentation of installed capital costs determined for hypothetical application of SCR alternatives.

(3) - Annualized capital cost = Installed capital cost x 0.08718 annualized capital cost factor.

(4) - The inclusion of tail end and low-dust SCR technologies in this table does not constitute agreement that it is technically feasible to install these technologies on Unit 1 at Milton R. Young Station. The installed capital cost shown for a hypothetically-applied SCR system is based on assumptions that known or expected reasons for technical infeasibility for installation of the SCR equipment on this boiler are solvable. Costs are derived from Burns & McDonnell internal database and cost estimates prepared specifically for MRYS Unit 1 in 2018 dollars converted to 2006$ as described in the text. SCR technology is considered technically infeasible by Minnkota for application at MRYS per the October 2006 NO_X BACT Analysis Study report and subsequent submittals in response to comments by the NDDH, EPA, DOJ, and other parties, so this information for the hypothetical application of SCR alternatives is included for comparative purposes only. See Section 4.2.1.2.1 for details of Scenario A and Scenario B that assumes replacement of SCR catalyst after a specified number of hours of unit operation.

(5) - Costs for gas reburn options include high-pressure natural gas supply pipeline installed capital cost of $8,075,000 for CGR and $4,038,000 for FLGR; and annualized capital cost of $704,000/yr for CGR and $352,000 for FLGR. See footnote number 8 under Table 4-3SA.

(6) - Costs for increased PM collection capacity included in lignite reburn option are $23,561,000 for installed capital cost, and $2,054,000/yr annualized capital cost.

(5) - Costs for gas reburn options include high-pressure natural gas supply pipeline installed capital cost of $8,075,000 for CGR and $4,038,000 for FLGR; and annualized capital cost of $704,000/yr for CGR and $352,000 for FLGR. See footnote number 8 under Table 4-3SF.

(6) - Costs for increased PM collection capacity included in lignite reburn option are $23,561,000 for installed capital cost, and $2,054,000/yr annualized capital cost.

The Total Project Costs estimated for tail end and low-dust SCR technologies hypothetically applied to MRYS Unit 1 are shown in Table 4-5SA and Table 4-5SF in 2018, 2009, and 2006 dollars.

The estimated installed capital costs for the hypothetical application of tail end or low-dust SCR system retrofits on MRYS Unit 1 included the following equipment and components:

- One SCR reactor utilizing a “3 +1” arrangement of catalyst layers, in which three layers of catalyst are initially installed, and space for installation of a fourth layer is provided.
- Sootblowers for each catalyst layer to maintain cleanliness of catalyst
- Flue gas reheat equipment that is typical for these applications but not required for conventional high-dust/hot side SCRs. This reheat equipment includes rotary regenerative heat exchangers (gas-to-gas heaters [GGH]) and natural gas-fired duct burners.
- Underground high-pressure natural gas supply pipeline and pressure regulators and metering equipment
- Hot air recirculation and heating equipment to maintain catalyst in a warm and dry condition during standby periods
- Induced draft booster fan and dampers
- Interconnecting ductwork
- SCR bypass duct and dampers (used during times the boiler is off-line)
- Storage tanks, building, and equipment for unloading and preparation of liquid urea solution
- Circulation pumps and piping for urea solution
- Urea-to-ammonia thermal conversion with urea conversion, metering, atomization, and injection equipment
- Ammonia gas dilution/combustion air fans and burners for natural gas-firing to decompose the urea solution to ammonia
- Service and sootblowing air compressors with dryers
- Electrical motor control centers
- Controls and instrumentation
- Reinforced concrete foundations
- Active coal yard storage modifications to regain lost live capacity and handling equipment due to space consumed by the SCR reactor structures
- Installation labor, materials, and management.

Addition of new electrical loads to the existing plant facilities will be required for the reagent system and new induced draft booster fan power consumption. Based on recent plant electrical distribution equipment installations, additional plant auxiliary electrical power will be available for powering the new hypothetically-applied SCR equipment. Confirmation of these concepts and cost estimates prior to any subsequent plans for implementation requires successful completion of extensive pilot-scale slipstream

testing, and more detailed plant layout and equipment design than has been performed as part of this supplemental update to the October 2006 NO_X BACT Analysis Study report.

The capital cost estimated individually for an ASOFA system retrofit on MRYS Unit 1 as previously described in the initial NO_X BACT Analysis Study report was simply arithmetically added to the hypothetical application of SCR alternatives' capital cost estimates.

4.2.1.2 O&M COST ESTIMATES FOR NO_X CONTROL ALTERNATIVES

Operational costs to implement the hypothetical application of SCR alternatives and previously-analyzed feasible NO_X control alternatives for Milton R. Young Unit 1 were estimated using preliminary conceptual designs and budgetary vendor quotes in place of, or to adjust, the OAQPS cost factors established in the EPA's Air Pollution Control Cost Manual (OAQPS) for SNCR[27] and SCR[28], and using other costs published in technical papers discussing those control technologies. Maintenance costs were estimated as

---

[27] See Reference number 9, October 2000.

[28] See Reference number 10, October 2000.

percentages of installed capital costs, with additional catalyst replacement costs using budgetary vendor quotes based on preliminary conceptual designs and expected design life.

Fixed and variable operating and maintenance costs considered and included in each NO_X control technology's annual O&M costs are estimates of:

- Auxiliary electrical power consumption (megawatt-hours) and incremental purchased power unit costs for operating the additional control equipment;
- Natural gas consumption and unit cost for hypothetical application of SCR alternatives' flue gas reheating and urea-to-ammonia thermal conversion systems and feasible fuel reburn alternatives;
- Reagent consumption and reagent unit cost for hypothetical application of SCR alternatives and feasible SNCR alternatives;
- Reagent dilution water consumption and unit cost for SNCR alternatives.
- Catalyst removal and replacement for hypothetical application of SCR alternatives.
- Increases or savings in auxiliary electrical power consumption for changes in coal preparation equipment and loading, primarily for fuel reburn cases;
- General operating labor, plus maintenance labor and materials devoted to the additional emission control equipment and its impact on existing boiler and plant equipment;
- Costs for purchase of replacement electrical power expected to result from loss of unit availability, i.e., outages attributable to the control option which reduce annual net electrical generation available for distribution.

For economic evaluation purposes, a 12-month rolling average running plant capacity factor of 96.6 percent (based on a historic (demonstrated) sustainable unit output capacity of 253 MW_g) combined with a 12-month rolling average availability (uptime) of 8,528 operating hours (97.3 percent of 8760 hours per year) resulting in an equivalent annual average unit capacity factor of 94.1% was assumed for Unit 1's pre-control baseline annual operation. A 12-month rolling average heat input rate of 2,744 mmBtu/hr and a 12-month rolling average NO_X emission rate of 0.849 lb/mmBtu from pre-control maximum rolling 12 month summation of nitrogen oxides mass emissions were assumed for calculating equivalent annual average control and cost-effectiveness for MRY Station Unit 1.

Tables 4-6SA and 4-6SF show the estimated annual operating and maintenance costs and levelized annual O&M cost values for the hypothetically-applied SCR alternative cases and the highest-performing form of previously-evaluated feasible NO_X emission reduction technologies. These are listed in order of control effectiveness, with the highest ranked options at the top. The cost methodology summarized in Appendix C3 of the 2006 NO_X BACT Analysis Study report provides more details for the levelized annual O&M cost calculations and cost factors for the previously-analyzed feasible NO_X control alternatives[29].

TABLE 4-6SA – Estimated O&M Costs for NO_X Control Alternatives - MRY Station Unit 1 - Stand Alone SCR Projects

Alt. Label(1)	**NOx Control Alternative**	**Annual O&M Cost(2) $1,000**	**Levelized Annual O&M Cost(2),(3) $1,000**
T2	Hypothetical Tail End SCR w/ ASOFA – Scenario A(4)	20,048	25,034
T1	Hypothetical Tail End SCR w/ ASOFA – Scenario B(4)	29,361	36,664

4.2.1.2.1 O&M COST ESTIMATES FOR HYPOTHETICAL APPLICATION OF SCR NO_X CONTROL ALTERNATIVES

The hypothetical application of tail-end and low-dust SCR w/ ASOFA alternatives will involve significantly higher operating costs compared with the existing operation of MRYS Unit 1. The system uses an amine reagent in the form of concentrated aqueous urea solution, which is thermally converted to gaseous ammonia, carbon dioxide, and water vapor. The estimated unit cost of this urea was assumed to average $379/ton (delivered to the plant site via truck-tanker trailers; unit pricing based on 50% concentration as established for the 2006 NO_X BACT Analysis Study report). Consumption of urea converted to ammonia reagent was based upon recent equipment vendor budgetary proposals and SCR consultant inputs.

For the hypothetically-applied SCR cases, using the existing induced draft fans is not expected to significantly change the overall fan horsepower demand on those fans' electric motors. There will be new plant electrical power demand due to a new induced draft booster fan required to overcome the estimated additional flue gas pressure drop resulting from reactor, ductwork, and gas-to-gas heat exchanger equipment assumed for the hypothetically-applied SCR systems. The additional auxiliary electric power demand for the hypothetically-applied tail end SCR systems was calculated to be 9.7 MW, using estimated annual average electrical loads of the booster fan, direct flue gas reheat burner combustion air fan, urea-to-ammonia conversion dilution/combustion air fan, and SCR sootblower and service air compressor equipment based on preliminary equipment vendor budgetary proposals developed from Burns & McDonnell ductwork sizing and designs. Estimated annual average electrical power demands for hypothetically-applied low-dust SCR systems were calculated to be 8.0 MW. Replacement of electrical power resulting from these reductions in net unit electrical output was included as a cost, assuming $35 per megawatt-hour.

Hypothetically-applied tail end and low-dust SCR equipment requiring annual maintenance includes booster fan, gas-to-gas heat exchangers, flue gas reheat duct burners, and compressor equipment. This general annual maintenance cost was estimated as 3 percent of installed capital costs.

To account for the possible range of O & M costs due to catalyst replacement, two variations (Scenario A and Scenario B) were applied. These two scenarios were used for both hypothetical applications of tail-end and low-dust SCR technology alternatives. Each scenario was based on scheduled additions and/or replacement of the exposed catalyst after a certain number of hours of operation, repeated throughout the 20 year operating span considered in the analysis. The installed unit cost of replacement catalyst assumed for the hypothetical application of full-time tail end or low-dust SCR alternatives is $7,500 per cubic meter in 2006 dollars. The basis for development of the two scenarios is described below.

During preparation of the cost estimate, Burns & McDonnell consulted with two SCR catalyst vendors experienced with biomass-fired boiler SCRs and European coal-fired boilers with low-dust and tail end SCR systems. However, neither of these vendors was willing to guarantee a catalyst replacement schedule for cyclone boilers firing North Dakota lignite without results following successful extensive pilot-scale slipstream testing that confirm the deactivation and fouling rates. According to these catalyst suppliers, there is no SCR operating experience in the world found to be directly comparable to the hypothetically-applied tail end and low-dust SCR cases on North Dakota lignite-fired cyclone boilers being evaluated. Thus they were unable to offer a guaranteed catalyst replacement schedule based on their experience.

Based on information obtained in discussions with the catalyst vendors, the longest catalyst replacement schedule they would both agree upon as an estimated (not guaranteed) value was 16,000 hours. Both vendors indicated that actual experience could result in a shorter replacement cycle, and that the actual guarantee value could not be developed until extensive pilot slipstream testing had been completed. This led Burns & McDonnell to develop two hypothetically-applied SCR catalyst replacement scenarios to bracket possible outcomes.

Scenario A assumed a hypothetically-applied catalyst replacement schedule of 16,000 hours. Specifically for MRYS Unit 1, this scenario is based on the replacement of one catalyst layer every 16,000 operating hours (essentially every two years of operation).

Scenario B assumed that the fouling of the catalyst would be severe, and that it would be necessary for Minnkota to perform catalyst maintenance at each scheduled boiler cleaning outage. The current schedule of boiler cleaning outages on Unit 1 is three times per year. Therefore, Scenario B for Unit 1 is based on the replacement of one catalyst layer at each boiler cleaning outage. This means that each catalyst layer in the four layer SCR reactor is exposed to flue gas during approximately 16 months of operation and then is replaced. By assuming that catalyst management activities would coincide with scheduled boiler cleaning outages, Scenario B provides some minimization of the impact of catalyst replacement on unit operation.

As noted above, it is not known what the actual frequency of catalyst replacement would need to be for a hypothetically-applied tail-end or low dust SCR system operating on a cyclone-fired boiler burning North Dakota lignite, but the two scenarios described above are the catalyst replacement numbers assumed for this comparative economic analysis.

SCR catalyst replacements are additive to the general annual hypothetically-applied low-dust and tail end SCR equipment maintenance. Catalyst replacement costs are based on catalyst vendor quotation of volume of catalyst, estimated to be three layers initially (top, middle-upper and middle-lower) at 146 cubic meters per layer per reactor for the single reactor. A fourth (bottom) layer at 195 cubic meters is expected to be required after initial operation of hypothetically-applied full-time tail end or low-dust SCR alternatives, as part of the catalyst replacement program. Catalyst replacement costs for the hypothetical application of SCR alternatives were estimated for the two different catalyst management scenarios described above.

Annual unit operating time will be reduced as a result of the expected outages and maintenance of the hypothetically-applied SCR equipment, including catalyst cleaning and management practices. Additional outage time of 213 hours per year was estimated to be attributable to the hypothetical application of tail end SCR Scenario A alternative (assuming 16,000 hour catalyst life), and 938 hours per year for Scenario B TESCR case (assuming three layers are replaced every year) over and above the hours per year of outage time assumed for ASOFA impacts. Additional outage time of 256 hours per year was estimated to be attributable to the hypothetical application of low-dust SCR Scenario A alternative, and 981 hours per year for the Scenario B LDSCR case over and above outage time assumed for ASOFA impacts. The expected loss of electrical power generation from these reductions in net output was included as a cost, assuming $35 per megawatt-hour for replacement power.

Table C.4-1 provides the estimated unit availability and corresponding operating time and outage time due to the four hypothetically-applied SCR technology cases, along with the ASOFA and baseline numbers from the referenced Appendix C3 of the initial NO_X BACT Analysis Study report[30].

TABLE C.4-1 – Expected Availability Reductions for MRYS Unit 1 NO_X Controls

Alt.[1]	NOx Control Alternative	Estimated Annual Average Unit Operating Time			
		Unit Availability[2]	Unit Operating Time[3], hrs/yr	Unit Outage Time[4], hrs/yr	Unit Operating Time Reduction[5], hrs/yr
T2	Hypothetical Tail End SCR w/ ASOFA – Scenario A(6)	0.928	8127	633	401
T1	Hypothetical Tail End SCR w/ ASOFA – Scenario B(6)	0.845	7402	1358	1126
L2	Hypothetical Low-Dust SCR w/ ASOFA – Scenario A(6)	0.923	8084	676	444
L1	Hypothetical Low-Dust SCR w/ ASOFA – Scenario B(6)	0.840	7359	1401	1169
E	SNCR w/ ASOFA	0.942	8255	505	273
D	Gas Reburn w/ ASOFA	0.952	8340	420	188
C	Coal Reburn w/ ASOFA	0.937	8212	548	316
B	FLGR w/ ASOFA	0.952	8340	420	188
A	Advanced SOFA (ASOFA)	0.952	8340	420	188
	Baseline	0.973	8528	232	0

(1) – Alternative number has been previously assigned from least removal to highest removal percentage.
(2) – 12-month baseline availability is assumed at 97.3 percent. These values reflect estimated amounts of negative reliability impact expected from the implementation of the individual NOx control technology.
(3) – Annual operating time is annual average availability multiplied by 8760 hrs/yr of possible uptime.
(4) – Annual outage time is 8760 hrs/yr possible operating time minus estimated annual operating time.
(5) – Annual operating time reduction resulting from the implementation of the individual NOx control technique is the difference between the baseline and expected annual outage times.
(6) – The inclusion of tail-end and low-dust SCR technologies in this table does not constitute agreement that it is technically feasible to install these technologies on Unit 1 at Milton R. Young Station. The estimated annual unit availability factors shown for hypothetically-applied SCR systems are based on assumptions that known or expected reasons for technical infeasibility for installation and operation and maintenance of the SCR equipment on this boiler are solvable. SCR technology is considered technically infeasible by Minnkota for application at MRYS per the October 2006 NO_X BACT Analysis Study report and subsequent submittals in response to comments by the NDDH, EPA, DOJ, and other parties, so this information for the hypothetical application of SCR alternatives is included for comparative purposes only. See Section 4.2.1.2.1 for details of Scenario A and Scenario B that assumes replacement of SCR catalyst after a specified number of hours of unit operation.

Table C.4-2 includes estimated equivalent average annual unit running plant capacity ratios and unit generation reductions due to the four hypothetically-applied SCR cases, along with the ASOFA and baseline numbers from the referenced Appendix C3 of the initial NO_X BACT Analysis Study report[31]. These numbers assume the reduction in annual plant output is a combination of a reduction of annual operating time and capacity reductions associated with the control alternatives.

---

[31] Ibid Reference number 3, October 2006, pages C3-1 through C3-12.

TABLE C.4-2 – Expected Capacity Reductions for MRYS Unit 1 NO_X Controls

Alt. Label[1]	NOx Control Alternative	Estimated Annual Average Unit Electrical Power Generation Reduction from Operating Time Reduction		
		Unit Running Plant Capacity Ratio[2]	Unit Generation Reduction[3] kW-hrs/yr	Unit Generation Reduction Cost[4], 1000$/yr
T2	Hypothetical Tail End SCR w/ ASOFA – Scenario A[5]	0.937	97,976,764	3,429
T1	Hypothetical Tail End SCR w/ ASOFA – Scenario B[5]	0.937	275,168,784	9,631
L2	Hypothetical Low-Dust SCR w/ ASOFA – Scenario A[5]	0.942	108,399,824	3,794
L1	Hypothetical Low-Dust SCR w/ ASOFA – Scenario B[5]	0.942	285,591,844	9,996[6]
E	SNCR w/ ASOFA	0.965	67,660,606	2,368
D	Gas Reburn w/ ASOFA	0.957	46,120,681	1,614
C	Lignite Reburn w/ ASOFA	0.961	77,958,350	2,729
B	FLGR w/ ASOFA	0.962	46,400,200	1,624
A	Advanced SOFA (ASOFA)	0.966	46,586,546	1,631
	Baseline	0.966	0	0

(1) - Alternative designation has been previously assigned from least removal to highest removal percentage.
(2) - 12-month baseline running plant capacity ratio is assumed at 96.6 percent (= 244.4/253.0). These values reflect estimated amounts of negative annual output capacity impact expected from the implementation of the individual NOx control technique. Used only for calculation of annual power usage in Table C.4-3.
(3) - Annual electricity generation reduction is annual unit operating time reduction multiplied by the 12-month average gross output of 244.4 MW.
(4) - Annual electricity generation reduction cost is the annual electricity generation reduction (kW-hrs/yr) resulting from the implementation of the individual NOx control technique multiplied by the incremental value of electricity generation, assumed to be $35.00/MW-hr. All cost figures in 2006 dollars.
(5) - The inclusion of tail-end and low-dust SCR technologies in this table does not constitute agreement that it is technically feasible to install these technologies on Unit 1 at Milton R. Young Station. The estimated annual unit running plant capacity factors shown for hypothetically-applied SCR systems are based on assumptions that known or expected reasons for technical infeasibility for installation and operation and maintenance of the SCR equipment on this boiler are solvable. SCR technology is considered technically infeasible by Minnkota for application at MRYS per the October 2006 NO_X BACT Analysis Study report and subsequent submittals in response to comments by the NDDH, EPA, DOJ, and other parties, so this information for the hypothetical application of SCR alternatives is included for comparative purposes only. See Section 4.2.1.2.1 for details of Scenario A and Scenario B that assumes replacement of SCR catalyst after a specified number of hours of unit operation.
(6) Unit Generation Reduction for low-dust SCR Scenario B was $11,940,000. It should be shown as $9,996,000 instead. This does not affect economics shown in subsequent tables and graphs. Revised February, 2010.

Table C.4-3 includes estimated unit gross and net electrical power demands (kilowatts) and annual usage (kW-hrs per year) used to calculate unit generation reductions and replacement electrical power costs due to the four hypothetically-applied SCR cases, along with the ASOFA numbers from the referenced Appendix

C3 of the initial NO_X BACT Analysis Study report[32]. These numbers assume that the reductions of annual operating time and capacity associated with the control alternatives are also applied.

TABLE C.4-3 – Expected Auxiliary Electrical Power Demand Changes for MRYS Unit 1 NO_X Controls

Alt. Label(1)	NOx Control Alternative	Estimated Annual Average APC NOx Equipment Auxiliary Electrical Power Demand and Usage				
		Gross Demand (2) kW	Credit(3) kW	Total Net Demand(4) kW	Power Usage(5) kW-hrs/yr	Power Usage Cost(6), 1000$/yr
T2	Hypothetical Tail End SCR w/ ASOFA – Scenario A(7)	9,685	0	9,685	73,768,605	2,582
T1	Hypothetical Tail End SCR w/ ASOFA – Scenario B(7)	9,685	0	9,685	67,189,753	2,352
L2	Hypothetical Low-Dust SCR w/ ASOFA – Scenario A(7)	8,012	0	8,012	61,018,532	2,136
L1	Hypothetical Low-Dust SCR w/ ASOFA – Scenario B(7)	8,012	0	8,012	55,548,184	1,944
E	SNCR w/ ASOFA	73.1	0	73.1	582,411	20
D	Gas Reburn w/ ASOFA	1	133	(132)	(1,054,343)	(37)
C	Lignite Reburn w/ ASOFA	4,666	261	4,405	11,905,082	1,217
B	FLGR w/ ASOFA	1	73	(72)	(578,744)	(20)
A	Advanced SOFA (ASOFA)	1	0	1	8,058	0.3

(1) - Alternative designation has been previously assigned from least removal to highest removal percentage.
(2) - The APC NOx equipment gross auxiliary electrical power demand of alternatives is the sum of the demand for individual technologies combined by simple addition. Actual power demands may differ from this due to positive or negative synergistic effects. Coal reburn includes 1,507 kW for feed preparation and conveying equipment demand plus 3,158 kW for the COHPAC system addition for PM control.
(3) - The APC NOx equipment auxiliary electrical power demand credit of coal reburn alternatives is the estimated result of lower cyclone coal preparation and feeder power demand due to lower boiler cyclone coal equipment loading. Actual power demands may differ from this due to accuracy of estimates for assumed amount of operating horsepower reduction.
(4) - The total net auxiliary electrical power demand is the sum of the gross demand and credit.
(5) - The annual change in APC NOx equipment auxiliary electrical power demand electricity usage in kW-hrs/yr for these alternatives is the net power demand multiplied by the estimated annual operating time and running plant capacity ratio which reflects the adjustment for any expected availability and capacity impacts from the implementation of the control technique.
(6) - The annual change in APC NOx equipment auxiliary electrical power demand electricity cost is the annual change in kW-hrs/yr for these alternatives resulting from the implementation of the individual NOx control technique multiplied by the incremental value of electricity generation, assumed to be $35.00/MW-hr. All cost figures in 2006 dollars.
(7) - The inclusion of tail-end and low-dust SCR technologies in this table does not constitute agreement that it is technically feasible to install these technologies on Unit 1 at Milton R. Young Station. The estimated power demands shown for hypothetically-applied SCR systems are based on Burns & McDonnell estimates developed from preliminary equipment and ductwork sizing and designs with vendor budgetary proposals. SCR technology is considered technically infeasible by Minnkota for application at MRYS per the October 2006 NO_X BACT Analysis Study report and subsequent submittals in response to comments by the NDDH, EPA, DOJ, and other parties, so this information for the hypothetical application of SCR alternatives is included for comparative purposes only. See Section 4.2.1.2.1 for details of Scenario A and Scenario B that assumes replacement of SCR catalyst after a specified number of hours of unit operation.

---

[32] Ibid Reference number 3, October 2006, pages C3-1 through C3-11.

Table C.4-4 includes estimated net unit electrical annual power usage (kW-hrs per year) and expected reductions in annual operating time to calculate unit generation reductions due to the four hypothetically-applied SCR cases, along with the ASOFA numbers from the referenced Appendix C3 of the initial NO_X BACT Analysis Study report[33]. These numbers assume the reduction in annual plant output is a combination of a reduction of net unit generation because of electrical power usage and reductions in annual operating time and capacity associated with the control alternatives.

TABLE C.4-4 – Expected Auxiliary Electrical Power Demand and Generation Reduction Cost Changes for MRY Unit 1 NO_X Controls

		Estimated Annual Change in Unit Generation Due to APC NOx Equipment Auxiliary Power Electricity Demand and Generation Reduction			
Alt. Label(1)	**NOx Control Alternative**	**APC Electrical Power Usage(2) kW-hrs/yr**	**Unit Generation Reduction(3) kW-hrs/yr**	**Total Unit Electrical Power Generation Change(4) kW-hrs/yr**	**Total Unit Electrical Power Generation Change Cost(5) 1000$/yr**
T2	Hypothetical Tail End SCR w/ ASOFA – Scenario A(6)	73,768,605	97,976,764	171,745,369	6,011
T1	Hypothetical Tail End SCR w/ ASOFA –Scenario B(6)	67,189,753	275,168,784	342,358,537	11,983
L2	Hypothetical Low-Dust SCR w/ ASOFA – Scenario A(6)	61,018,532	108,399,824	169,418,356	5,930
L1	Hypothetical Low-Dust SCR w/ ASOFA – Scenario B(6)	55,548,184	285,591,844	341,140,028	11,940
E	SNCR w/ ASOFA	582,411	67,660,606	68,243,017	2,389
D	Gas Reburn w/ ASOFA	(1,054,343)	46,120,681	45,066,338	1,577
C	Lignite Reburn w/ ASOFA	11,905,082	77,958,350	89,863,432	3,946
B	FLGR w/ ASOFA	(578,744)	46,400,200	45,821,456	1,604
A	Advanced SOFA (ASOFA)	8,058	46,586,546	46,594,605	1,631

(1) - Alternative designation has been previously assigned from least removal to highest removal percentage.
(2) - The annual change in APC NOx equipment auxiliary electrical power demand electricity usage in kW-hrs/yr for these alternatives is the net power demand multiplied by the estimated annual operating time and running plant capacity ratio which reflects the adjustment for any expected availability and capacity impacts from the implementation of the control technique.
(3) - Annual electricity generation reduction is annual operating time reduction multiplied by the 12-month average gross output of 244.4 MW.
(4) - The total unit electrical power generation change is the sum of the annual change in APC NOx equipment auxiliary electrical power demand electricity usage plus the annual electricity generation reduction resulting from the implementation of the individual NOx control alternative.
(5) - The total unit electrical power generation change cost is the total generation change (kw-hrs/yr) multiplied by the incremental value of electricity generation, assumed to be $35.00/MW-hr. All cost figures in 2006 dollars.
(6) - The inclusion of tail-end and low-dust SCR technologies in this table does not constitute agreement that it is technically feasible to install these technologies on Unit 1 at Milton R. Young Station. The estimated power demand shown for hypothetically-

applied SCR systems are based on Burns & McDonnell estimates developed from preliminary equipment and ductwork sizing and designs with vendor budgetary proposals. SCR technology is considered technically infeasible by Minnkota for application at MRYS per the October 2006 NO_X BACT Analysis Study report and subsequent submittals in response to comments by the NDDH, EPA, DOJ, and other parties, so this information for the hypothetical application of SCR alternatives is included for comparative purposes only. See Section 4.2.1.2.1 for details of Scenario A and Scenario B that assumes replacement of SCR catalyst after a specified number of hours of unit operation.

4.2.1.3 LEVELIZED TOTAL ANNUAL COST ESTIMATES FOR MRY STATION NO_X CONTROLS

A comparison of the control versus cost-effectiveness of four hypothetically-applied SCR cases and previously-analyzed feasible NO_X control alternatives on Milton R. Young Unit 1 was made. This is summarized as shown in Tables 4-7SA and 4-7SF, Figures 4-1SA and 4-1SF, and Figures 4-2SA and 4-2SF for MRY Station Unit 1.

TABLE 4-7SA – Estimated Annual Emissions and Levelized Total Annual Cost for NO_X Control Alternatives - MRY Station Unit 1 - Stand Alone SCR Projects

Alt. Label(1)	NOx Control Alternative	Annual NOx Emissions(2) Tons/yr	Annual NOx Emissions Reduction(3) Tons/yr	Levelized Total Annual Cost(4) $1,000	Average Control Cost(5) $/ton
T2	Hypothetical Tail End SCR w/ ASOFA – Scenario A(6)	589	9,345	44,465	4,758
T1	Hypothetical Tail End SCR w/ ASOFA – Scenario B(6)	536	9,398	56,095	5,969
L2	Hypothetical Low-Dust SCR w/ ASOFA – Scenario A(6)	586	9,348	38,649	4,134
L1	Hypothetical Low-Dust SCR w/ ASOFA – Scenario B(6)	533	9,401	52,193	5,552
E	SNCR w/ ASOFA	4,025	5,909	7,472	1,265
D	Gas Reburn w/ ASOFA	4,275	5,659	37,334(7)	6,597
C	Lignite Reburn w/ ASOFA	4,343	5,591	11,388(8)	2,037
B	FLGR w/ ASOFA	5,260	4,674	16,990(7)	3,635
A	Advanced SOFA (ASOFA)	5,874	4,060	2,489	613
	Baseline	9,934	0	0	

(1) - Alternative label has been assigned from highest to lowest unit NOx emission rate.

(2) - Estimated annual emission tons assume an annual unit uptime availability factor specific to each alternative; 9,934 (= 0.973*8760*2,330/2000) was assumed for the baseline case.

(3) - Estimated annual tons of emission reduction is the difference between annual baseline tons and each alternative's annual emissions (tons).

(4) - Levelized Total Annual Cost = Annualized Installed Capital Cost + Levelized Annual O&M cost. See note 3 from Tables 4-4SA and 4-6SA for annualized cost factors. Emissions are calculated from unit emission rates, control percentage, hourly heat input, and annual hrs/yr operation compared to pre-control baseline emissions based on annual operation at baseline pre-control NOx emission rate. Revised February, 2010.

(5) - Average Control Cost Effectiveness ($/ton) is the Levelized Total Annual Cost ($/yr) divided by Annual Emission Reduction (tons/yr). All cost figures in 2006 dollars. Revised February, 2010.

(6) - The inclusion of tail-end and low-dust SCR technologies in this table does not constitute agreement that it is technically feasible to install these technologies on Unit 1 at Milton R. Young Station. The estimated annual NOx removal and LTAC shown for a hypothetically-applied SCR system is based on assumptions that known or expected reasons for technical infeasibility for installation of the SCR equipment on this boiler are solvable. Costs are derived from Burns & McDonnell internal database and cost estimates specifically for MRYS Unit 1 in 2006 dollars. SCR technology is considered technically infeasible by Minnkota for application at MRYS per the October 2006 NO_X BACT Analysis Study report and subsequent submittals in response to comments by the NDDH, EPA, DOJ, and other parties, so this information for the hypothetical application of SCR alternatives is included for comparative purposes only. See Section 4.2.1.2.1 for details of Scenario A and Scenario B that assumes replacement of SCR catalyst after a specified number of hours of unit operation.

(7) - LTAC for gas reburn options include high-pressure natural gas supply pipeline annualized capital cost of $704,000/yr for CGR and $352,000 for FLGR. See footnote number 8 under Table 4-3SA.

(8) - LTAC for increased PM collection capacity included in lignite reburn option are approximately $2,054,000 for annualized capital cost plus $2,527,000/yr for annualized O&M cost, for a LTAC subtotal of $4,581,000/yr.

TABLE 4-7SF – Estimated Annual Emissions and Levelized Total Annual Cost for NO_X Control Alternatives - MRY Station Unit 1 - Shared Facilities SCR Projects

Alt. Label(1)	NOx Control Alternative	Annual NOx Emissions(2) Tons/yr	Annual NOx Emissions Reduction(3) Tons/yr	Levelized Total Annual Cost(4) $1,000	Average Control Cost(5) $/ton
T2	Hypothetical Tail End SCR w/ ASOFA – Scenario A(6)	589	9,345	39,307	4,206
T1	Hypothetical Tail End SCR w/ ASOFA – Scenario B(6)	536	9,398	50,937	5,420
L2	Hypothetical Low-Dust SCR w/ ASOFA – Scenario A(6)	586	9,348	33,526	3,586
L1	Hypothetical Low-Dust SCR w/ ASOFA – Scenario B(6)	533	9,401	45,244	4,813
E	SNCR w/ ASOFA	4,025	5,909	7,472	1,265
D	Gas Reburn w/ ASOFA	4,275	5,659	37,334(7)	6,597
C	Lignite Reburn w/ ASOFA	4,343	5,591	11,388(8)	2,037
B	FLGR w/ ASOFA	5,260	4,674	16,990(7)	3,635
A	Advanced SOFA (ASOFA)	5,874	4,060	2,489	613
	Baseline	9,934	0	0	

(1) - Alternative label has been assigned from highest to lowest unit NOx emission rate.

(2) - Estimated annual emission tons assume an annual unit uptime availability factor specific to each alternative; 9,934 (= 0.973*8760*2,330/2000) was assumed for the baseline case.

(3) - Estimated annual tons of emission reduction is the difference between annual baseline tons and each alternative’s annual emissions (tons).

(4) - Levelized Total Annual Cost = Annualized Installed Capital Cost + Levelized Annual O&M cost. See note 3 from Tables 4-4SF and 4-6SF for annualized cost factors. Emissions are calculated from unit emission rates, control percentage, hourly heat input, and annual hrs/yr operation compared to pre-control baseline emissions based on annual operation at baseline pre-control NOx emission rate. Revised February, 2010.

(5) - Average Control Cost Effectiveness ($/ton) is the Levelized Total Annual Cost ($/yr) divided by Annual Emission Reduction (tons/yr). All cost figures in 2006 dollars. Revised February, 2010.

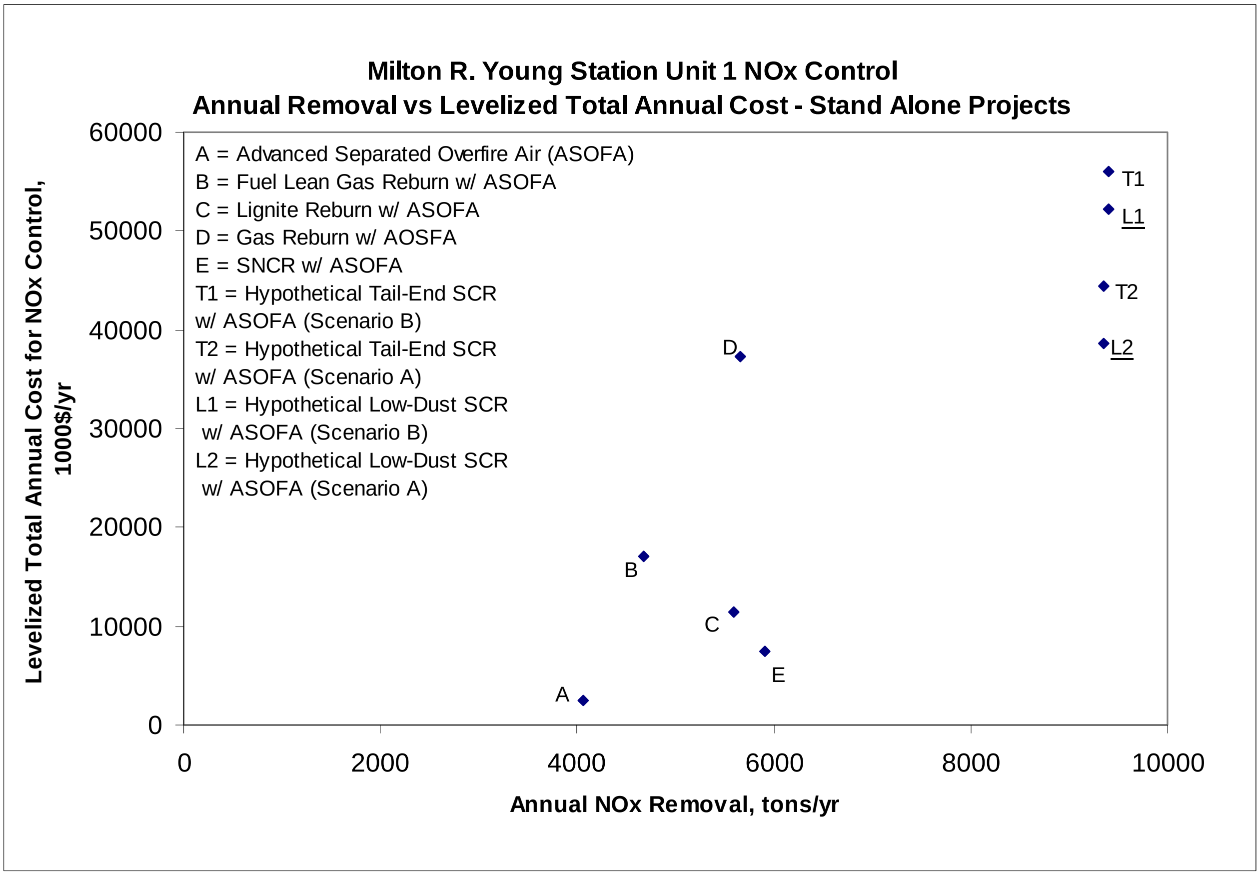
(6) - The inclusion of tail-end and low-dust SCR technologies in this table does not constitute agreement that it is technically feasible to install these technologies on Unit 1 at Milton R. Young Station. The estimated annual NOx removal and LTAC shown for a hypothetically-applied SCR system is based on assumptions that known or expected reasons for

technical infeasibility for installation of the SCR equipment on this boiler are solvable. Costs are derived from Burns & McDonnell internal database and cost estimates specifically for MRYS Unit 1 in 2006 dollars. SCR technology is considered technically infeasible by Minnkota for application at MRYS per the October 2006 NO_X BACT Analysis Study report and subsequent submittals in response to comments by the NDDH, EPA, DOJ, and other parties, so this information for the hypothetical application of SCR alternatives is included for comparative purposes only. See Section 4.2.1.2.1 for details of Scenario A and Scenario B that assumes replacement of SCR catalyst after a specified number of hours of unit operation.

(7) - LTAC for gas reburn options include high-pressure natural gas supply pipeline annualized capital cost of $704,000/yr for CGR and $352,000 for FLGR. See footnote number 8 under Table 4-3SF.

(8) - LTAC for increased PM collection capacity included in lignite reburn option are approximately $2,054,000 for annualized capital cost plus $2,527,000/yr for annualized O&M cost, for a LTAC subtotal of $4,581,000/yr.

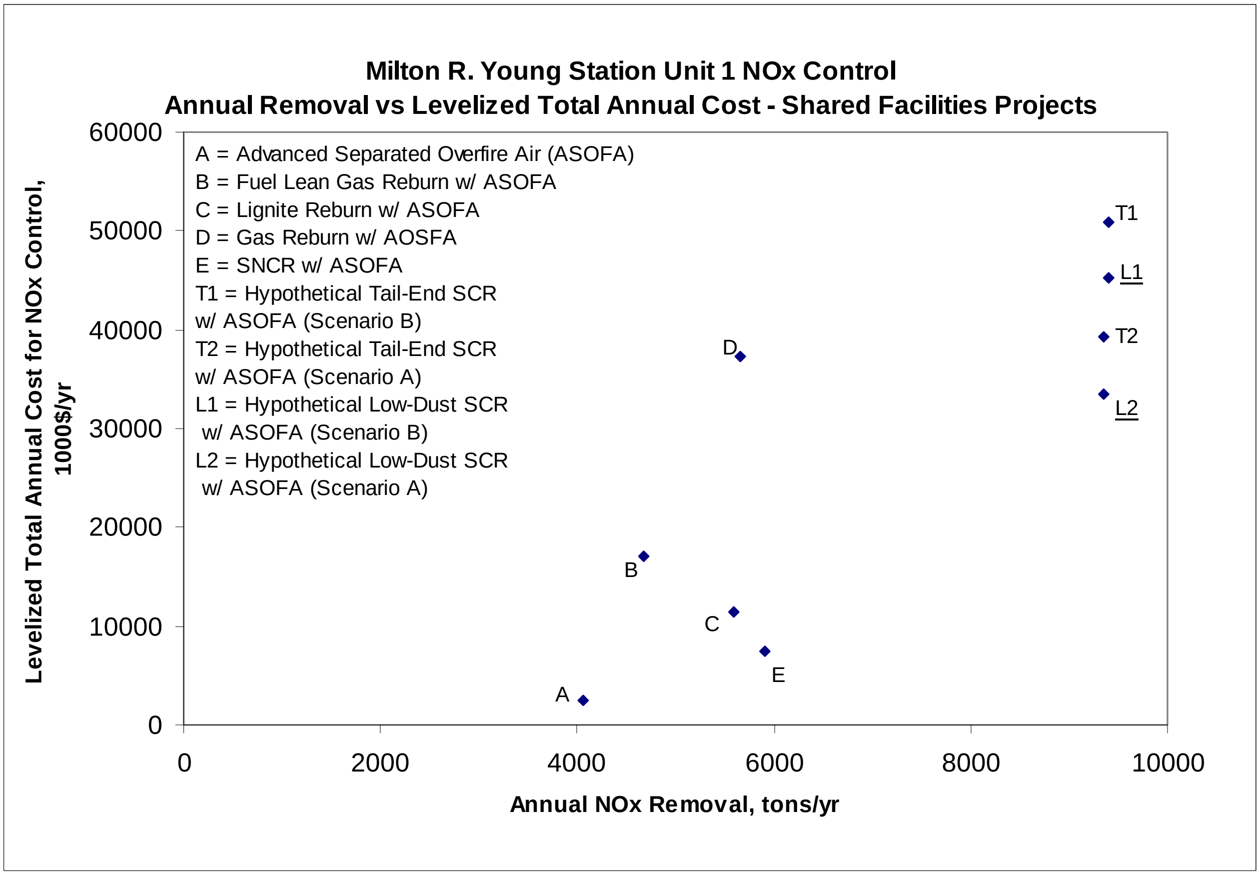
Figure 4-1SA – NO_X Control Cost Effectiveness - MRY Station Unit 1(1)
Stand Alone SCR Projects



(1) - All cost figures in 2006 dollars. Numbers are listed and qualifiers are noted in Table 4-7SA. Revised February, 2010.

(2) - The inclusion of tail-end and low-dust SCR technologies in this figure does not constitute agreement that it is technically feasible to install these technologies on Unit 1 at Milton R. Young Station. The estimated annual NOx removal and LTAC shown for a hypothetically-applied SCR system is based on assumptions that known or expected reasons for technical infeasibility for installation of the SCR equipment on this boiler are solvable. SCR technology is considered technically infeasible by Minnkota for application at MRYS per the October 2006 NO_X BACT Analysis Study report and subsequent submittals in response to comments by the NDDH, EPA, DOJ, and other parties, so this information for the hypothetical application of SCR alternatives is included for comparative purposes only. See Section 4.2.1.2.1 for details of Scenario A and Scenario B that assumes replacement of SCR catalyst after a specified number of hours of unit operation.

Figure 4-1SF – NO_X Control Cost Effectiveness - MRY Station Unit 1(1)
Shared Facilities SCR Projects



(1) - All cost figures in 2006 dollars. Numbers are listed and qualifiers are noted in Table 4-7SF. Revised February, 2010.

(2) - The inclusion of tail-end and low-dust SCR technologies in this figure does not constitute agreement that it is technically feasible to install these technologies on Unit 1 at Milton R. Young Station. The estimated annual NOx removal and LTAC shown for a hypothetically-applied SCR system is based on assumptions that known or expected reasons for technical infeasibility for installation of the SCR equipment on this boiler are solvable. SCR technology is considered technically infeasible by Minnkota for application at MRYS per the October 2006 NO_X BACT Analysis Study report and subsequent submittals in response to comments by the NDDH, EPA, DOJ, and other parties, so this information for the hypothetical application of SCR alternatives is included for comparative purposes only. See Section 4.2.1.2.1 for details of Scenario A and Scenario B that assumes replacement of SCR catalyst after a specified number of hours of unit operation.

The purpose of Figures 4-1SA and 4-1SF is to show the range of control and cost for four hypothetically-applied SCR cases and previously-analyzed feasible NO_X control alternatives on Milton R. Young Unit 1 alternatives evaluated.

Data points for conventional gas reburn (Point D) and fuel-lean gas reburn (Point B) with advanced separated overfire air, and lignite reburn with ASOFA (Point C), in Figures 4-1SA and 4-1SF are inferior and therefore were eliminated from further control cost-effectiveness analysis.

A dominant set of control alternatives was determined by generating what is called the "envelope of least-cost alternatives". The dominant controls cost curve is the best fit line through the points forming the rightmost boundary of the data zone on a scatter plot of the annual NO_X removal tonnage versus LTAC for the various remaining BACT alternatives. Average and incremental annual costs and NO_X emission reductions for the dominant least-cost control alternatives remaining after the elimination of the obviously inferior options are listed in Tables 4-8SA and 4-8SF.

TABLE 4-8SA – Dominant Controls Cost Curve Points for NO_X Control Alternatives - MRY Station Unit 1 - Stand Alone SCR Projects

Alt. Label(1)	**NOx Control Alternative**	**Levelized Total Annual Cost(2),(3) ($1,000/yr)**	**Annual Emission Reduction(3) (tpy)**	**Incremental Levelized Total Annual Cost(2),(4) ($1,000/yr)**	**Incremental Annual Emission Reduction(4) (tpy)**	**Incremental Control Cost Effectiveness ($/ton)(2),(4)**
T2	Hypothetical Tail End SCR w/ ASOFA – Scenario A(5)	44,465	9,345	36,993	3,437	10,765
T1	Hypothetical Tail End SCR w/ ASOFA – Scenario B(5)	56,095	9,398	48,623	3,489	13,936
L2	Hypothetical Low-Dust SCR w/ ASOFA – Scenario A(5)	38,649	9,348	31,777	3,440	9,064
L1	Hypothetical Low-Dust SCR w/ ASOFA – Scenario B(5)	52,193	9,401	44,721	3,492	12,806
E	SNCR w/ ASOFA	7,472	5,909	4,982	1,849	2,694
A	Advanced SOFA (ASOFA)	2,489	4,060	2,489	4,060	613

(1) - Alternative label has been assigned from highest to lowest unit NOx emission rate. Dominant controls cost curve points from lowest (ASOFA) to highest (TESCR w/ ASOFA – 16,000 hrs) are labeled the same as in Table 4-7SA, and on the graphs that accompany this table (Points B, C, and D were eliminated).

(2) - All cost figures in 2006 dollars. Revised February, 2010.

(3) - Annual emission reduction and levelized control cost of these alternatives is relative to current costs and pre-control unit MCR baseline emission rate. Revised February, 2010.

(4) - Increment based upon comparison between consecutive alternatives (points) from lowest to highest. Revised February, 2010.

(5) - The inclusion of tail-end and low-dust SCR technologies in this table does not constitute agreement that it is technically feasible to install these technologies on Unit 1 at Milton R. Young Station. The annual NOx removal and LTAC shown for a hypothetically-applied SCR system is based on assumptions that known or expected reasons for technical infeasibility for installation of the SCR equipment on this boiler are solvable. SCR technology is considered technically infeasible by Minnkota for application at MRYS per the October 2006 NO_X BACT Analysis Study report and subsequent submittals in response to comments by the NDDH, EPA, DOJ, and other parties, so this information for the hypothetical application of SCR alternatives is included for comparative purposes only. See Section 4.2.1.2.1 for details of Scenario A and Scenario B that assumes replacement of SCR catalyst after a specified number of hours of unit operation. Revised February, 2010.

TABLE 4-8SF – Dominant Controls Cost Curve Points for NO_X Control Alternatives - MRY Station Unit 1 - Shared Facilities SCR Projects

Alt. Label(1)	NOx Control Alternative	Levelized Total Annual Cost(2),(3) ($1,000/yr)	Annual Emission Reduction(3) (tpy)	Incremental Levelized Total Annual Cost(2),(4) ($1,000/yr)	Incremental Annual Emission Reduction(4) (tpy)	Incremental Control Cost Effectiveness ($/ton)(2),(4)

A	Advanced SOFA (ASOFA)	2,489	4,060	2,489	4,060	613

(1) - Alternative label has been assigned from highest to lowest unit NOx emission rate. Dominant controls cost curve points from lowest (ASOFA) to highest (TESCR w/ ASOFA – 16,000 hrs) are labeled the same as in Table 4-7SF, and on the graphs that accompany this table (Points B, C, and D were eliminated).

(2) - All cost figures in 2006 dollars. Revised February, 2010.

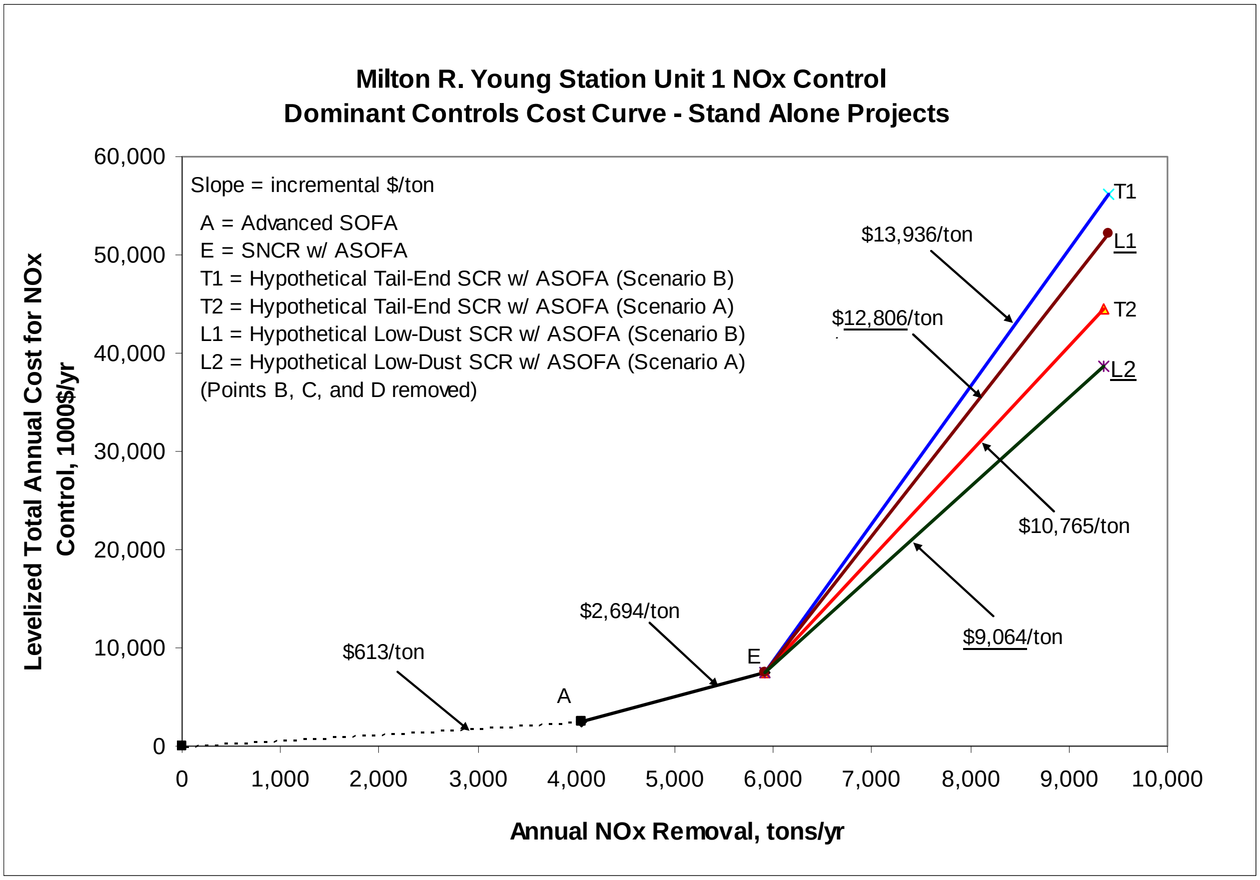
(3) - Annual emission reduction and levelized control cost of these alternatives is relative to current costs and pre-control unit MCR baseline emission rate. Revised February, 2010.

(4) - Increment based upon comparison between consecutive alternatives (points) from lowest to highest. Revised February, 2010.

(5) - The inclusion of tail-end and low-dust SCR technologies in this table does not constitute agreement that it is technically feasible to install these technologies on Unit 1 at Milton R. Young Station. The annual NOx removal and LTAC shown for a hypothetically-applied SCR system is based on assumptions that known or expected reasons for technical infeasibility for installation of the SCR equipment on this boiler are solvable. SCR technology is considered technically infeasible by Minnkota for application at MRYS per the October 2006 NO_X BACT Analysis Study report and subsequent submittals in response to comments by the NDDH, EPA, DOJ, and other parties, so this information for the hypothetical application of SCR alternatives is included for comparative purposes only. See Section 4.2.1.2.1 for details of Scenario A and Scenario B that assumes replacement of SCR catalyst after a specified number of hours of unit operation. Revised February, 2010.

Figures 4-2SA and 4-2SF contains a repetition of the levelized total annual cost and NO_X control information from Figures 4-1SA and 4-1SF for MRY Station Unit 1, with Point B (FLGR™ with ASOFA) , Point C (Lignite Reburn with ASOFA) and Point D (conventional gas reburn with ASOFA) removed. This is the dominant controls cost curve for MRY Station Unit 1 NO_X emissions alternatives.

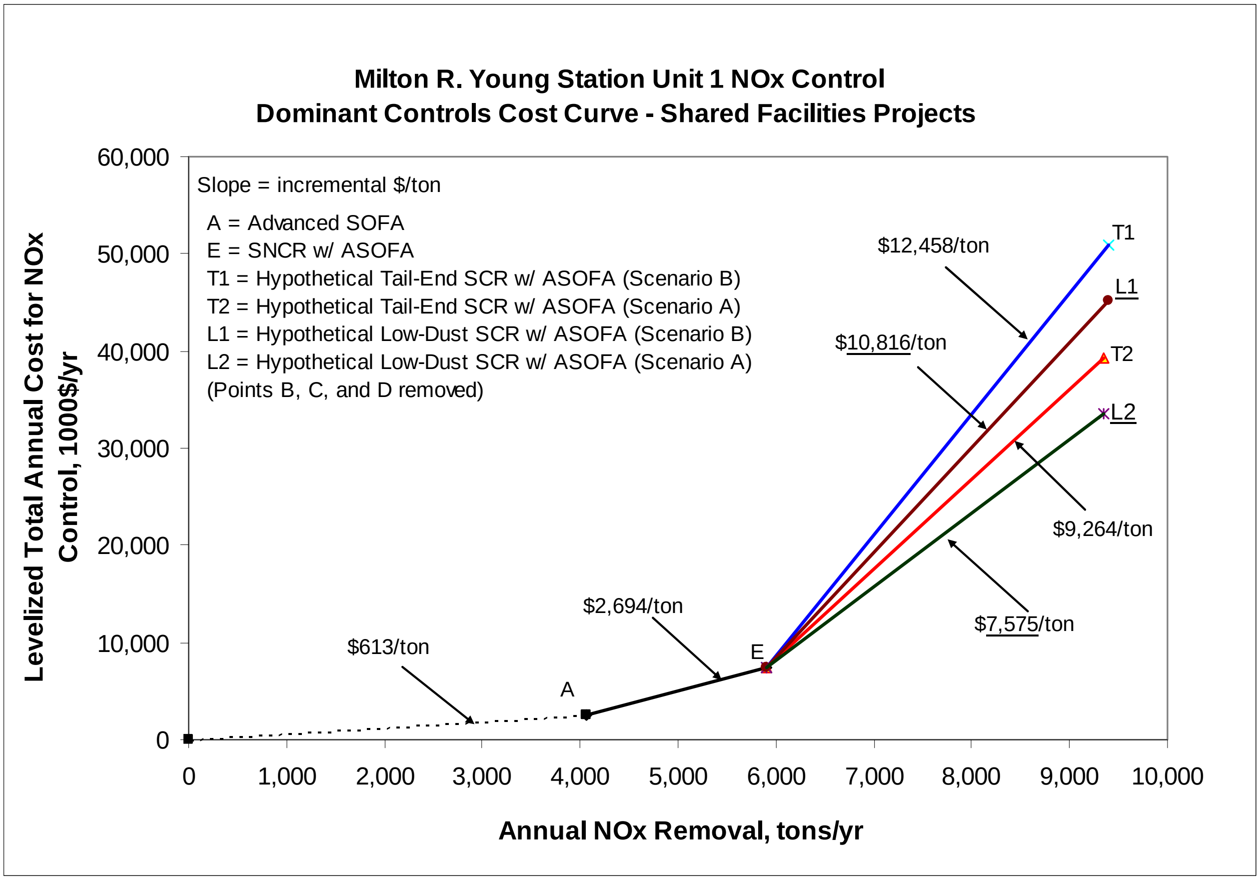
Figure 4-2SA – MRY Station Unit 1 NO_X Control Alternatives BACT Dominant Controls Cost Curve(1) - Stand Alone SCR Projects



(1) - All cost figures in 2006 dollars. Numbers are listed and qualifiers are noted in Table 4-8SA. Revised February, 2010.

(2) - The inclusion of tail-end and low dust SCR technologies in this figure does not constitute agreement that it is technically feasible to install these technologies on Unit 1 at Milton R. Young Station. The estimated annual NOx removal and LTAC shown for a hypothetically-applied SCR system is based on assumptions that known or expected reasons for technical infeasibility for installation and operation and maintenance of the SCR equipment on this boiler are solvable. SCR technology is considered technically infeasible by Minnkota for application at MRYS per the October 2006 NO_X BACT Analysis Study report and subsequent submittals in response to comments by the NDDH, EPA, DOJ, and other parties, so this information for the hypothetical application of SCR alternatives is included for comparative purposes only. See Section 4.2.1.2.1 for details of Scenario A and Scenario B that assumes replacement of SCR catalyst after a specified number of hours of unit operation.

Figure 4-2SF – MRY Station Unit 1 NO_X Control Alternatives BACT Dominant Controls Cost Curve(1) – Shared Facilities SCR Projects



(1) - All cost figures in 2006 dollars. Numbers are listed and qualifiers are noted in Table 4-8SF. Revised February, 2010.

(2) - The inclusion of tail-end and low dust SCR technologies in this figure does not constitute agreement that it is technically feasible to install these technologies on Unit 1 at Milton R. Young Station. The estimated annual NOx removal and LTAC shown for a hypothetically-applied SCR system is based on assumptions that known or expected reasons for technical infeasibility for installation and operation and maintenance of the SCR equipment on this boiler are solvable. SCR technology is considered technically infeasible by Minnkota for application at MRYS per the October 2006 NO_X BACT Analysis Study report and subsequent submittals in response to comments by the NDDH, EPA, DOJ, and other parties, so this information for the hypothetical application of SCR alternatives is included for comparative purposes only. See Section 4.2.1.2.1 for details of Scenario A and Scenario B that assumes replacement of SCR catalyst after a specified number of hours of unit operation.

As can be seen from a review of Tables 4-7SA and 4-7SF, the average levelized control cost effectiveness (called the unit control cost in this report) ranges from approximately $613/ton to $6,597/ton of MRYS Unit 1's NO_X emissions removed. The unit control cost for the hypothetically-applied Scenario A Tail End SCR w/ ASOFA case was $4,758/ton and for the hypothetically-applied Scenario B Tail End SCR w/ ASOFA case was $5,969/ton (stand alone projects). The unit control cost for the hypothetically-applied Scenario A Low-Dust SCR w/ ASOFA case was $~~3,944~~ 4,134/ton and for the hypothetically-applied Scenario B Low-Dust SCR w/ ASOFA case was $~~5,380~~ 5,552/ton (stand alone projects). The unit control cost for the hypothetically-applied Scenario A Tail End SCR w/ ASOFA case was $4,206/ton and for the hypothetically-applied Scenario B Tail End SCR w/ ASOFA case was $5,420/ton (shared facilities projects). The unit control cost for the hypothetically-applied Scenario A Low-Dust SCR w/ ASOFA case was $~~3,396~~ 3,586/ton and for the hypothetically-applied Scenario B Low-Dust SCR w/ ASOFA case was $~~4,835~~ 4,813/ton (shared facilities projects). Unit control costs for SNCR w/ ASOFA was $1,265/ton, more than twice that of ASOFA ($613/ton). It should be noted, however, that the very high estimated average control costs involve fuel lean gas reburn ($3,635/ton) and conventional gas reburn ($6,597/ton) technologies that were shown to be inferior options (not on the dominant controls cost curve) and thus were eliminated from further impacts analysis.

The incremental cost analysis indicates that from a cost effectiveness viewpoint, the SNCR with ASOFA alternative for MRYS Unit 1 incurs a significant annual (levelized) incremental cost compared to the ASOFA NO_X control technique. The slope from zero (baseline) to ASOFA (Point A) was $613/ton; the incremental cost per ton (slope) from ASOFA (Point A) to SNCR with ASOFA (Point E) was $2,694/ton for MRYS Unit 1. The incremental cost per ton (slope) from SNCR with ASOFA (Point E) to the top hypothetically-applied low-dust SCR case (Point L2, Scenario A) was $~~8,547~~ 9,064/ton (stand alone projects). The incremental cost per ton (slope) from SNCR with ASOFA (Point E) to the top hypothetically-applied tail end SCR case (Point T2, Scenario A) was $10,765/ton (stand alone projects). The incremental cost per ton (slope) from SNCR with ASOFA (Point E) to the second hypothetically-applied low-dust SCR case (Point L1, Scenario B) was $~~12,343~~ 12,806/ton (stand alone projects). The incremental cost per ton (slope) from SNCR with ASOFA (Point E) to the second hypothetically-applied tail end SCR case (Point T1, Scenario B) was $13,936/ton (stand alone projects). For shared projects, the incremental cost per ton (slope) from SNCR with ASOFA (Point E) to the top hypothetically-applied SCR cases were $~~7,058~~ 7,575/ton (low-dust Point L2, Scenario A) and $9,264/ton (tail end Point T2, Scenario A). For shared projects, the incremental cost per ton (slope) from SNCR with ASOFA (Point E) to the second hypothetically-applied SCR cases were $~~10,876~~ 10,816/ton (low-dust, Point L1, Scenario B) and $12,458/ton (tail end Point T1, Scenario B).

In the U.S. EPA's NSR Manual, the EPA does not specify acceptable or unacceptable ranges for average (unit control costs) and incremental cost effectiveness values. EPA's NSR Manual however, does specifically address the standard to be used when rejecting a candidate technology on the basis of adverse economic impact:

> "Consequently, where unusual factors exist that result in cost/economic impacts beyond the range normally incurred by other sources in that category, the technology

> can be eliminated provided the applicant has adequately identified the circumstances, including the cost or other analyses, that show what is significantly different about the proposed source."[34]

This supplemental report for the MRYS NOx BACT Analysis has clearly established the circumstances, including the economic impacts, which would make the hypothetical application of TESCR or LDSCR to MRYS Unit 1 significantly more expensive than SCR costs normally incurred by other coal-fired steam electric generating units. The following information further supports EPA's own statements regarding the costs "normally incurred by other sources". The EPA's technical support document issued with the final Regional Haze Regulations and BART Guidelines estimated an average control cost for SCR applied to MRYS Unit 1 of $549 per ton[35]. The unadjusted unit capital cost versus capacity factor assumed by the EPA for SCR retrofits applied to cyclone boilers in the cost-effectiveness analysis used for establishing presumptive BART[36] was $100/kW. The EPA's cost-effectiveness analysis used for establishing presumptive BART stated that "applying SCR for coal-fired cyclone units is typically less than $1500 a ton, and that the average cost-effectiveness is $900 per ton" [37]. The site-specific control costs estimated for hypothetical application of tail-end and low-dust SCR alternatives to MRYS Unit 1 are significantly higher than the EPA's cost-effectiveness analysis for conventional SCR technologies included in the technical support document issued with the final Regional Haze Regulations and BART Guidelines discussed above.

Also, the use of incremental cost effectiveness is warranted per the final 2005 RHR/BART Guidelines, which state "the greater the number of possible control options that exist, the more weight should be given to the incremental costs vs. average costs". Also in the final 2005 RHR/BART Guidelines, "the average cost for each [of two options, A and B]… may be deemed to be reasonable. However, the incremental cost…of the additional emissions reductions to be achieved by control B may be very great. In such an instance, it may be inappropriate to chose control B, based on its higher incremental costs, even though its average cost may be considered reasonable".[38]

L1	Hypothetical Low-Dust SCR w/ ASOFA – Scenario B[7]	0.053	145	533	9,401	93.8[8]	180,739	29,178	52,193	5,552
E	SNCR w/ ASOFA	0.355	975	4,025	5,909	58.1	8,113	5,417	7,472	1,265
D	Gas Reburn w/ ASOFA	0.374	1,025	4,275	5,659	56.0	18,006	28,641	37,334[9]	6,597
C	Lignite Reburn w/ ASOFA	0.385	1,058	4,343	5,591	54.6	46,656	5,862	11,388[9]	2,037
B	FLGR w/ ASOFA	0.460	1,261	5,260	4,674	45.9	10,639	12,863	16,990[9]	3,635
A	Advanced SOFA (ASOFA)	0.513	1,409	5,874	4,060	39.5	4,277	1,695	2,489	613
	Baseline	0.849	2,330	9,934	0	0.0	0	0	0	

(1) - Alternative label has been assigned from highest to lowest unit NOx emission rate.

(2) - Estimated NO_X control level reductions relative to average annual unit emission baseline of 0.849 lb/mmBtu at 2,744 mmBtu/hr MCR heat input. Emissions are calculated from unit emission rates, control percentage, hourly heat input, and annual hrs/yr operation compared to pre-control baseline based on annual operation at a gross unit electrical output of 244.45 MWg and assumes a 97.3% average annual availability. Values from reported emission data for the 12 month operating period during 2001-2005 with the highest rolling summation of NOx pounds.

(3) - Installed capital cost is estimated for determination of total capital cost for a particular technology or combination, assuming 257 MWg unit capacity rating. All cost figures in 2006 dollars. Costs for gas reburn options include high-pressure natural gas supply pipeline installed capital cost of $8,075,000 for CGR and $4,038,000 for FLGR. Costs for increased PM collection capacity included in lignite reburn option are $23,561,000 for installed capital cost.

(4) - Annual operating and maintenance cost for a particular technology or combination is compared to unit baseline operation at a gross unit electrical output of 244.45 MWg and assumes a 96.6% average running plant capacity ratio compared to nominal unit gross electrical output capacity of 253 MWg. All cost figures in 2006 dollars. Costs for increased PM collection capacity included in lignite reburn option are $1,909,000/yr for annual O&M cost. Revised February, 2010.

(5) - Levelized Total Annual Cost = Annualized Installed Capital Cost + Levelized Annual O&M cost. Annualized capital cost = Installed capital cost x 0.08718 annualized capital cost factor. Levelized annual O&M cost = Annual O&M cost x 1.24873 annualized O&M cost factor. Revised February, 2010.

(6) - Average Control Cost Effectiveness ($/ton) is the Levelized Total Annual Cost ($/yr) divided by Annual Emission Reduction (tons). All cost figures in 2006 dollars. Revised February, 2010.

(7) - The inclusion of tail-end and low-dust SCR technologies in this table does not constitute agreement that it is technically feasible to install these technologies on Unit 1 at Milton R. Young Station. The estimated annual NOx removal and LTAC shown for a hypothetically-applied SCR system is based on assumptions that known or expected reasons for technical infeasibility for installation and operation and maintenance of the SCR equipment on this boiler are solvable. SCR technology is considered technically infeasible by Minnkota for application at MRYS per the October 2006 NO_X BACT Analysis Study report and subsequent submittals in response to comments by the NDDH, EPA, DOJ, and other parties, so this information for the hypothetical application of SCR alternatives is included for comparative purposes only. See Section 4.2.1.2.1 for details of Scenario A and Scenario B that assumes replacement of SCR catalyst after a specified number of hours of unit operation. Revised February, 2010.

(8) - The stated overall control percentage includes the anticipated long-term emission reduction of 90% design removal from a baseline of 0.51 lb/mmBtu resulting from an advanced separated overfire air system, with air-staged low-NO_X cyclone combustion. Without a separated overfire air system operation or any other technique employed, the assumed emission rate would be 0.085 lb/mmBtu, for an overall reduction of 90 percent from a baseline of 0.849 lb/mmBtu.

(9) - LTAC for reburn options include high-pressure natural gas supply pipeline annualized capital cost of $704,000/yr for CGR and $352,000 for FLGR; LTAC for increased PM collection capacity included in lignite reburn option are $2,054,000 for annualized capital cost plus $2,384,000/yr for annualized O&M cost, for a total of $4,438,000/yr.

TABLE 4-9SF – Estimated Emissions and Economic Impacts Summary for NO$_X$ Control Alternatives - MRY Station Unit 1 – Shared Facilities SCR Projects

Summary of Estimated Annual Emissions and Economics for NOx Control Alternatives Evaluated for Milton R. Young Station Unit 1 – Shared Facilities Projects

(6) - Average Control Cost Effectiveness ($/ton) is the Levelized Total Annual Cost ($/yr) divided by Annual Emission Reduction (tons). All cost figures in 2006 dollars. Revised February, 2010.

(7) - The inclusion of tail-end and low-dust SCR technologies in this table does not constitute agreement that it is technically feasible to install these technologies on Unit 1 at Milton R. Young Station. The estimated annual NOx removal and LTAC shown for a hypothetically-applied SCR system is based on assumptions that known or expected reasons for technical infeasibility for installation and operation and maintenance of the SCR equipment on this boiler are solvable. SCR technology is considered technically infeasible by Minnkota for application at MRYS per the October 2006 NO$_X$ BACT Analysis Study report and subsequent submittals in response to comments by the NDDH, EPA, DOJ, and other parties, so this information for the hypothetical application of SCR alternatives is included for comparative purposes only. See Section 4.2.1.2.1 for details of Scenario A and Scenario B that assumes replacement of SCR catalyst after a specified number of hours of unit operation. Revised February, 2010.

(8) - The stated overall control percentage includes the anticipated long-term emission reduction of 90% design removal from a baseline of 0.51 lb/mmBtu resulting from an advanced separated overfire air system, with air-staged low-NO$_X$ cyclone combustion. Without a separated overfire air system operation or any other technique employed, the assumed emission rate would be 0.085 lb/mmBtu, for an overall reduction of 90 percent from a baseline of 0.849 lb/mmBtu.

(9) - LTAC for reburn options include high-pressure natural gas supply pipeline annualized capital cost of $704,000/yr for CGR and $352,000 for FLGR; LTAC for increased PM collection capacity included in lignite reburn option are $2,054,000 for annualized capital cost plus $2,384,000/yr for annualized O&M cost, for a total of $4,438,000/yr.

The other elements of the fourth step of a BACT analysis following economic impacts are to evaluate the following impacts of feasible emission controls:

(1) The energy impacts.
(2) The environmental impacts.

4.2.2 ENERGY IMPACTS OF HYPOTHETICALLY-APPLIED SCR NO_X CONTROL ALTERNATIVES FOR MRY STATION UNIT 1

Operation of the NO_X control technologies on the dominant controls cost curve for potential application at the Milton R. Young Station impose direct impacts on the consumption of energy required for the production of electric power at the facility. The details of estimated energy usage and costs for the previously-evaluated NO_X control alternatives were described and summarized in Section 3.4.2 and Appendix C3 of the October 2006 NOx BACT Analysis Study report[39].

The hypothetical application of Tail End and Low-Dust SCR w/ ASOFA alternatives involve higher energy consumption compared with the existing operation of MRYS Unit 1. New induced draft booster fan electrical power demand is needed due to the estimated additional flue gas pressure drop resulting from hypothetical application of SCR reactor, ductwork, and gas-to-gas heat exchangers. The additional auxiliary electric power demand for the hypothetical application of TESCR and LDSCR equipment were calculated to be 9.7 MW and 8.0 MW, respectively, using estimated annual average electrical loads of the booster fan, urea-to-ammonia conversion fired heater combustion/dilution air fan, direct-fired flue gas reheat burner combustion air fan, and service and sootblowing air compressor equipment and related auxiliary equipment.

Preliminary conceptual design details were developed for these alternatives. An estimated additional 12 inches w.c. of flue gas pressure drop was assumed for each hypothetical application of low-dust SCR system, and an estimated additional 19 inches w.c. of flue gas pressure drop was assumed for the hypothetical application of tail end SCR system. Equipment and ductwork arrangements and expected fouling of the catalyst for the hypothetical application of SCR system ductwork, reactor, and gas-gas reheater changes may cause significantly more restrictive flow paths. Thus the electrical power usage estimated here may be too low.

---

[39] Ibid Reference number 3, October 2006, pages 3-31 through 3-35, and Appendix pages C3-7 through C3-10.

The expected loss of electrical power generation from these reductions in net output was included as a cost, assuming $35 per megawatt-hour for replacement electrical power. Energy impacts of installing hypothetical application of low-dust and tail end SCR alternatives for NO_X control were included in the O&M cost section (4.2.1.2.1) of this supplemental analysis as Tables C.4-2 through C.4-4.

Aqueous urea solution was assumed to be the preferred, readily available and transportable source of the amine reagent needed to supply ammonia to the SCR reactor catalyst for the low-dust and tail-end SCR alternatives. A urea-to-ammonia conversion system dedicated for each SCR reactor was also assumed. This conversion process will use a natural gas-fired burner that mixes the combustion products at high temperature with the injected aqueous urea solution to thermally decompose the urea, producing gaseous ammonia to supply to the reactors' ammonia injection grids. Gaseous ammonia is the required amine reagent that the catalyst in the SCR reactors uses to convert nitrogen oxides to elemental nitrogen and water vapor. Ammonia (from urea conversion) is supplied and consumed continuously on demand while the SCR NO_X reduction process is in operation. Natural gas is fired continuously during the urea-to-ammonia conversion system operation.

Final reactor inlet flue gas reheat systems are required for the hypothetical application of tail end and low-dust SCR with ASOFA alternatives. A natural gas-fired duct burner that injects high temperature combustion products directly into the flue gas discharged from each SCR gas/gas heat exchanger was assumed for raising the reactor inlet temperature to 600ºF before ammonia injection and NOx reduction can occur in each SCR reactor. Natural gas is fired continuously for flue gas reheating during SCR system operation.

TABLE 4-10 – Energy Impacts for NO_X Control Alternatives - MRY Station Unit 1

A	Advanced SOFA (ASOFA)	0	0	0	0	0

(1) - Alternative label has been assigned from highest to lowest unit NOx emission rate. Alternatives are labeled the same as in Table 4-9.

(2) - The inclusion of tail-end and low-dust SCR technologies in this table does not constitute agreement that it is technically feasible to install these technologies on Unit 1at Milton R. Young Station. The annual NOx removal and LTAC shown for a hypothetically-applied SCR system is based on assumptions that known or expected reasons for technical infeasibility for installation of the SCR equipment on this boiler are solvable. SCR technology is considered technically infeasible by Minnkota for application at MRYS per the October 2006 NO_X BACT Analysis Study report and subsequent submittals in response to comments by the NDDH, EPA, DOJ, and other parties, so this information for the hypothetical application of SCR alternatives is included for comparative purposes only. See Section 4.2.1.2.1 for details of Scenario A and Scenario B that assumes replacement of SCR catalyst after a specified number of hours of unit operation. Revised February, 2010.

(3) – Estimated annual natural gas usage for urea-to-ammonia conversion based on adjustments to preliminary budgetary equipment vendor proposals and process calculations. TESCR and LDSCR rate = 4.27 mmBtu/hr for one reactor.

(4) – Estimated annual natural gas usage for flue gas final reheat based on adjustments to preliminary vendor process calculations. TESCR rate = 60.3 mmBtu/hr for one reactor; LDSCR rate = ~~31~~ 54.5 mmBtu/hr for one reactor. Rev 2/10.

(5) – Natural gas burned for reburn alternatives is assumed to replace coal, no boiler heat rate penalty assumed. Lignite reburn is assumed to burn the same total amount of coal in the boiler as without coal reburn. Revised February, 2010.

(6) - Additional coal burned is due to the urea dilution water injected directly into the boiler’s upper furnace, decreasing heat available for steam production and electricity generation, at a net loss of 900 Btu/lb of water for evaporation. See Appendix C3 in the 2006 NO_X BACT Analysis Study report for additional details.

(7) - Annual O&M costs include these values multiplied by the number of hours per year of operation and assume $7.98 per mmBtu for natural gas and $0.71 per mmBtu for coal. Revised February, 2010.

4.2.3 ENVIRONMENTAL IMPACTS OF HYPOTHETICALLY-APPLIED SCR NO_X CONTROL ALTERNATIVES FOR MRY STATION UNIT 1

Operation of the NO_X control technologies on the dominant controls cost curve for potential application at the Milton R. Young Station would impose direct and indirect impacts on the environment. The most pronounced direct environmental impact expected from operation of any of the NO_X control options considered is the reduction of ozone and improvement in atmospheric visibility (i.e., reduced visibility impairment) downwind of the facility. Environmental impacts of previously-evaluated NO_X control alternatives were described and summarized in Section 3.4.3 of the October 2006 NOx BACT Analysis Study report.[40]

There would be a favorable environmental impact from potential reduction of annual unit operating time by approximately two percent due to cyclone slag issues associated with air-staged cyclones/ASOFA system operation and by between five percent and 17 percent due to catalyst management and SCR equipment maintenance-related issues for the various low-dust and tail end SCR alternatives. The impact of fewer annual hours of operation will be to decrease the annual amount (tons) of nitrogen oxides emitted, by between approximately 0.2 percent and one percent overall compared to baseline operation. However, generation of replacement electrical power at other powerplants will negate most of these emission reductions.

Operation of the hypothetical application of SCR systems is not expected to significantly impact emissions of carbon monoxide (CO) or volatile organic compounds (VOCs). Emissions from the urea-to-ammonia conversion and flue gas reheat natural gas-fired burners are additive and included in the flue gas entering the SCR reactor in each hypothetical application of SCR case.

Operation of any SCR system will normally cause a small amount of unreacted ammonia to be emitted. The amount of ammonia slip produced by an SCR depends on the reagent utilization and the location of the injection points. Higher SCR NO_X reduction performance involves greater amounts of reagent usage and ammonia slip. This is typically controlled to less than 2 ppmvd, especially when the possible formation of sulfates such as ammonium sulfate $[(NH_4)_2SO_4]$ and ammonium bisulfate $[NH_4HSO_4]$ will be more problematic at higher slip levels. Sulfur trioxide (SO_3) formed during combustion in the boiler can combine with ammonia during passage through the catalyst to form the sulfates downstream.

---

[40] Ibid Reference number 3, October 2006, pages 3-35 through 3-37.

Unreacted ammonia (“slip”) from SCR operation will not be collected downstream of the tail end SCR reactor. The wet flue gas desulfurization absorber downstream of the low-dust SCR reactor may reduce ammonia slip. Any remaining ammonia slip that is not collected or condensed in the air pollution control system will be emitted from the stack as an aerosol or condensable particulate. This has the potential to increase atmospheric visibility impairment downwind of the facility compared with a pristine condition.

Sulfur dioxide (SO_2) formed during combustion in the boiler can combine with oxygen during passage through the hypothetical application of tail end and low-dust SCR catalyst to form additional sulfur trioxide (SO_3) emissions. SO_3 can subsequently combine with water (H_2O) to form sulfuric acid (H_2SO_4), usually in the form of a mist. Wet flue gas scrubbing to remove SO_2 is not highly effective in removing SO_3 created in an upstream low-dust SCR, so higher sulfate emissions will result unless a precipitating reaction with ammonia or condensation in the downstream gas-gas reheater or ductwork occurs. SO_3 and H_2SO_4 can have significant negative far-field impairment impacts on atmospheric visibility if they are above threshold concentrations and not controlled. Tail end SCRs can also cause a small amount of SO_3 to be created as the remaining SO_2 not removed by the wet lime flue gas desulfurization systems will pass through the catalyst and some will be oxidized. It is not known whether the high concentration of alkalinity in the form of sodium aerosol particles will effectively eliminate the remaining SO_3 downstream of the low-dust and tail end SCR systems.

Catalyst from the hypothetical application of SCR reactors will require regular replacement, requiring disposal of the spent catalyst materials or chemical cleaning to remove deposits to allow reuse or regeneration. Hauling spent catalyst to a catalyst rejuvenation facility or an authorized landfill may be required, producing additional liquid and solid wastes and vehicle exhaust emissions.

Because railroad service is not available to MRYS, shipments of amine reagent (concentrated urea solution) for consumption by the hypothetical application of SCR reactors will require additional truck traffic between the supply facility and plant, producing more emissions from vehicle exhaust.

4.2.4 SUMMARY OF ECONOMIC, ENERGY AND ENVIRONMENTAL IMPACTS OF HYPOTHETICALLY-APPLIED SCR NO_X CONTROL ALTERNATIVES FOR MRY STATION UNIT 1

The economic, energy, and environmental impacts of each NO_X control technology on the dominant controls cost curve for potential application at the Milton R. Young Station evaluated for this study are summarized in this Section. Table 3-18 summarized the various impacts discussed in Sections 3.4.1 through 3.4.3 of the October 2006 NO_X BACT Analysis Study report[41]. This supplemental economic analysis examined the estimated capital cost of four hypothetically-applied SCR cases and previously-analyzed feasible NO_X control alternatives and any other powerplant upgrade costs necessary to implement the alternatives. In addition, the economic analysis examined the operating and maintenance costs associated with each NO_X control technology evaluated. These costs were then combined into the levelized total annual cost for a comparative assessment of the total implementation cost of each alternative. Finally, as part of the top-down analysis, a dominant controls cost curve was plotted and the unit control cost for each remaining alternative was evaluated. Four hypothetically-applied SCR cases and two previously-analyzed feasible alternatives were on the dominant controls cost curve and the latter were identified as the more cost effective alternatives. The four hypothetically-applied SCR cases and two previously-analyzed feasible BACT NO_X control alternatives were evaluated for incremental cost, energy, and environmental impacts applicable to Milton R. Young Station Unit 1. The results are summarized in Tables 4-11SA and 4-11SF.

The unit control cost for the hypothetical application of Scenario A Tail End SCR w/ ASOFA case was $4,758/ton and was $5,969/ton for the hypothetical application of Scenario B Tail End SCR w/ ASOFA case (stand alone projects). The unit control cost for the hypothetical application of Scenario A Low-Dust SCR w/ ASOFA case was $~~3,944~~ 4,134/ton and was $~~5,380~~ 5,552/ton for the hypothetical application of Scenario B Low-Dust SCR w/ ASOFA case (stand alone projects). The unit control cost for the hypothetical application of Scenario A Tail End SCR w/ ASOFA case was $4,206/ton and was $5,420/ton for the hypothetical application of Scenario B Tail End SCR w/ ASOFA case (shared facilities projects). The unit control cost for the hypothetical application of Scenario A Low-Dust SCR w/ ASOFA case was $~~3,396~~ 3,586/ton and was $~~4,835~~ 4,813/ton for the hypothetical application of Scenario B Low-Dust SCR w/ ASOFA case (shared facilities projects). Unit control cost for SNCR w/ ASOFA was $1,265/ton, more than twice that of ASOFA ($613/ton). The UCCs for the hypothetical application of SCR are approximately ~~270~~ 280 to 470 percent of the UCC for SNCR w/ ASOFA ($1,265/ton), and approximately ~~550~~ 580 to 970 percent of ASOFA's UCC ($613/ton).

The incremental cost analysis indicates that from a cost effectiveness viewpoint, the SNCR with ASOFA alternative for MRYS Unit 1 incurs a significant annual (levelized) incremental cost compared to the ASOFA NO_X control technique. The slope from zero (baseline) to ASOFA (Point A) was $613/ton; the

---

[41] Ibid Reference number 3, October 2006, pages 3-20 through 3-38.

incremental cost per ton (slope) from ASOFA (Point A) to SNCR with ASOFA (Point E) was $2,694/ton for MRYS Unit 1. The incremental cost per ton (slope) from SNCR with ASOFA (Point E) to the top hypothetical application of low-dust SCR case (Point L2, Scenario A) was $~~8,547~~ 9,064/ton (stand alone projects). The incremental cost per ton (slope) from SNCR with ASOFA (Point E) to the top hypothetical application of tail end SCR case (Point T2, Scenario A) was $10,765/ton (stand alone projects). The incremental cost per ton (slope) from SNCR with ASOFA (Point E) to the second hypothetical application of low-dust SCR case (Point L1, Scenario B) was $~~12,343~~ 12,806/ton (stand alone projects). The incremental cost per ton (slope) from SNCR with ASOFA (Point E) to the second hypothetical application of tail end SCR case (Point T1, Scenario B) was $13,936/ton (stand alone projects). For shared projects, the incremental cost per ton (slope) from SNCR with ASOFA (Point E) to the top hypothetical application of SCR cases were $~~7,058~~ 7,575/ton (low-dust Point L2, Scenario A) and $9,264/ton (tail end Point T2, Scenario A). For shared projects, the incremental cost per ton (slope) from SNCR with ASOFA (Point E) to the second hypothetical application of SCR cases were $~~10,876~~ 10,816/ton (low-dust, Point L1, Scenario B) and $12,458/ton (tail end Point T1, Scenario B).

The incremental unit control cost per ton (slope) from SNCR with ASOFA to the hypothetical application of SCR with ASOFA cases are approximately ~~260~~ 280 to 520 percent of the incremental UCC per ton (slope) between ASOFA and SNCR with ASOFA ($2,694/ton). The incremental UCCs from SNCR with ASOFA to the hypothetical application of SCR with ASOFA cases is between ~~11~~ 12 and 23 times the incremental UCC for ASOFA from the pre-control baseline ($613/ton).

In the U.S. EPA's NSR Manual, the EPA does not specify acceptable or unacceptable ranges for average (unit control costs) and incremental cost effectiveness values. EPA's NSR Manual however, does specifically address the standard to be used when rejecting a candidate technology on the basis of adverse economic impact:

> "Consequently, where unusual factors exist that result in cost/economic impacts beyond the range normally incurred by other sources in that category, the technology can be eliminated provided the applicant has adequately identified the circumstances, including the cost or other analyses, that show what is significantly different about the proposed source."[42]

This supplemental report for the MRYS NOx BACT Analysis has clearly established the circumstances, including the economic impacts, which would make the hypothetical application of TESCR or LDSCR to

---

[42] Ibid Reference number 2, Section IV.D.2.c.

MRYS Unit 1 significantly more expensive than SCR costs normally incurred by other coal-fired steam electric generating units. The following information further supports EPA's own statements regarding the costs "normally incurred by other sources". The EPA's technical support document issued with the final Regional Haze Regulations and BART Guidelines was considered relevant for control cost-effectiveness comparison. The EPA's cost-effectiveness analysis used for establishing presumptive BART stated that "applying SCR for coal-fired cyclone units is typically less than $1500 a ton, and that the average cost-effectiveness is $900 per ton" [43]. EPA's technical support document estimated an average control cost for SCR applied to MRYS Unit 1 of $549 per ton[44]. The unadjusted unit capital cost factor assumed by the EPA for SCR retrofits applied to cyclone boilers in the cost-effectiveness analysis used for establishing presumptive BART[45] was $100/kW. The estimated "stand alone" and "shared facilities" installed capital costs for the hypothetical application of Low-Dust SCR w/ ASOFA cases at MRYS Unit 1 are $543 to $703/kW, which is more than 500 percent of the EPA's number. The estimated "stand alone" and "shared facilities" installed capital costs for the hypothetical application of Tail End SCR w/ ASOFA cases are $706 to $867/kW, which is more than 700 percent of the EPA's number. Also stated in the final RHR/BART Guidelines, "the average cost for each [of two options, A and B]… may be deemed to be reasonable. However, the incremental cost…of the additional emissions reductions to be achieved by control B may be very great. In such an instance, it may be inappropriate to chose control B, based on its higher incremental costs, even though its average cost may be considered reasonable".[46]

4.2.5 CONCLUSIONS

The site-specific control costs estimated for application of hypothetical application of tail-end and low-dust SCR alternatives to MRYS Unit 1 are significantly higher than the EPA's cost-effectiveness analysis for conventional SCR technologies included in the technical support document issued with the final Regional Haze Regulations and BART Guidelines discussed above.

The expected severity of catalyst blinding and pluggage from particulate matter and flue gases emitted from cyclone-fired boilers burning North Dakota lignite precludes the technical feasibility for successful application of such SCR technologies on the electric generating units (EGUs) at the Milton R. Young Station. Not withstanding the technical discussion of SCR technology infeasibility and technical details

previously provided in Appendix A1 and Appendix B[47] of the initial NO_X BACT Analysis report and subsequent submittals in response to comments by the NDDH, EPA, DOJ, and other parties, this supplemental analysis concludes that the estimated capital and O&M costs for four variations of hypothetically-applied tail-end and low-dust SCR technology alternatives are significantly beyond the normal range of costs incurred, as compared to cost analysis values included in EPA's technical support document issued with the final Regional Haze Regulations and BART Guidelines[48,49]. Average control cost effectiveness for each hypothetical application of SCR control technology case is a minimum of approximately three times the unit control costs of the previously-analyzed highest-performing feasible control alternative recommended as BACT for MRYS Unit 1 (SNCR with ASOFA). Incremental control cost effectiveness for each hypothetical application of SCR control technology case is a minimum of approximately three times the incremental control costs of the previously-analyzed highest-performing feasible control alternative recommended as BACT for MRYS Unit 1 (SNCR with ASOFA).

There is an expected decrease in capacity and availability to generate electrical power due to the hypothetical application of low-dust and tail end SCR alternatives. A five to 17 percent decrease in the number of hours of annual operation, and approximately 3% drop in annual plant capacity (net electrical output or MW_n) during operation of the MRYS Unit 1 system are expected if the hypothetical application of low-dust or tail end SCR alternatives were installed. There are also substantial expected negative energy impacts for each hypothetical application of SCR control technology case. Additional auxiliary electrical power demands of approximately 8 to 10 MW will result. This estimate of electrical power usage may be too low. This higher electrical power consumption and lower electrical power generation by MRYS Unit 1 will require additional replacement electrical power to be generated elsewhere.

Natural gas is fired continuously during the urea-to-ammonia conversion system operation for the hypothetical application of Tail End and Low-Dust SCR with ASOFA alternatives.

Final reactor inlet flue gas reheat systems are required for the hypothetical application of Tail End and Low-Dust SCR with ASOFA alternatives. Natural gas is fired continuously for flue gas reheating during SCR system operation for raising the reactor inlet temperature to ~~600ºF~~ minimum operating temperature

(580ºF for low-dust, 563ºF for tail-end SCRs) before ammonia injection and NOx reduction can occur in the SCR reactor.

The site-specific control costs estimated for application of hypothetical application of tail-end and low-dust SCR alternatives to MRYS Unit 1 are significantly higher than the EPA's cost-effectiveness analysis for conventional SCR technologies included in the technical support document issued with the final Regional Haze Regulations and BART Guidelines[50]. SCR technologies of all three types identified in the October 2006 NO_X BACT Analysis Study report should be excluded from consideration for NO_X control at MRYS due to unacceptably high average and incremental cost per ton of pollutant removal based on the supplemental analysis provided herein. Therefore the conclusions regarding NOx BACT as expressed in the original October 2006 BACT Analysis for MRYS Unit 1 are confirmed.

The economic, energy, and environmental impacts of each NO_X control technology on the dominant controls cost curve for potential application to Unit 1 at the Milton R. Young Station evaluated for this study are summarized in Tables 4-11SA and 4-11SF.

---

T1	Hypothetical Tail End SCR w/ ASOFA – Scenario B(10)	0.053	145	536	9,398	222,864	29,361	56,095	5,969	13,936	9,685	342,358,537	Flyash UBC, catalyst disposal	CO, NH_3
L2	Hypothetical Low-Dust SCR w/ ASOFA – Scenario A(10)	0.053	145	586	9,348	180,739	18,332	38,649	4,134	9,064	8,012	169,418,356	Flyash UBC, catalyst disposal	CO, NH_3
L1	Hypothetical Low-Dust SCR w/ ASOFA – Scenario B(10)	0.053	145	533	9,401	180,739	29,178	52,193	5,552	12,806	8,012	341,140,028	Flyash UBC, catalyst disposal	CO, NH_3
E	SNCR w/ ASOFA	0.355	975	4,025	5,909	8,113	5,417	7,472	1,265	2,694	73	68,243,017	Flyash UBC	CO, NH_3
A	Advanced SOFA (ASOFA)	0.513	1,409	5,874	4,060	4,277	1,695	2,489	613	613	1	46,594,605	Flyash UBC	CO
	Baseline	0.849	2,330	9,934	0	0	0	0						

(1) - Alternative label has been assigned from highest to lowest unit NOx emission rate.

(2) - Estimated NO_X control level reductions relative to average annual emission baseline of 0.849 lb/mmBtu at 2,744 mmBtu/hr heat input. Emissions are calculated from unit emission rates, control percentage, hourly heat input, and annual hrs/yr operation compared to pre-control baseline based on annual operation at a gross unit electrical output of 244.5 MWg and assumes a 97.3% average annual availability.

(3) - Installed capital cost is estimated for determination of total capital cost for a particular technology or combination, assuming 257 MWg unit capacity rating. All cost figures in 2006 dollars.

(4) - Annual operating and maintenance cost for a particular technology or combination is compared to unit baseline operation at a gross unit electrical output of 244.5 MWg and assumes a 97.3% average annual availability, which is the highest consecutive 12-months of operation from 2001-2005. All cost figures in 2006 dollars. Revised February, 2010.

(5) - Levelized Total Annual Cost = Annualized Installed Capital Cost + Levelized Annual O&M cost. Annualized capital cost = Installed capital cost x 0.08718 annualized capital cost factor. Levelized annual O&M cost = Annual O&M cost x 1.24873 annualized O&M cost factor. Revised February, 2010.

(6) - Average Control Cost Effectiveness ($/ton) is the Levelized Total Annual Cost ($/yr) divided by Annual Emission Reduction (tons/yr). All cost figures in 2006 dollars. Revised February, 2010.

(7) - Incremental Control Cost Effectiveness ($/ton) is the difference in LTAC between the next most stringent alternative divided by the emissions reduction. All cost figures in 2006 dollars. Revised February, 2010.

(8) - Energy impacts are incremental auxiliary electrical power demand (kW) and annual power usage plus generation lost due to negative unit reliability (fewer hours per year of operation) resulting from each control alternative (kW-hrs/yr) compared to the pre-control baseline.

(9) - Environmental impacts summarize expected non-air effects and potential toxic air emissions resulting from control alternative compared to the pre-control baseline. Flyash unburned carbon content may increase with air-staging cyclones; carbon monoxide concentrations may increase an insignificant amount with air-staging cyclones. Excess unreacted ammonia (slip) expected from SNCR technology and the hypothetical application of SCR technology cases.

(10) - The inclusion of tail-end and low-dust SCR technologies in this table does not constitute agreement that it is technically feasible to install these technologies on Unit 1 at Milton R. Young Station. The estimated annual NOx removal and LTAC shown for a hypothetically-applied SCR system is based on assumptions that known or expected reasons for technical infeasibility for installation and operation and maintenance of the SCR equipment on this boiler are solvable. SCR technology is considered technically infeasible by Minnkota for application at MRYS per the October 2006 NO_X BACT Analysis Study report and subsequent submittals in response to comments by the NDDH, EPA, DOJ, and other parties, so this information for the hypothetical application of SCR alternatives is included for comparative purposes only. See Section 4.2.1.2.1 for details of Scenario A and Scenario B that assume replacement of SCR catalyst after a specified number of hours of unit operation.

(1) - Alternative label has been assigned from highest to lowest unit NOx emission rate.

(2) - Estimated NO_X control level reductions relative to average annual emission baseline of 0.849 lb/mmBtu at 2,744 mmBtu/hr heat input. Emissions are calculated from unit emission rates, control percentage, hourly heat input, and annual hrs/yr operation compared to pre-control baseline based on annual operation at a gross unit electrical output of 244.5 MWg and assumes a 97.3% average annual availability.

(3) - Installed capital cost is estimated for determination of total capital cost for a particular technology or combination, assuming 257 MWg unit capacity rating. All cost figures in 2006 dollars.

(4) - Annual operating and maintenance cost for a particular technology or combination is compared to unit baseline operation at a gross unit electrical output of 244.5 MWg and assumes a 97.3% average annual availability, which is the highest consecutive 12-months of operation from 2001-2005. All cost figures in 2006 dollars. Revised February, 2010.

(5) - Levelized Total Annual Cost = Annualized Installed Capital Cost + Levelized Annual O&M cost. Annualized capital cost = Installed capital cost x 0.08718 annualized capital cost factor. Levelized annual O&M cost = Annual O&M cost x 1.24873 annualized O&M cost factor. Revised February, 2010.

(6) - Average Control Cost Effectiveness ($/ton) is the Levelized Total Annual Cost ($/yr) divided by Annual Emission Reduction (tons/yr). All cost figures in 2006 dollars. Revised February, 2010.

(7) - Incremental Control Cost Effectiveness ($/ton) is the difference in LTAC between the next most stringent alternative divided by the emissions reduction. All cost figures in 2006 dollars. Revised February, 2010.

(8) - Energy impacts are incremental auxiliary electrical power demand (kW) and annual power usage plus generation lost due to negative unit reliability (fewer hours per year of operation) resulting from each control alternative (kW-hrs/yr) compared to the pre-control baseline.

(9) - Environmental impacts summarize expected non-air effects and potential toxic air emissions resulting from control alternative compared to the pre-control baseline. Flyash unburned carbon content may increase with air-staging cyclones; carbon monoxide concentrations may increase an insignificant amount with air-staging cyclones. Excess unreacted ammonia (slip) expected from SNCR technology and the hypothetical application of SCR cases.

(10) - The inclusion of tail-end and low-dust SCR technologies in this table does not constitute agreement that it is technically feasible to install these technologies on Unit 1 at Milton R. Young Station. The estimated annual NOx removal and LTAC shown for a hypothetically-applied SCR system is based on assumptions that known or expected reasons for technical infeasibility for installation and operation and maintenance of the SCR equipment on this boiler are solvable. SCR technology is considered technically infeasible by Minnkota for application at MRYS per the October 2006 NO_X BACT Analysis Study report and subsequent submittals in response to comments by the NDDH, EPA, DOJ, and other parties, so this information for the hypothetical application of SCR alternatives is included for comparative purposes only. See Section 4.2.1.2.1 for details of Scenario A and Scenario B that assume replacement of SCR catalyst after a specified number of hours of unit operation.

MINNKOTA POWER COOPERATIVE, Inc. and SQUARE BUTTE ELECTRIC COOPERATIVE

RESPONSES TO NDDH REQUEST NOx BACT ANALYSIS STUDY MILTON R. YOUNG STATION UNIT 1 and UNIT 2 REGARDING SCR ECONOMIC FEASIBILITY

December 11, 2009

Revised February 2010 (refer to page 13 for Index of Revisions)

North Dakota Department of Health's Environmental Health Section, Division of Air Quality has requested[1] that Minnkota Power Cooperative Inc. ("Minnkota" or "MPC") provide more detailed and comprehensive cost data following their reviews of the Best Available Control Technology (BACT) Analysis Study – Supplemental reports[2] submitted on November 12, 2009 for control of nitrogen oxides (NO_X) emissions from existing Unit 1 and Unit 2 at Milton R. Young Station ("MRYS"). A detailed breakdown of capital costs and operation and maintenance costs for hypothetical applications of low-dust and tail end SCR alternatives, assuming that they are technically feasible to apply at MRYS as NDDH has recently advised[3], are attached. Responses to the use of steam from the main boilers for reheat of the flue gas are provided. A comparison of control costs from relevant recent BACT Determinations versus the estimated control costs of hypothetical applications of low-dust and tail end SCR technologies at MRYS included with the November 2009 Supplemental Reports is also provided.

Burns & McDonnell (B&McD) was retained by MPC as an independent consultant to perform the referenced NO_X BACT Analysis Study[4] of Minnkota's Unit 1 and Square Butte Electric Cooperative's Unit 2 at the Milton R. Young Station (MRYS) in accordance with the requirements of a Consent Decree (CD)[5]. The November 2009 NO_X BACT Analysis Study Supplemental Reports were generated in response to the NDDH's request[6] to see Steps 3 and

4 of the BACT analysis process[7] be performed and include low-dust and tail end SCR alternatives.

Detailed NOx BACT Analysis Study Supplemental reports' Capital and Operating & Maintenance Cost Summary:

NDDH Request: "A detailed breakdown of capital costs and operation and maintenance costs for the bulleted items on page 4-16 should be provided."[8]

BMcD Response:

The referenced "bulleted items on page 4-16" of the November 2009 NOx BACT Analysis Study Supplemental reports are intended to represent the major components (physical assets) that were identified as being required to install and operate low-dust and tail end SCRs if they were considered technically feasible for application at MRYS. Preliminary SCR Cost Estimates used as inputs to the November 2009 NO_X BACT Analysis Study Supplemental Reports were not developed based upon a direct match to each of the bulleted items included in the reports. Thus it is not possible to provide a cost breakdown in that format. In lieu of a breakout directly corresponding to the bulleted items, Burns & McDonnell has modified our cost estimate spreadsheets for the four "shared facilities" as well as the four "stand alone" hypothetical applications of SCR technologies analyzed, to reflect the cost tabulation format used in the "SCR Chapter" of the "EPA Air Pollution Control Cost Manual – Sixth Edition" (Section 4.2; Chapter 2).

Please see the attached "Shared Facilities Total Capital Investment" and "Stand Alone Total Capital Investment" cost estimate tables that follow the outline of Table 2.5 in the SCR Chapter of EPA's Control Cost Manual[9] for these hypothetical applications of SCR technologies analyzed. Note that this SCR Chapter of the EPA Control Cost Manual is intended for estimating costs of high dust SCRs, as it states on page 2-41 that "costs for the tail-end arrangement, however, cannot be estimated from this report because they are significantly higher

---

[7] See Reference number 8, October 1990.

[8] Ibid Reference number 1, November 25, 2009.

[9] Ibid Reference number 9, Section 4.2, Chapter 2, page 2-44, January 2002.

than the high-dust SCR systems due to flue gas heating requirements"[10]. The SCR Chapter of the Control Cost Manual also states that "the cost methodology is valid for a low-dust SCR system because the cost reductions are expected to be within the range of uncertainty for study-level costs"[11]. We also suggest that the SCR Cost Manual is not suitable for estimating the costs for the cold-side low-dust SCR arrangement analyzed in the Supplemental NOx BACT reports for MRYS because of the flue gas reheating required.

Also see attached tables of estimated "Shared Facilities Total Annual Costs" and "Stand Alone Total Annual Costs" that include the items described in pages 2-44 through 2-49 of the SCR Chapter of EPA's Control Cost Manual[12] for an SCR application. As previously mentioned, the equations in the SCR Cost Manual's cost methodology were not used for estimating annual costs of electrical power consumption, reagent usage, and catalyst replacements. Note that budgetary vendor quotes were the primary source of information used to calculate these estimated annual costs of the hypothetical applications of SCR technologies analyzed.

Use of Steam from the main boilers for reheat of flue gas (for low-dust and tail end SCR alternatives):

NDDH Request: "The use of steam from the main boilers for the flue gas reheat should also be addressed."

BMcD Response:

Natural gas-fired flue gas reheat is shown in the SCR Chapter of EPA's Control Cost Manual for an SCR application of a tail end SCR example[13], so the use of such reheat systems is not unique to Minnkota's study. MPC selected natural gas firing and rejected the use of steam for flue gas reheating for the evaluation of hypothetical applications of low-dust and tail end SCR technologies at MRYS. For the SCR cost estimate study by Burns & McDonnell, it was necessary to establish the scope conceptual design basis for estimating the costs associated with installation and operation and maintenance of the hypothetical applications of low-dust and tail

---

[10] Ibid Reference number 9, Section 4.2, Chapter 2, page 2-41, January 2002.
[11] Ibid Reference number 9, Section 4.2, Chapter 2, page 2-41, January 2002.
[12] Ibid Reference number 9, Section 4.2, Chapter 2, pages 2-44 – 2-49, January 2002.
[13] Ibid Reference number 9, Section 4.2, Chapter 2, page 2-21, January 2002.

end SCR technologies. Minnkota's selection of natural gas-fired flue gas reheating for these conceptual designs and cost estimates was made in order to avoid additional loss of unit electrical energy generation output capacity.

A preliminary high level conceptual review of the MRYS Unit 1 steam cycle was done by Minnkota to investigate the feasibility of using steam to achieve the estimated heat duty (was 31.1 but is now 54.5 million BTU/hr to raise flue gas temperature from ~~555°F~~ 535°F to 580°F for one reactor) required for the hypothetical application of low dust SCR technology. This preliminary review indicated that using steam for this service appeared to be feasible but would result in a unit electrical output capacity derate of ~~4-5 MW~~ 7 to 9 MW. This is because the high-temperature/high-pressure main steam extracted from the boiler for flue gas reheat system would not pass through any stages of the high/intermediate/low pressure steam turbines, so less net electrical energy would be produced.

The value of lost electrical generating capacity was not calculated, but the steady-state long term operation impact is believed to be approximately ~~50%~~ 90% or more of the total auxiliary electricity demand estimated in the November 2009 NO_X BACT Analysis Study Supplemental Reports' Table C.4-3[14] for the hypothetical application of SCR technologies at MRYS.

The preliminary concept assumed that main boiler steam (high pressure, high temperature, around 1000°F, 2500 psig) would be diverted from the steam turbine's inlet piping, and be routed for supply to the flue gas heating system. This would involve the heating steam supplied being condensed using heating coils inserted into the flue gas ductwork. The condensate liquid would then be returned to the boiler feedwater treatment system for reuse. The 7 to 9 MW (was 4-5 MW) Unit 1 derate for a hypothetical application of low-dust SCR technology does not include additional downtime due to tube leaks or other maintenance issues associated with the flue gas reheat steam system. Higher induced draft booster fan discharge pressure requirement for pressure drop is not included. Use of steam for cleaning the in-duct steam coils' exterior surfaces or the gas-to-gas heat exchanger online during operation using soot blowing is also not included in this estimate of the potential unit derate. The time required to modify the main steam

---

[14] Ibid Reference 2, page 4-27.

piping and other steam turbine and boiler feedwater treatment system components in the steam cycle power generation and balance-of-plant systems and boiler flue gas systems to accommodate such suggested changes would be lengthy. The duration of an outage to implement such modifications, and value of lost electrical generating capacity, would be significant.

A similar preliminary high level conceptual review of the MRYS Unit 2's steam cycle to investigate the feasibility of using steam to achieve the estimated heat duty (2 reactors, 48.1 MMBTU/hr each to raise flue gas temperature from 535°F to 580°F) required for a hypothetical application of low-dust SCR technology was not performed. Although sizing was not evaluated for MRYS Unit 2, using a scaling factor (4-5 MW times the ratio of 96.2 divided by 31.1 MMBTU/hr heat duty values~~477 MW divided by 257 MW nameplate capacity ratings~~) to estimate Unit 2's derate compared with Unit 1's estimated derate could be applied for an approximation. This would yield a potential Unit 2 electrical generating output capacity derate on the order of magnitude of ~~8-10 MW~~ 12.4 to 15.5 MW for a hypothetical application of low-dust SCR technology. Similar impacts and issues as described for Unit 1 would be expected for Unit 2.

A similar preliminary high level conceptual review of the MRYS Unit 1's steam cycle to investigate the feasibility of using steam to achieve the estimated heat duty (1 reactor, 60.3 MMBTU/hr each to raise flue gas temperature from 520°F to 563°F) required for a hypothetical application of tail end SCR technology was not performed. Although sizing was not evaluated for this case, using a scaling factor (ratio of 60.3 divided by 31.1 heat duties) to estimate Unit 1's derate compared with Unit 1's estimated derate for a hypothetical application of low-dust SCR technology could be applied for an approximation. This would yield a potential Unit 1 electrical generating output capacity derate on the order of magnitude of 8 to 10 MW for a hypothetical application of tail end SCR technology. Similar impacts and issues as previously described for Unit 1 would be expected.

A similar preliminary high level conceptual review of the MRYS Unit 2's steam cycle to investigate the feasibility of using steam to achieve the estimated heat duty (2 reactors, 50.8

MMBTU/hr each to raise flue gas temperature from 520°F to 563°F) required for a hypothetical application of tail end SCR technology was not performed. Although sizing was not evaluated for MRYS Unit 2, using a scaling factor (ratio of 101.6 divided by 31.1 heat duties) to estimate Unit 2's derate compared with Unit 1's estimated derate could be applied for an approximation. This would yield a potential Unit 2 electrical generating output capacity derate on the order of magnitude of 13 to 16 MW for a hypothetical application of tail end SCR technology. Similar impacts and issues as described for Unit 1 would be expected for Unit 2.

These estimates of lost electrical generation outputs come from boiler main steam usage, larger induced draft fan power requirements, and potential additional downtime associated with the flue gas reheating systems. Because the MRYS units' electrical energy generation output capacity is limited by the steam energy production capacity of each boiler ("boiler limited"), there is not "free capacity margin" available to offset the megawatt losses. Minnkota also cannot increase boiler hourly heat inputs (coal firing rates) in order to compensate for the decrease in output because the increased emissions from higher firing rates are not permitted.

Additional arguments that support the decision to select natural gas firing and reject the use of steam for flue gas reheating involving hypothetical applications of low-dust and tail end SCR technologies at MRYS:

- Minnkota's previous experience with the use of steam for Unit 2's flue gas desulfurization system absorber outlet flue gas reheat (for stack plume buoyancy) was not positive and the technique was abandoned in favor of reheat via scrubber flue gas bypass. The Consent Decree does not allow Minnkota to continue the use of unscrubbed flue gas for reheating the stack gas[15].
- Boiler-turbine steam systems are complex and sensitive to steam inputs, extractions, and outlet conditions. There was insufficient time available during the SCR cost estimate study to perform a comprehensive analysis of potential performance impacts from the modifications related to the use of steam for flue gas reheat.
- High pressure/high temperature steam piping is expensive to procure and install, and requires special design to accommodate thermal growth and significant weight and

---

[15] Ibid Reference number 5, April 24, 2006.

dynamic loads without overstress. There was insufficient time available during the SCR cost estimate study to perform a comprehensive analysis of potential hanger supports, pipe sizing and routing from the main steam source to the multiple points of use and return of condensate to the boiler plant.

- The deposits removed during cleaning of the in-duct steam coils fouled by particulate, aerosols, and ash products emitted from the boilers and also removed from the gas-gas heat exchanger upstream of the flue gas reheater will be entrained in the flue gas stream entering the SCR reactor. This will require a "large particle ash screen" that creates more pressure drop than the direct-fired duct burner.

Comparison of Average and Incremental Control Costs for MRYS NOx BACT (for low-dust and tail end SCR alternatives) versus recent BACT determinations:

NDDH Request: "It should be documented that the costs of SCR at the M.R. Young Station are significantly beyond the range of recent costs normally associated with BACT for coal-fired power plants (or BACT control costs in general) for the control of nitrogen oxides (NSR Manual Chapter B, Section IV.D.2.C)."

BMcD Response:

A review of available information on "costs normally associated with BACT" for control of NOx emissions from coal-fired power plants indicates that very little documentation is published. Although both the EPA's RACT BACT LAER Clearinghouse (RBLC) [http://cfpub.epa.gov/rblc/htm/bl02.cfm] and the EPA's "National Coal-Fired Utility Projects Spreadsheet" [available via http://www.epa.gov/ttn/catc/products.html#misc] include an assigned database field for entry of "Control Cost Effectiveness" in units of $/ton, neither of these sources contains much information. The assigned field where the data should be entered is blank in the vast majority of cases entered in these databases.

This dearth of data on BACT cost effectiveness was encountered by EPA Region 8 during its preparation of the "Response to Public Comments" for the Draft PSD Permit for Deseret Power Electric Cooperative's proposed 110 MW waste coal fired unit addition to the Bonanza Power Plant[16]. In seeking to defend the cost basis for its rejection of a control technology as BACT, EPA Region 8 was able to identify only 13 cases (total for all pollutants) in which control cost effectiveness data were identified in recent permit actions involving BACT.

Burns & McDonnell reviewed the cases identified by EPA Region 8 in their response for the Deseret BACT case to determine if any data on "the cost associated with BACT" was available for cases involving NOx control for coal-fired boilers. Of the 13 cases for all pollutants identified by EPA Region 8, only one case involved the rejection of the "top" NOx control

---

[16] See Reference number 10, pages 29-33.

technology as BACT due to what was identified as "excessive cost". This was the case of MDU's proposed Gascoyne project in North Dakota. The inability of EPA Region 8 to identify more cases in which the permit record clearly establishes the level of NOx control costs illustrates the difficulty of this task.

Burns & McDonnell was able to identify only two other cases, both also in North Dakota, in which the permit record shows that the "top" NOx control technology for a coal-fired boiler was rejected as having an excessive "control cost effectiveness". The relevant data for these cases is tabulated below, and compared to similar information as stated in the Supplemental NO_X BACT reports prepared for MRYS Units 1 and 2.

Previous Coal-Fired Boiler NO_X BACT Determinations Based on Cost Effectiveness

State	Utility	Plant Name	Technology Considered Technically Feasible but Rejected as BACT by State Agency	Average Control Cost of Rejected Technology	Average Control Cost of Technology Accepted as BACT	Technology Recommended as BACT
ND	MDU	Gascoyne	SCR	$7545/ton	$2926/ton	SNCR
ND	South Heart Coal LLC	South Heart	SCR	$7640/ton	$1690/ton	SNCR
ND	GRE	Spiritwood	SCR	$7640/ton	$1843/ton	SNCR

As shown in the table above, for coal-fired boilers the "average cost effectiveness of BACT for NOx" as established in previous permit actions ranges from $1690/ton to $2926/ton. By comparison, the estimated cost for NOx control using SCR, which was rejected as BACT due to excessive costs in these previous cases, ranged from 2.6 to 4.5 times the control cost of the technology established as BACT using the "top down" process.

Control Cost Data from MRYS Units 1 & 2 Supplemental NOx BACT Reports

"Top" Technology Recommended to be Rejected as BACT	Average Control Cost of "Top" Technology	Average Control Cost of Technology Recommended as BACT	Technology Recommended as BACT
MRYS Unit 1 Low-Dust or Tail End SCR with ASOFA	\$3,586/ton to \$5,969/ton	\$1,265/ton	MRYS Unit 1 SNCR with ASOFA
MRYS Unit 2 Low-Dust or Tail End SCR with ASOFA	\$3,859/ton to \$6,597/ton	\$1,240/ton	MRYS Unit 2 SNCR with ASOFA

In the case of MRYS Units 1 and 2, and taking the range of control costs for SCR (TESCR and LDSCR) with ASOFA as presented in the Supplemental NO_X BACT reports (shown above), the ratio between the cost of the technology proposed for rejection on a cost basis to the cost of the technology proposed as BACT for the MRYS units is quite similar to that seen in previous permit actions. For Unit 1, the cost ratio ranges from 2.8 to 4.7. For Unit 2, the cost ratio ranges from 3.1 to 5.3. Thus it appears that the same rationale that was used to reject SCR technology as being "excessively costly on a \$/ton control cost basis" in the case of these other three North Dakota BACT determinations should also apply to the case of MRYS.

(8) Owner's Costs - Other	$ 13,632,335	$ 24,182,077	$ 16,920,540	$ 29,632,862	Note 25
TOTAL CAPITAL INVESTMENT	**$183,273,957**	**$317,428,728**	**$240,817,176**	**$411,062,963**	Note 26

Shared Facilities (SF) represents estimated costs if SCR equipment is retrofitted to both boilers concurrently. This table follows outline of Table 2.5 of EPA OAQPS SCR Cost Manual, EPA/452/B-02-001 Section 4.2 NOx Controls Post Combustion, page 2-44.

Note 1: Includes costs for SCR equipment including initial catalyst, flue gas heat recovery equipment, and flue gas reheat burner equipment as well mechanical setting of this equipment.

Note 2: Does not include spare catalyst in purchased SCR equipment costs.

Note 3: Includes service air and sootblower air compressors, induced draft booster fan(s) and dampers, urea-to-ammonia conversion ~~flue gas reheat~~ equipment with natural gas-firing burners and fan(s), SCR bypass ducts and isolation dampers, interconnecting ductwork, equipment for active coal yard storage modifications, and catalyst standby heating auxiliary equipment costs as well as mechanical setting of this equipment. (Revised February 2010)

Note 4: Instrumentation and controls are included in Electrical Construction costs (see Note 10).

Note 5: Sales taxes for engineered equipment and permanent materials is not included; Taxes are included for consumable materials.

Note 6: Delivery expenses are included in equipment costs.

Note 7: Sum of SCR, Auxiliaries/Balance of Plant, and Instruments/Controls equipment costs; taxes and freight.

Note 8: Includes site excavation, structural steel, concrete, and architectural construction costs. Includes SCR bypass ducts and isolation dampers, and interconnecting ductwork construction costs.

Note 9: Estimated separately as shown in Table 4.5 SF in Supplemental BACT Control and Cost Effectiveness Analysis.

Note 10: Instrumentation and Controls, additional plant electrical distribution equipment are included in Electrical construction costs.

Note 11: Mechanical/Piping includes material and installation of all piping not provided with engineered equipment.

Note 12: Insulation includes ductwork and piping insulation.

Note 13: Painting included in structural and architectural construction costs.

Note 14: Sum of Direct Capital Construction Costs.

Note 15: Sum of Total Purchased Capital Equipment and Total Direct Capital Construction Costs; considered to be equivalent to "A" in EPA OAQPS SCR Cost Manual Table 2.5.

Note 16: Sum of Engineering and Field Support Costs.

Note 17: Sum of Construction Management and Construction Indirects.

Note 18: Startup Costs include costs for startup engineering support.

Note 19: Scope contingency is to account for potential changes in the project scope resulting from engineering, equipment, and/or construction work which were not identified or included.

Note 20: Pricing contingency is to account for potential changes in project costs resulting from wages, productivities, equipment and/or materials costs being higher than anticipated. Note: this does not intend to cover pricing increases over time, i.e. Escalation. Considered to be equivalent to "C" in EPA OAQPS SCR Cost Manual Table 2.5.

Note 21: Sum of Indirect Capital Installation Costs; considered to be equivalent to "D", Total Plant Costs in EPA OAQPS SCR Cost Manual Table 2.5.

Note 22: Escalation is a result of anticipated increases in costs that are due to higher costs over time.

Note 23: Interest During Construction (or Allowance for Funds During Construction) are considered to be equivalent to "E" in EPA OAQPS SCR Cost Manual Table 2.5.

Note 24: Natural gas pipeline construction cost was assumed as an owner cost.

Note 25: Other Owner Costs include Owner personnel, insurance, pilot testing, Owner Contingency and Spare Parts.

Note 26: Total Capital Investment (TCI) is equivalent to Installed Capital Cost for Low-Dust and Tail End SCRs in the November 2009 NOx BACT Supplemental Analysis Table 4-5SF, page 4-18. The installed capital cost of the Urea Storage Tanks and Building, and Advanced Separated Overfire Air (ASOFA) system, are not included in these numbers. See Table 4-5SF.

(8) Owner's Costs - Other	$ 23,114,224	$ 27,867,439	$ 26,204,034	$ 33,248,637	Note 25
TOTAL CAPITAL INVESTMENT	**$236,658,008**	**$342,502,146**	**$294,586,374**	**$436,345,697**	Note 26

Stand Alone (SA) represents estimated costs if SCR equipment is retrofitted to both boilers independently. This table follows outline of Table 2.5 of EPA OAQPS SCR Cost Manual, EPA/452/B-02-001 Section 4.2 NOx Controls Post Combustion, page 2-44.

Note 1: Includes costs for SCR equipment including initial catalyst, flue gas heat recovery equipment, and flue gas reheat burner equipment as well mechanical setting of this equipment.

Note 2: Does not include spare catalyst in purchased SCR equipment costs.

Note 3: Includes service air and sootblower air compressors, induced draft booster fan(s) and dampers, urea-to-ammonia conversion ~~flue gas reheat~~ equipment with natural gas-firing burners and fan(s), SCR bypass ducts and isolation dampers, interconnecting ductwork, equipment for active coal yard storage modifications, and catalyst standby heating auxiliary equipment costs as well as mechanical setting of this equipment. (Revised February 2010)

Note 4: Instrumentation and controls are included in Electrical Construction costs (see Note 10).

Note 5: Sales taxes for engineered equipment and permanent materials is not included; Taxes are included for consumable materials.

Note 6: Delivery expenses are included in equipment costs.

Note 7: Sum of SCR, Auxiliaries/Balance of Plant, and Instruments/Controls equipment costs; taxes and freight.

Note 8: Includes site excavation, structural steel, concrete, and architectural construction costs. Includes SCR bypass ducts and isolation dampers, and interconnecting ductwork construction costs.

Note 9: Estimated separately as shown in Table 4.5 SA in Supplemental BACT Control and Cost Effectiveness Analysis.

Note 10: Instrumentation and Controls, additional plant electrical distribution equipment are included in Electrical construction costs.

Note 11: Mechanical/Piping includes material and installation of all piping not provided with engineered equipment.

Note 12: Insulation includes ductwork and piping insulation.

Note 13: Painting included in structural and architectural construction costs.

Note 14: Sum of Direct Capital Construction Costs.

Note 15: Sum of Total Purchased Capital Equipment and Total Direct Capital Construction Costs; considered to be equivalent to "A" in EPA OAQPS SCR Cost Manual Table 2.5.

Note 16: Sum of Engineering and Field Support Costs.

Note 17: Sum of Construction Management and Construction Indirects.

Note 18: Startup Costs include costs for startup engineering support.

Note 19: Scope contingency is to account for potential changes in the project scope resulting from engineering, equipment, and/or construction work which were not identified or included.

Note 20: Pricing contingency is to account for potential changes in project costs resulting from wages, productivities, equipment and/or materials costs being higher than anticipated. Note: this does not intend to cover pricing increases over time, i.e. Escalation. Considered to be equivalent to "C" in EPA OAQPS SCR Cost Manual Table 2.5.

Note 21: Sum of Indirect Capital Installation Costs; considered to be equivalent to "D", Total Plant Costs in EPA OAQPS SCR Cost Manual Table 2.5.

Note 22: Escalation is a result of anticipated increases in costs that are due to higher costs over time.

Note 23: Interest During Construction (or Allowance for Funds During Construction) are considered to be equivalent to "E" in EPA OAQPS SCR Cost Manual Table 2.5.

Note 24: Natural gas pipeline construction cost was assumed as an owner cost.

Note 25: Other Owner Costs include Owner personnel, insurance, pilot testing, Owner Contingency and Spare Parts.

Note 26: Total Capital Investment (TCI) is equivalent to Installed Capital Cost for Low-Dust and Tail End SCRs in the November 2009 NOx BACT Supplemental Analysis Table 4-5SA, page 4-17. The installed capital cost of the Urea Storage Tanks and Building, and Advanced Separated Overfire Air (ASOFA) system, are not included in these numbers. See Table 4-5SA.

Estimates of Total Annual Costs for
Low Dust and Tail End Selective Catalytic Reduction Alternatives
Best Available Control Technology - Supplemental Analysis

Shared Facilities

DIRECT ANNUAL COSTS	**Low Dust U1**	**Low Dust U2**	**Tail End U1**	**Tail End U2**	**Notes**
(1) Annual Maintenance Costs	$ 4,189,181	$ 7,514,611	$ 5,444,530	$ 9,608,381	Note 1
(2) Annual Reagent Costs					Note 2
Scenario A	$ 2,710,313	$ 4,171,528	$ 2,709,417	$ 4,170,150	
Scenario B	$ 2,725,539	$ 4,204,613	$ 2,724,643	$ 4,204,613	
(3) Annual Electricity Costs					Note 3
Scenario A	$ 5,929,642	$ 9,730,376	$ 6,011,088	$ 9,740,159	
Scenario B	$ 11,939,901	$ 24,539,279	$ 11,982,549	$ 25,083,883	
(4) Annual Water Costs					Note 4
(5) Catalyst Replacement Costs					Note 5
Scenario A	$ 709,951	$ 958,131	$ 709,951	$ 963,350	Note 6
Scenario B	$ 4,387,500	$ 10,260,000	$ 4,387,500	$ 10,260,000	Note 7
(6) Natural Gas for F.G. Reheating & Urea-to-Ammonia Conversion sys.					Note 8
Scenario A	$ 2,136,238	$ 6,064,108	$ 3,931,511	$ 6,416,128	
Scenario B	$ 1,944,698	$ 5,296,499	$ 3,580,852	$ 5,574,558	Note 9
(7) Operating labor for SCR equipment and urea-to-ammonia eqpmnt					Note 10
DIRECT Annual COSTS - TOTAL					Note 11
Scenario A	$ 15,675,326	$ 28,438,754	$ 18,806,498	$ 30,898,167	
Scenario B	$ 25,186,819	$ 51,815,002	$ 28,120,074	$ 54,731,434	
INDIRECT Annual COSTS					
(8) Annual Costs from Capital Recovery	$ 12,174,396	$ 21,838,601	$ 15,822,632	$ 27,923,414	Note 12
(9) Administrative overhead, insurance and property taxes for SCRs and aux.					Note 13
INDIRECT Annual COSTS - TOTAL	$ 12,174,396	$ 21,838,601	$ 15,822,632	$ 27,923,414	
TOTAL ANNUAL COSTS					Note 14
Scenario A	$ 27,849,722	$ 50,277,355	$ 34,629,130	$ 58,821,580	
Scenario B	$ 37,361,215	$ 73,653,603	$ 43,942,706	$ 82,654,848	
LEVELIZED TOTAL ANNUALIZED COSTS					Note 15
Scenario A	$ 31,748,616	$ 57,350,872	$ 39,306,834	$ 66,506,822	
Scenario B	$ 43,625,884	$ 86,541,448	$ 50,936,958	$ 96,268,092	

Shared Facilities (SF) represents estimated costs if SCR equipment is retrofitted to both boilers concurrently.
This table includes values that are identified in the EPA OAQPS SCR Cost Manual, EPA/452/B-02-001 Section 4.2 NOx Controls Post Combustion, page 2-44 through 2-49 but use calculated and vendor-quoted values instead of the formulas provided in the OAQPS manual
Total Annual Costs consist of direct costs, indirect costs, and recovery credits (if any). Direct Annual Costs and variable and semi-variable costs that are proportional to the quantity of flue gas processed by the control system. Indirect Annual Costs are fixed costs incurred independent of control operation, and include capital recovery costs, insurance, administrative charges, and overhead (payroll and plant).
Note 1: Annual maintenance was assumed to be 3% of installed capital cost of the SCR equipment and auxiliary equipment related to the SCR systems, not including catalyst replacement costs. Maint. costs for ASOFA are included.
Note 2: Annual reagent costs are for "Scenario A" and "Scenario B" operation and related chemical usage based on receiving 50% aqueous urea solution, assumed to be $379.29 per ton in 2006$.
Note 3: Annual electricity costs are for "Scenario A" and "Scenario B" operation and related electricity consumption and lost generation, assumed to be $35/MW-hr in 2006$. See Tables C.4-1 through C.4-4 in the November 2009 NOx BACT Analysis Study Supplemental Reports for details.
Note 4: Annual water costs were not calculated, but may be more than zero, if concentrated liquid urea liquor (70% concentration) is purchased, which must be diluted to 50% concentration for storage.
Note 5: Annual catalyst replacement costs are for "Scenario A" and "Scenario B" operation, and are assumed to be based on $7,500 per cubic meter in 2006$.
Note 6: Annual catalyst replacement costs for "Scenario A" are assumed to be based one layer per reactor every two years (approx. 16,000 operating hours), and follows the EPA OAQPS SCR Cost Manual for annualizing the purchase cost using Equations 2.51 and 2.52 on page 2-47 and Equation 2.53 on page 2-48 assuming 6% per year annual interest rate. Tail end SCRs were assumed to have 10 layers replaced during the 20-year economic evaluation period, and 12 layers for Low-dust SCRs, but the annual catalyst replacement costs for U2 used in the November 2009 NOx BACT Analysis Study Supplemental Report underestimate the cost per layer due to assuming regular depth layers instead of deep layers recommended by vendor.
Note 7: Annual catalyst replacement costs for "Scenario B" are assumed to be based three layers per reactor every year (approx. 2,667 operating hours) for U1 and four layers per reactor per year (approx. 2,000 operating hours) for U2. There were no adjustments for annualizing the purchase cost (Equations 2.51 and 2.52 on page 2-47 and Equation 2.53 on page 2-48 of the EPA OAQPS SCR Cost Manual were not used). U1 Low-dust and Tail end SCRs were assumed to have 60 layers replaced during the 20-year economic evaluation period, and 80 layers for U2's Tail end SCRs.
Note 8: Annual costs of natural gas firing for flue gas reheating and urea-to-ammonia conversion system operation for "Scenario A" and "Scenario B" are assumed to be based on $7.98 per million BTU in 2006$.
Note 9: Annual costs of natural gas firing for "Scenario B" are lower than "Scenario A" due to fewer annual hours of operation resulting from additional catalyst replacements.
Note 10: Annual costs of operating labor for SCR equipment, flue gas reheating, and urea-to-ammonia systems were assumed to be zero, but this may underestimate actual requirements.
Note 11: Total Direct Annual Costs are the sum of maintenance, reagent, electricity, catalyst replacements, and natural gas for Scenario A and Scenario B operations. This may underestimate actual requirements.
Note 12: Annual Costs from capital recovery are the same for Scenario A and Scenario B operations. See Appendix C in the 2006 NOx BACT Analysis Study reports for details. The capital recovery factor used to calculate the annual costs is 0.087185. Capital recovery costs for ASOFA are included.
Note 13: Annual costs of increases in administrative overhead, insurance premiums, and property taxes for SCR equipment and related auxiliaries were assumed to be zero, but this may underestimate actual requirements.
Note 14: Total Annual Costs are the sum of increases in Direct Costs and Indirect Costs for SCR equipment and related auxiliaries. These values may underestimate actual requirements.
Note 15: Levelized Total Annualized Costs are TDC multiplied by the levelization factor (1.24873) plus the Total Indirect Annual Costs (capital recovery). See Appendix C in the 2006 NOx BACT Analysis Study Reports for details. These values may underestimate actual requirements.

These numbers are the same Levelized Total Annualized Costs for Low-Dust and Tail End SCRs in the November 2009 NOx BACT Supplemental Analysis Tables 4-6SF, 4-7SF, 4-8SF, and 4-9SF. The capital recovery costs of the Urea Storage Tanks and Building, and Advanced Separated Overfire Air (ASOFA) system, based on the installed capital costs shown in Tables 4-4SF and 4-5SF, are included in these numbers.

Scenario A	$ 36,871,522	$ 59,880,950	$ 44,464,651	$ 69,056,347	
Scenario B	$ 50,575,055	$ 89,071,526	$ 56,094,775	$ 98,817,617	

Stand Alone (SA) represents estimated costs if SCR equipment is retrofitted to both boilers independently.

This table includes values that are identified in the EPA OAQPS SCR Cost Manual, EPA/452/B-02-001 Section 4.2 NOx Controls Post Combustion, page 2-44 through 2-49 but use calculated and vendor-quoted values instead of the formulas provided in the OAQPS manual

Total Annual Costs consist of direct costs, indirect costs, and recovery credits (if any). Direct Annual Costs and variable and semi-variable costs that are proportional to the quantity of flue gas processed by the control system. Indirect Annual Costs are fixed costs incurred independent of control operation, and include capital recovery costs, insurance, administrative charges, and overhead (payroll and plant).

Note 1: Annual maintenance was assumed to be 3% of installed capital cost of the SCR equipment and auxiliary equipment related to the SCR systems, not including catalyst replacement costs. Maint. costs for ASOFA are included.

Note 2: Annual reagent costs are for "Scenario A" and "Scenario B" operation and related chemical usage based on receiving 50% aqueous urea solution, assumed to be $379.29 per ton in 2006$.

Note 3: Annual electricity costs are for "Scenario A" and "Scenario B" operation and related electricity consumption and lost generation, assumed to be $35/MW-hr in 2006$. See Tables C.4-1 through C.4-4 in the November 2009 NOx BACT Analysis Study Supplemental Reports for details.

Note 4: Annual water costs were not calculated, but may be more than zero, if concentrated liquid urea liquor (70% concentration) is purchased, which must be diluted to 50% concentration for storage.

Note 5: Annual catalyst replacement costs are for "Scenario A" and "Scenario B" operation, and are assumed to be based on $7,500 per cubic meter in 2006$.

Note 6: Annual catalyst replacement costs for "Scenario A" are assumed to be based one layer per reactor every two years (approx. 16,000 operating hours), and follows the EPA OAQPS SCR Cost Manual for annualizing the purchase cost using Equations 2.51 and 2.52 on page 2-47 and Equation 2.53 on page 2-48 assuming 6% per year annual interest rate. Tail end SCRs were assumed to have 10 layers replaced during the 20-year economic evaluation period, and 12 layers for Low-dust SCRs, but the annual catalyst replacement costs for U2 used in the November 2009 NOx BACT Analysis Study Supplemental Report underestimate the cost per layer due to assuming regular depth layers instead of deep layers recommended by vendor.

Note 7: Annual catalyst replacement costs for "Scenario B" are assumed to be based three layers per reactor every year (approx. 2,667 operating hours) for U1 and four layers per reactor per year (approx. 2,000 operating hours) for U2. There were no adjustments for annualizing the purchase cost (Equations 2.51 and 2.52 on page 2-47 and Equation 2.53 on page 2-48 of the EPA OAQPS SCR Cost Manual were not used). U1 Low-dust and Tail end SCRs were assumed to have 60 layers replaced during the 20-year economic evaluation period, and 80 layers for U2's Tail end SCRs.

Note 8: Annual costs of natural gas firing for flue gas reheating and urea-to-ammonia conversion system operation for "Scenario A" and "Scenario B" are assumed to be based on $7.98 per million BTU in 2006$.

Note 9: Annual costs of natural gas firing for "Scenario B" are lower than "Scenario A" due to fewer annual hours of operation resulting from additional catalyst replacements.

Note 10: Annual costs of operating labor for SCR equipment, flue gas reheating, and urea-to-ammonia systems were assumed to be zero, but this may underestimate actual requirements.

Note 11: Total Direct Annual Costs are the sum of maintenance, reagent, electricity, catalyst replacements, and natural gas for Scenario A and Scenario B operations. This may underestimate actual requirements.

Note 12: Annual Costs from capital recovery are the same for Scenario A and Scenario B operations. See Appendix C in the 2006 NOx BACT Analysis Study reports for details. The capital recovery factor used to calculate the annual costs is 0.087185. Capital recovery costs for ASOFA are included.

Note 13: Annual costs of increases in administrative overhead, insurance premiums, and property taxes for SCR equipment and related auxiliaries were assumed to be zero, but this may underestimate actual requirements.

Note 14: Total Annual Costs are the sum of increases in Direct Costs and Indirect Costs for SCR equipment and related auxiliaries. These values may underestimate actual requirements.

Note 15: Levelized Total Annualized Costs are TDC multiplied by the levelization factor (1.24873) plus the Total Indirect Annual Costs (capital recovery). See Appendix C in the 2006 NOx BACT Analysis Study Reports for details. These values may underestimate actual requirements.

These numbers are the same Levelized Total Annualized Costs for Low-Dust and Tail End SCRs in the November 2009 NOx BACT Supplemental Analysis Tables 4-6SA, 4-7SA, 4-8SA, and 4-9SA. The capital recovery costs of the Urea Storage Tanks and Building, and Advanced Separated Overfire Air (ASOFA) system, based on the installed capital costs shown in Tables 4-4SA and 4-5SA, are included in these numbers.

MINNKOTA POWER COOPERATIVE, Inc. and SQUARE BUTTE ELECTRIC COOPERATIVE

FOLLOWUP RESPONSES TO PRESENTATION and NDDH REQUEST FOR ADDITIONAL INFORMATION SUPPLEMENTAL NOx BACT ANALYSIS STUDY MILTON R. YOUNG STATION UNIT 1 and UNIT 2 REGARDING SCR ECONOMIC FEASIBILITY

February 11, 2010

North Dakota Department of Health's Environmental Health Section, Division of Air Quality has requested[1] that Minnkota Power Cooperative Inc. ("Minnkota" or "MPC") provide additional information clarifying the written response submitted December 11, 2009[2] that provided detailed and comprehensive cost data following the NDDH's and U.S. EPA's reviews of the Best Available Control Technology (BACT) Analysis Study – Supplemental Reports[3] submitted on November 12, 2009 for control of nitrogen oxides (NO_X) emissions from existing Unit 1 and Unit 2 at Milton R. Young Station (MRYS).

Burns & McDonnell (B&McD) was retained by MPC as an independent consultant to perform the referenced 2006 NO_X BACT Analysis Study[4] of Minnkota's Unit 1 and Square Butte Electric Cooperative's Unit 2 at the Milton R. Young Station in accordance with the requirements of a Consent Decree (CD)[5]. Burns & McDonnell also performed the November 2009 Supplemental NO_X BACT Analysis Study and generated the referenced reports for each MRYS boiler in response to the NDDH's request[6] to see Steps 3 and 4 of the BACT analysis process[7] include low-dust and tail end SCR alternatives, assuming that they are technically feasible to apply at MRYS as NDDH has recently advised[8].

Information supplementing the previously-provided detailed breakdown of capital costs and operation and maintenance costs for hypothetical applications of low-dust and tail end SCR alternatives, and their subsequent presentation to NDDH, are attached.

---

[8] Ibid Reference number 6, July 15, 2009. SCR technology is considered technically infeasible by Minnkota for application at MRYS per the October 2006 NOx BACT Analysis Study report and subsequent submittals in response to comments by the NDDH, EPA, DOJ, and other parties, including the November 2009 Supplemental NOx BACT Analysis Study reports.

NOx BACT Analysis Study Supplemental Reports:

NDDH Request #1: How were the SCR reactors sized and the catalyst volume determined and what target NOx control efficiency was used to size the catalyst? How was the cost of the catalyst determined?

BMcD Response:

The same SCR system supplier that is providing the low-dust SCR equipment for the WE Energies South Oak Creek project in Wisconsin was asked to provide a budgetary equipment proposal for both low-dust and tail end SCR arrangements for each unit at MRYS. A lignite coal analysis (proximate, ultimate, and coal ash) and process design basis (boiler fuel heat input rates, excess air percentages, flue gas volumetric flows, temperatures and gas species contents) were included with the request. An assumed inlet and outlet NOx concentration was also provided, with a nominal 85% reduction from 0.5 lb/mmBtu requested. This SCR system supplier sized the SCR reactor, the SCR gas-to-gas heat exchange equipment (SCR GGH), and related ductwork. The initial catalyst charge for each reactor was included in the lump-sum equipment price proposal. The SCR system supplier did not disclose the specific volume of catalyst to be provided nor the specific manufacturer or type of catalyst (i.e. honeycomb, plate, etc.). Due to the proprietary nature of this SCR conceptual design and budgetary equipment pricing effort, this work was performed by the SCR system supplier with the understanding that it was confidential. Refer to Burns & McDonnell’s response to NDDH Request #7 for additional information.

Two SCR catalyst suppliers provided budgetary replacement catalyst quotes, including catalyst volume, catalyst pitch, catalyst type, and arrangement of catalyst modules, based on preliminary process design provided by an SCR process design consultant. The design used for these catalyst supplier proposals was based on 90% overall NOx reduction across the SCR system. The catalyst suppliers also provided cost proposals for the replacement catalyst. One supplier provided a cost of replacement catalysts in terms of $\$/m^3$. Due to the proprietary nature of this SCR reactor sizing and budgetary catalyst pricing effort, this work was performed by the SCR catalyst suppliers with the understanding that it was confidential. Refer to Burns & McDonnell’s response to NDDH Request #7 for additional information.

NDDH Request #2: Anhydrous ammonia appears to be a less expensive reagent than urea for the SCR system due to local availability. A justification must be supplied for electing urea over anhydrous ammonia.

BMcD Response:

Aqueous urea solution was selected because of health and safety issues related to the use of ammonia, including site constraints involving over-the-road transport, on-site unloading and storage. MRYS does not have rail access, and is adjacent to a lake used for condenser cooling water and process water supplies. Public access to the lake is allowed. Anhydrous ammonia and aqueous ammonia are classified as hazardous chemicals per Clean Air Act Section 112 (r). This requires extensive emergency planning. Transport and handling of ammonia is restricted by the United States Department of Homeland Security and the Department of Transportation through the Rail Security Act. The U.S. EPA has determined that a toxic radius of a spill to be between 5 and 7 miles for anhydrous ammonia and 1 to 2 miles for aqueous ammonia[9].

NDDH Request #3: Support must be provided for the catalyst cleaning/replacement outage periods. This should include an explanation of the method used to estimate the outage time and clarification whether the outage time includes the regular outage period.

BMcD Response:

Burns & McDonnell and Minnkota queried SCR catalyst suppliers, process design consultants, utility construction and maintenance contractors, and utility personnel at U.S. coal-fired plants with operating SCRs to provide input into the estimation of time associated with catalyst installation into the empty (spare) layer of the reactor, and to remove dirty catalyst and install fresh catalyst in its place. The responses indicated that there is a broad range of experiences based on limited amounts of user and vendor data on this issue. The range of experience is due to the site-specific conditions and design-specific features of the reactor catalyst access doors' locations and sizes, module arrangement, hoisting equipment, staging areas and platforms, labor availability and familiarity. The general lack of data is due to the relative newness of many SCR installations currently operating at coal-fired powerplants in the United States that have not accumulated significant operating time and so have not required significant numbers of catalyst changeouts.

Catalyst replacement activities by current coal-fired powerplant users are typically scheduled during major boiler outages that are 18-36 months apart. The SCR catalyst changeout is usually not a schedule-critical activity during such outages. The catalyst changeout time required depends on how many modules are involved, and whether a single shift of personnel or multiple shifts per day are engaged in the work.

For the hypothetical application of low-dust and tail end SCR technologies at MRYS, most of the catalyst changeouts were assumed to coincide with boiler fireside cleaning outages, which are historically approximately 4 days in duration, three or four times per year, depending on the boiler involved. Because of the use of high pressure water to remove boiler deposits during these cleanings, the air exhausted from the boilers through the flue gas ductwork to the chimneys during these times contains moisture and particulate.

---

[9] See Reference 8.

Catalyst vendors have advised that this air stream is not suitable for passing through an SCR reactor filled with catalyst. This will require an SCR reactor bypass to be provided for use during these outages.

Before catalyst changeout operations can begin, the large volume of catalyst and supporting structural steel must be cooled down sufficiently to allow personnel to safely enter the reactor to gain access to remove any ash accumulations. The means and equipment required to remove the catalyst depends on the specific reactor design and module arrangements. The specific time and equipment requirements for catalyst changeouts are normally developed after the specific reactor and module details are established.

The SCR Cost Estimate study assumed that reactor isolation dampers and reactor maintenance bypass ductwork dampers would be required to avoid contamination of the catalyst by the air/water/particulate stream, and allow the reactors to be cooled while being isolated from the normal flue gas path to the chimney. The time estimated for catalyst installation into the empty (spare) layer of the reactor was 16 shifts, which, assuming two shifts per day, would be 8 days. The time estimated to remove dirty catalyst and install fresh catalyst in its place was 24 shifts, which, assuming two shifts per day, would be 12 days. The time assumed for reactor cooldown was previously estimated as 48-60 hours, which would elapse during the first half of the boiler cleaning process[10]. After the fresh catalyst is in place, and the reactor access doors closed, the entire volume of fresh and dirty catalyst remaining in the reactor must then be heated to above the moisture dewpoint to avoid possible moisture condensation during boiler startup. This would involve use of the supplemental catalyst outage heating system, not the flue gas reheat system nor flue gas from the boiler. Burns & McDonnell estimated that post catalyst changeout outage time will extend approximately 36-48 hours until the boilers are ready to begin the startup process to return to service.

The November 2009 Supplemental NOx BACT Analysis study assumed 1168 total hours and 1126 total hours of outage time per year associated with MRYS Unit 1’s hypothetical application of low-dust and tail end SCR technologies (Scenario “B”), respectively. This is 980 hours and 938 hours of outage time in addition to the 188 hours of outage time per year assumed for advanced separated overfire air alternative. Assuming three catalyst layer changeout outages per year for Unit 1, this works out to be approximately 13 extra days per outage. Unit 2’s Scenario “B” assumed 1415 total hours of outage time for either hypothetical application of low-dust and tail end SCR technologies. This is 1234 hours of outage time in addition to the 181 hours of outage time per year assumed for advanced separated overfire air alternative. Assuming four catalyst changeout outages per year for Unit 2, this works out to be approximately 13 extra days per outage.

---

[10] See Reference 9, March 15, 2007, pages 12-14.

The November 2009 Supplemental NOx BACT Analysis study assumed 401 total hours and 443 total hours of outage time per year associated with MRYS Unit 1's, and 387 total hours and 428 total hours of outage time per year for Unit 2's, hypothetical application of tail end and low-dust SCR technologies (Scenario "A"), respectively. This is 213 or 256 hours of Unit 1 outage time and 206 or 247 hours of Unit 2 outage time in addition to the 181 hours of outage time per year assumed for advanced separated overfire air alternative. Assuming one catalyst changeout outage every two years for each Unit 1 and Unit 2, this works out to be approximately between 8.6 and 10.7 extra days per outage, depending on the boiler and SCR technology studied.

The catalyst changeout outage times assumed in the November 2009 Supplemental NOx BACT Analysis study for MRYS Unit 1 and the similar study for MRYS Unit 2 are expected to be extensions to the boiler cleaning outages. Note that the estimated annual number of days for catalyst changeout outages is in addition to outage times included in the Advanced Separated Overfire Air alternative, which is also relative to baseline operation which include downtime for boiler cleanings. We believe the outage durations and frequency are reasonable assumptions to use for the purposes of showing possible economic outcomes that could result from the hypothetical application of low-dust and tail end SCR technologies at MRYS.

NDDH Request #4: The indirect capital costs associated with the project appear to be high. A detailed explanation of the estimation method must be supplied.

BMcD Response:

Burns & McDonnell used standard estimating practices to estimate direct, installation, and indirect capital costs for MRYS Unit 1's and Unit 2's hypothetical application of low-dust and tail end SCR technologies. To establish the context of estimated indirect costs, we note that several major assumptions were used by Burns & McDonnell in developing the capital cost estimates of the hypothetical applications of low-dust and tail end SCRs at Milton R. Young Station. These assumptions include the following:

- A multiple (parallel prime) contracting approach was selected (as opposed to single "turnkey" or Engineer-Procure-Construct contract). Although this approach may increase the project execution risk to the Owner, the execution risk is considered manageable. This contracting approach was recommended because it allows early award of major equipment procurements to allow detailed design engineering to proceed expeditiously to meet the project schedule, and offers the greatest flexibility for the Owner (Minnkota) to be involved in key decisions regarding design.
- Project will be executed to achieve completion in 2016 for Unit 2 and 2017 for Unit 1. It was assumed that the project will be executed with skilled workforce resources sufficient to meet the target project execution schedule while minimizing overtime. No additional overtime is included to accommodate a compressed work schedule.

Indirect Costs:

- Escalation based on historical data and Burns & McDonnell experience was assumed to average 5% per year for equipment, 9% per year for materials and 5% per year for labor. See additional general description of escalation included below.
- Contingency was calculated at 20% overall (10% for pricing and 10% for scope). Contingency was applied to Total Direct Capital Costs plus Indirect Capital Costs such as Engineering and Field Support, Construction Management and related indirects, Startup Expenses, and Cost Escalation during Project Execution. Owner Contingency was estimated at 7%. See additional general description of contingency included below.
- A performance bond is included for all subcontract work at the rate of 1.5% of the estimated project contract costs.
- Sales tax on construction consumables is included. No other tax is included.
- Owner will provide a builder's risk policy for the project. Cost for this is included in the estimate of Owner's costs.
- Interest During Construction (IDC) is included in the Owner's costs at 6% per year, assuming project execution-based monthly expenditures.

Escalation:

An estimate for escalation of project costs has been included in the capital cost estimate. Escalation of construction labor, materials, and indirects was estimated based on historical data and Burns & McDonnell experience.

Escalation of construction labor was estimated to be approximately 5% annually throughout the project. This estimate of escalation was based on the average increase in craft labor costs for the United States combined with known union labor contract costs in the next few years. The average annual escalation of union contracts for skilled and common labor rates over the last ten years in North Dakota has been approximately 5.0% per year.

Escalation of equipment and materials is included in the project estimate at a rate of 5% per year for equipment and 9% per year for materials. Since January 2004, steel pricing experienced rapid escalation equating to a nearly a 100% increase in rebar and structural steel costs, then dropped in late 2008 and early 2009. Within the past 6 months, steel prices have again started to rise. Pipe and electrical commodities have also seen a high overall escalation during this time, followed by a decline in late 2008. Due to this volatility, equipment and material suppliers have been providing pricing with short bid validity.

Contingency:

This project involves a significant amount of retrofit work in the existing plant. The SCR Cost Estimate study did not perform a thorough review of existing conditions and interfaces with the new work. It is anticipated that the scope of work will increase as unknown conditions are discovered during project execution. A contingency of 20% of the overall project costs is included in the project cost. Of this 20%, 10% covers accuracy of the pricing of the equipment and materials (commodities), and 10% covers omissions from the defined project scope. This contingency is not intended to cover changes in the general project scope (i.e. addition of buildings, addition of redundant equipment, addition of systems, etc.) nor major shifts in market conditions that could result in significant increases in contractor margins, major shortages of qualified labor, significant increases in escalation, or major changes in the cost of money (interest rate on loans).

In addition to the project contingency, an additional owner contingency is included to cover owner general project scope additions. Based upon the amount of preliminary design and project definition completed, a 7% scope contingency to cover such potential changes is included. However, this contingency level depends on the probability of additional scope and is typically determined by the Owner (Minnkota).

NDDH Request #5: Support must be supplied for the cost of natural gas and electricity.

BMcD Response:

Burns & McDonnell used estimated long-term average natural gas unit cost for the economics of conventional and fuel-lean gas reburn alternatives' annual operating costs included in the 2006 NOx BACT Analysis Study reports for MRYS Unit 1 and Unit 2. The annual cost of auxiliary power consumed by air pollution control equipment and the value of electric generator output not able to be sold ("lost") due to inability to produce electricity during outages related to the air pollution control equipment associated with particular control alternatives were also calculated. The long-term average unit costs for natural gas and electricity were provided by Minnkota. Burns & McDonnell's recent review of the forecast power industry's natural gas unit cost forecasts from 2006 confirm that the number used in the original NOx BACT Analysis Study calculations and reports submitted in October 2006 are reasonable, given the uncertainty and variability that is common with such forecasts.

In the November 2009 Supplemental NOx BACT Analysis study reports, Burns & McDonnell assumed the economics of hypothetical application of low-dust and tail end SCR technologies at MRYS should be also based on the same unit costs used for the 2006 NOx BACT Analysis study reports.

NDDH Request #6: More details, including calculations, must be supplied to justify the pressure drops and parasitic loads associated with the SCR configurations.

BMcD Response:
Burns & McDonnell used estimated flue gas pressure drops provided by the SCR supplier for the SCR reactor, and gas-to-gas heat exchangers (GGH), in the development of new induced draft booster fans' performance requirements and the alternatives' economics of hypothetical application of low-dust and tail end SCR technologies at MRYS for Unit 1 and Unit 2 in the November 2009 Supplemental NOx BACT Analysis study reports. The estimated flue gas pressure drops of the flue gas ductwork, which would be incurred upstream and downstream of the low-dust and tail end SCR reactors and GGHs, were calculated using a proprietary spreadsheet.

For low dust SCR cases, new ductwork would be connected downstream of the existing induced draft fans' outlets and a new booster fan for each reactor would follow the GGH outlet after the SCR reactor, discharging to the existing flue gas desulfurization (FGD) system absorber inlet duct[11].

In tail end SCR cases, new duct connections downstream of the existing induced draft fans' outlets would divert flue gas before the FGD absorbers' inlet ducts, through the hot side of the FGD GGH then back to the FGD absorber inlet duct. Additional duct connections downstream of the existing FGD absorbers' outlet ducts would reroute flue gas through the cold side of the FGD GGH, then to the cold side of the main (SCR) GGH upstream of the flue gas reheat section in the SCR reactor. After the reactor, flue gas would pass through the hot side of the main (SCR) GGH, continue to the new induced draft booster fans, and be discharged back to new duct connections near the existing inlets to the chimneys[12].

Horsepower required to drive the fans to produce pressure needed to overcome the cumulative ductwork and SCR equipment pressure losses for full load (maximum continuous rating) and "test block" flue gas flows was calculated from budgetary booster fan equipment quotes, which included preliminary pressure rise versus flow and mechanical efficiency curves, from two fan vendors. The horsepower required for the volumetric gas flow and pressure rise was then converted into electrical kilovolt-amperes (kVA) and kilowatts (kW) in order to calculate auxiliary power loads. An annual average load factor was applied, which was then multiplied by the assumed hours of annual operation to determine the annual megawatt-hours (MW-h) of consumed auxiliary power due to the SCRs' induced draft booster fans.

---

[11] See attached sketch for low-dust SCR equipment and ductwork conceptual arrangement.
[12] See attached sketch for tail end SCR equipment and ductwork conceptual arrangement.

The parasitic loads associated with the SCR alternatives studied were determined by identifying known power-consuming auxiliary equipment serving the new air pollution control equipment. Estimates of design horsepower or kVA, based on vendor quotes or similar projects where information is available, were generated. Conversion to kW along with application of an annual average load factor resulted in estimated average annual auxiliary power loads, which were summed together to establish the total parasitic load. Annual megawatt-hours (MW-h) of consumed auxiliary power due to the various SCR cases studied were calculated by multiplying the total parasitic load by the assumed hours of annual operation.

The table below provides the results of these calculations.

Pressure Drop and Fan Power Calculation Results

Parameter	U1 LD	U1 TE	U2 LD	U2 TE
FGD GGH (hot side) pressure drop, in. w.g.	--	2.7	--	1.87
FGD GGH (cold side) pressure drop, in. w.g.	--	2.7	--	1.87
SCR GGH (cold side) pressure drop, in. w.g.	2.3	2.7	1.74	1.98
SCR reactor/catalyst press. drop, in. w.g.	2.0	2.0	2.0	2.0
SCR GGH (hot side) pressure drop, in. w.g.	2.3	2.7	1.74	1.98
SCR flue gas ducts/dampers/connections pressure drop, in. w.g.	5.4	6.2	4.5	6.3
Booster Fan Static Pressure Rise / Total Pressure[1] (Inches W.G.)	12.0 / 13.51	19.0 / 21.33	10.0 / 11.50	16.0 / 18.23
Booster Fan Motor Horsepower[2]	5000	7000	3500	5000
Load kVA / Demand kVA[3]	5000 /4500	7000 /6300	3500 /3150	5000 /4500
Quantity of Fans, capacity per fan, each case	One (1) x 100%		Two (2) x 50%	

1- Booster fan static pressure rise is the sum of the duct and SCR equipment pressure drops. Total fan pressure includes fan static pressure rise plus additional pressure rise required to overcome pressure drops within the fan equipment. These numbers do not include additional fan capacity (margin) above the amount required for full load (maximum continuous rating or MCR) operation, which allows for factors that reduce actual performance over sustained periods of running. Static pressure rise and Total pressure numbers are preliminary; final design may require values higher or lower than those shown.

2- Motor horsepower is greater than fan mechanical horsepower, and is based on available size larger than "Test Block" horsepower. Mechanical horsepower takes into account fan mechanical efficiency at the stated operating condition. Fans are sized based on mechanical efficiency and additional capacity (margin) above the MCR condition, referred to as "Test Block". The test block flow margin is 15% per fan, the test block pressure rise margin is 32.25% (1.15^2) above MCR values stated above. Test block fan mechanical efficiency is approximately 0.8. Fan Mechanical Horsepower = flue gas volumetric flow (actual cubic feet per minute) multiplied by pressure rise in inches w.g. divided by (6536 x efficiency). Fan efficiency varies with flow and pressure rise; values based on estimates/vendor quotes for full load (maximum continuous rating or MCR) conditions.

3- Horsepower (motor rating) is approximately equal to Connected Load kVA; Connected Load kVA x Estimated Annual Average Demand factor = Demand Load kVA.

Hypothetical applications of low-dust and tail end SCR technologies included estimates of auxiliary electrical power usage. It is important to note that some alternatives identified between 88 and 109 electricity-consuming items supplying or serving each SCR reactor system. Several pieces of auxiliary equipment with significant electrical power loads were included. These are: sootblowing air compressors with dryers; instrument/service air compressors with dryers; seal air fans for SCR reactor inlet and outlet flue gas isolation dampers; SCR flue gas reheat burner combustion air fans; drive gearboxes for rotary gas/gas heat exchangers; urea-to-ammonia dilution air/combustion air fans; auxiliary equipment service building ventilation/heating/lighting; and urea feed pumps. The instrument/service air and sootblowing air compressors are significant but necessary to supply dry compressed air used by equipment dedicated to control, maintain, and provide catalyst cleaning media for the SCR systems.

NDDH Request #7: All vendor correspondence related to SCR reactor sizing, catalyst volume, NOx control efficiency, catalyst cost, catalyst replacement schedule, and catalyst guarantees should be provided. This includes the original requests submitted to vendors and analyst [catalyst] suppliers by Minnkota and its consultants. This must also include the description of the gas stream that was supplied to the vendors.

BMcD Response:
Information responsive to this request by Minnkota, Burns & McDonnell and the SCR system supplier and SCR process design consultant, catalyst vendors, and flue gas particulate characterization consultant is being submitted (see Enclosures). Documents that include information considered as “trade secrets” per the NDDH’s Air Pollution Control rules are being submitted and marked “confidential” (see Enclosures).

Minnkota developed agreements with the catalyst suppliers and flue gas particulate characterization consultant engaged in this effort, and has a general services agreement with Burns & McDonnell, which covers work done by the SCR system supplier and SCR process design consultant. Information provided under Enclosure C is considered non-confidential, and includes information for which no claim is being made for confidentiality, along with an index and summary of the information submitted which is suitable for release to the public. Enclosure D includes documents claimed to contain trade secrets which are requested to be treated as confidential, along with an affidavit stating how and why the information fulfills the conditions of confidentiality per the NDDH’s Air Pollution Control rules describing this confidentiality procedure.

NDDH Request #8: Data must be provided for the temperature gradient of the regenerative heat exchanger to justify the reheat calculations. This must be provided for the both LDSCR and TESCR. The 600ºF temperature for the reheated flue gas must be justified.

BMcD Response:

The preliminary design temperatures for the hypothetical applications of low-dust and tail end SCR technologies shown in the table below were calculated by the SCR process consultant. The temperature data tabulated below for the Unit 1 low dust (LD) case include corrections identified by the SCR process consultant as described further in the response to NDDH Request #11.b. The SCR system supplier, which provided pricing of SCR equipment, including GGHs for low-dust and tail end SCRs, did not provide estimates of the GGHs' process performance.

SCR Process Design Temperatures

Parameter	U1 LD	U1 TE	U2 LD	U2 TE
FGD GGH (hot side) inlet temperature, ºF	--	335	--	331
FGD GGH (hot side) outlet / FGD Absorber Inlet temperature, ºF	--	(1)	--	(1)
FGD GGH (cold side) inlet/ FGD Absorber Outlet temperature, ºF	--	142	--	143
FGD GGH (cold side) outlet temperature, ºF	--	150	--	151
SCR GGH (cold side) inlet temperature, ºF	335	150	331	151
SCR GGH (cold side) outlet temperature, ºF	535	520	535	520
Flue Gas Reheat Burner outlet / SCR Ammonia Injection Grid/Reactor inlet temperature, ºF	580	563	580	563
SCR GGH (hot side) outlet temperature, ºF	380	199	380	197
FGD Absorber Outlet temperature, ºF	142	142	143	143

1- The temperature of the FGD GGH hot side outlet (discharges to FGD Absorber Inlet) was not provided by the SCR process consultant. It would be less than 330ºF.

As can be seen in the table above, the flue gas is reheated by natural gas to either 580ºF for low-dust SCR cases or 563ºF for tail end SCR cases. Natural gas heat input rates used in the November 2009 Supplemental NOx BACT Analysis study reports assumed these flue gas temperatures. These preliminary process design temperatures have not been confirmed pending final design by the gas/gas heat exchanger manufacturer. The catalyst vendors recommended that the catalyst be designed for (able to withstand continuous exposure to) 600ºF service operating temperature. The capacity of the reheat burner equipment was not specifically provided by the SCR system supplier, but was expected to be capable of raising the flue gas up to the recommended service temperature.

NDDH Request #9: A comparison of the SCR costs at M.R.Young Station versus PSE&G Mercer Station and We Energies Oak Creek Station should be provided or an explanation why such a comparison is not possible or inappropriate. We recognize that each plant has unique characteristics and there will be some design differences from plant-to-plant, but those differences should not necessarily dismiss making general comparison of costs unless there are unique or extenuating circumstances which would preclude a general cost comparison.

BMcD Response:

A BACT analysis is performed on a case-by-case, site-specific basis. It is inappropriate to compare the capital costs associated with the low-dust SCR installation at Mercer Station, or at South Oak Creek Station, against those developed for the hypothetical applications of low-dust and tail end SCR technologies at MRYS. Site conditions, boiler firing type, type and characteristics of fuels burned and resulting flue gas emissions and ash produced, and the limited amount of NOx reduction required for those referenced low-dust SCR cases that were not required to represent BACT, make the comparison not relevant to MRYS.

NDDH Request #10: Provide additional clarification and technical justification regarding Minnkota's determination that the units at MRYS are boiler limited and cannot generate additional steam for flue gas reheating purposes.

BMcD Response:

The steam turbine-generators at MRYS have a given output (gross megawatts) based on steam pressures, temperatures and flow rates related to the boilers. Removing high pressure/high temperature steam to use for flue gas reheating will directly cause a reduction in electrical output. This output reduction cannot be compensated for by increased boiler steam generation without unreasonable consequences. The boilers generate steam based upon their fuel heat input (firing) rates and capacities to absorb the heat created from the fuel combustion. The efficiency of converting fuel heat to steam to megawatts (heat rate or Btu per gross kilowatt) is limited by many factors. Fuel characteristics and boiler capacity are factors that impact heat rate (efficiency) that are not easily changed in the positive direction. The current fuel quality coming from the adjacent mine is not within the original design parameters of the boilers.

Because of the firing type (cyclone) and characteristics of North Dakota lignite burned and resulting flue gas emissions and ash produced at MRYS, the amount of fouling of the heat-absorbing surfaces within the boiler system is severe. These fouling conditions cause high exit flue gas temperatures that eventually reach the maximum limit recommended for maintaining the integrity of the air preheaters. This is indicated by the time-temperature graphs previously provided[13] and repeated below. The rate of boiler surface fouling increases significantly as more coal is fired, especially at maximum sustainable firing rates.

Due to the sticky character of the ash deposits, an “arsenal” of sootblower and water lance equipment is employed by Minnkota in an attempt to reduce the rate of fouling accumulations during boiler operations and remove these deposits during frequent boiler outages. These boiler cleaning outages occur every three to four months depending on the specific unit and the fuel quality delivered during the period. If the firing rate is increased to generate more steam for other heating purposes, the frequency of the cleaning outages must be increased. If the accumulated deposits are not removed, the frequency of the cleaning outages must be increased or the firing rates must be reduced and thus reduce the steam and electrical output of the boilers and steam turbine-generators. There is not “excess steam available for flue gas reheating” that would allow Minnkota to avoid reduced annual power generation.

NDDH Request #11: There appear to be several discrepancies in the documents that must be addressed including:

a. **The catalyst volume for Unit 2 (p. 4-23) is listed as 256 m^3 per reactor or 512 m^3 per layer. This is 4-5 times more than Unit 1 yet Unit 2 is not twice as large. Please verify the Unit 2 catalyst volume.**

At page 4-23, the words “per reactor” should be deleted from the sentence describing Unit 2’s catalyst volume. This will be shown on an “Errata Sheet” attached to this document.

For Unit 2, the total initial volume was 768 cubic meters for three layers, or 256 cubic meters per layer, based on catalyst vendor input. Subsequent installation of 342 cubic meters for the fourth layer was assumed, also based on catalyst vendor input. Total initial volume plus first fill of spare layer equaling 1110 cubic meters is for two SCR reactors for each case studied for Unit 2. The correct catalyst volumes were used in the annual operating and maintenance cost calculations that are a portion of the levelized total annual costs for NOx control alternatives provided in the referenced November 2009 Supplemental NOx BACT Analysis study reports.

The conceptual design of Unit 1 Low-Dust SCR Reactor, and Tail End SCR Reactor as provided by the catalyst supplier included in each layer a total of 104 catalyst modules (8 x 13 arrangement). There is one SCR reactor for each case studied for Unit 1. The conceptual design of Unit 2 Low-Dust SCR Reactor, and Tail End SCR Reactor included in each layer a total of 91 catalyst modules per reactor (7 x 13 arrangement). There are two SCR reactors for each case studied for Unit 2.

b. **The reheat for Unit 2 for TESCR is listed as 48.11 MMBtu/hr per reactor and for LDSCR is 45.55 MMBtu/hr per reactor. The differential between TESCR and LDSCR is much less than for Unit 1 (60.3 MMBtu/hr and 31 MMBtu/hr).**
Please explain this difference.

The preliminary process design calculations were reviewed for the hypothetical applications of low-dust and tail end SCR technologies for Unit 1 and Unit 2. It was determined from this review that the temperature rise for the Unit 1 LDSCR flue gas reheat system was incorrectly assumed to be 25 degrees F instead of 25 degrees C (equivalent to 45 degrees F). The corrected 45 degrees F temperature rise for the Unit 1 LDSCR flue gas reheat system is shown in the table included with the response to NDDH Request #8. The correct natural gas heat input rate for Unit 1’s low-dust SCR cases is 54.5 MMBtu/hr (instead of 31 MMBtu/hr).

The discovery of the underestimate of Unit 1’s low-dust SCR flue gas reheat fuel requires revision to the MRYS Unit 1 November 2009 Supplemental NOx BACT Analysis study report for “Scenario A” and “Scenario B” cases. A revised version of the referenced November 2009 MRYS Unit 1 Supplemental NOx BACT Analysis Study report document and the December 2009 response document is being submitted with the corrected numbers and recalculated control costs (see Enclosures). The flue gas reheat fuel rates and costs assumed for the hypothetical applications of Unit 1’s tail end and Unit 2’s low-dust and tail end SCR alternatives included in the November 2009 Supplemental NOx BACT Analysis study reports will not change.

The temperature rise for the Unit 1 TESCR, Unit 2 LDSCR, and Unit 2 TESCR flue gas reheat systems are also shown in the table included with the response to NDDH Request #8. These are all preliminary numbers that would require confirmation after final cold-side outlet design temperatures are established by the FGD and SCR gas/gas heat exchanger manufacturer.

c. The capital costs for the “stand alone” SCR (p.3 of attachments to December 11, 2009 submittal) do not total correctly. Please check the numbers and revise the documents as necessary.

The numbers for “Pricing Contingency” shown in the table that provided “Estimates of Total Capital Investment for Low Dust and Tail End Selective Catalytic Reduction Alternatives Best Available Control Technology – Supplemental Analysis Stand Alone” cases submitted on December 11, 2009 were incorrect. They should match the “Scope Contingency” numbers above the “Pricing Contingency” line in the table. A revised version of the referenced document is being submitted containing the table with corrected data (see Enclosures).

d. The flue gas reheat burners and fans appear to be included in both “SCR system equipment” and “Auxiliaries” cost estimates (see p.4 of attachments to December 11, 2009 submittal, footnotes 1 and 3). Please check this and revise the documents as necessary.

There are two systems of natural gas-fired burners associated with each alternative studied for hypothetical application of low-dust and tail end SCR technologies in the November 2009 Supplemental NOx BACT Analysis study reports. The “flue gas reheat burner equipment” is correctly included as part of the “Purchased Capital Equipment SCR System Equipment” item (1) (a) under “Direct Capital Costs” denoted by footnote number1 in both tables of “Estimates of Total Capital Investment” for “Shared Facilities” and “Stand Alone” as submitted on December 11, 2009. Item (1) (b) “Auxiliaries/Balance of Plant” of both tables has footnote number 3. This footnote should be revised to read as follows: "Includes service air and sootblower air compressors, induced draft booster fan(s) and dampers, urea-to-ammonia conversion ~~flue gas reheat~~ equipment with natural gas-firing burners and fan(s), SCR bypass ducts and isolation dampers, interconnecting ductwork, equipment for active coal yard storage modifications, and catalyst standby heating auxiliary equipment costs as well as mechanical setting of this equipment". A revised version of the referenced document with the corrected footnotes is being submitted (see Enclosures).

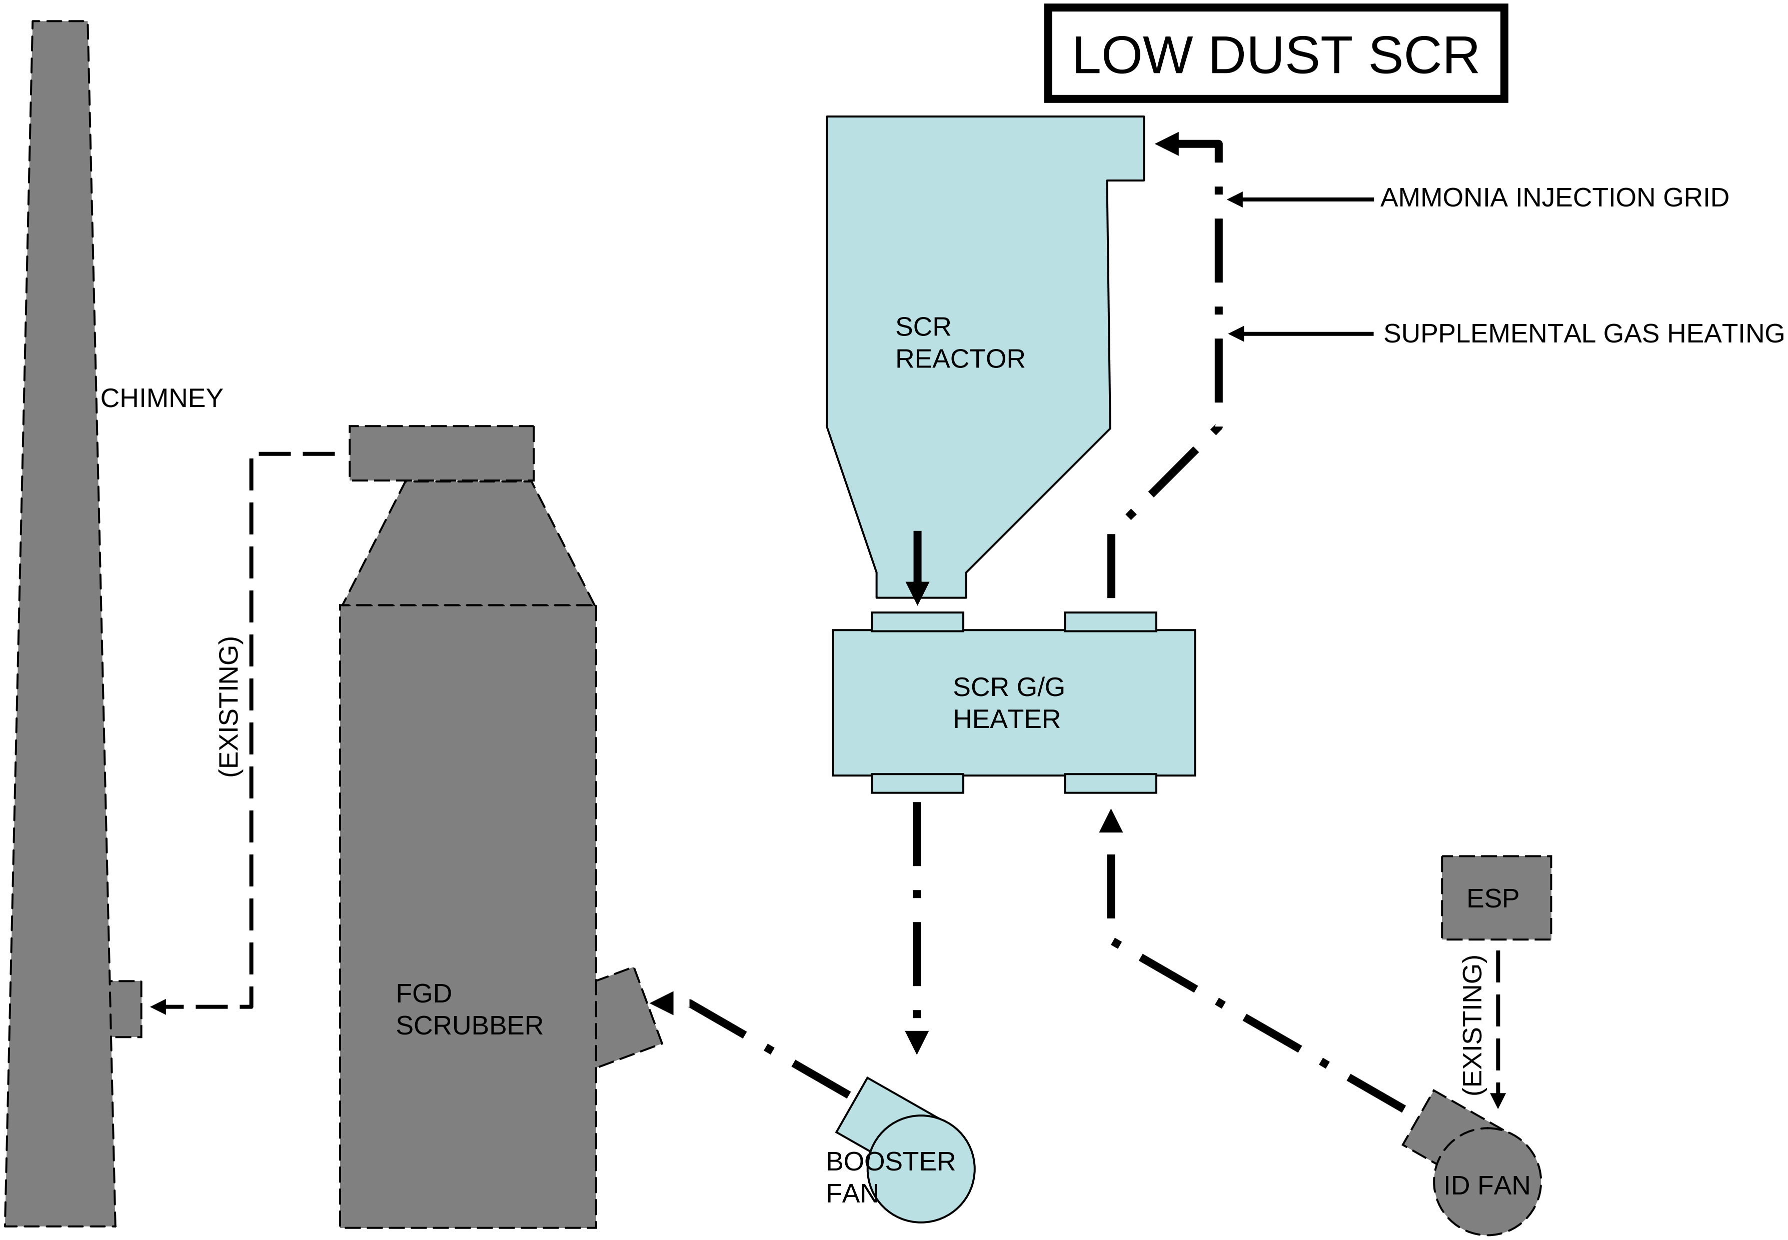
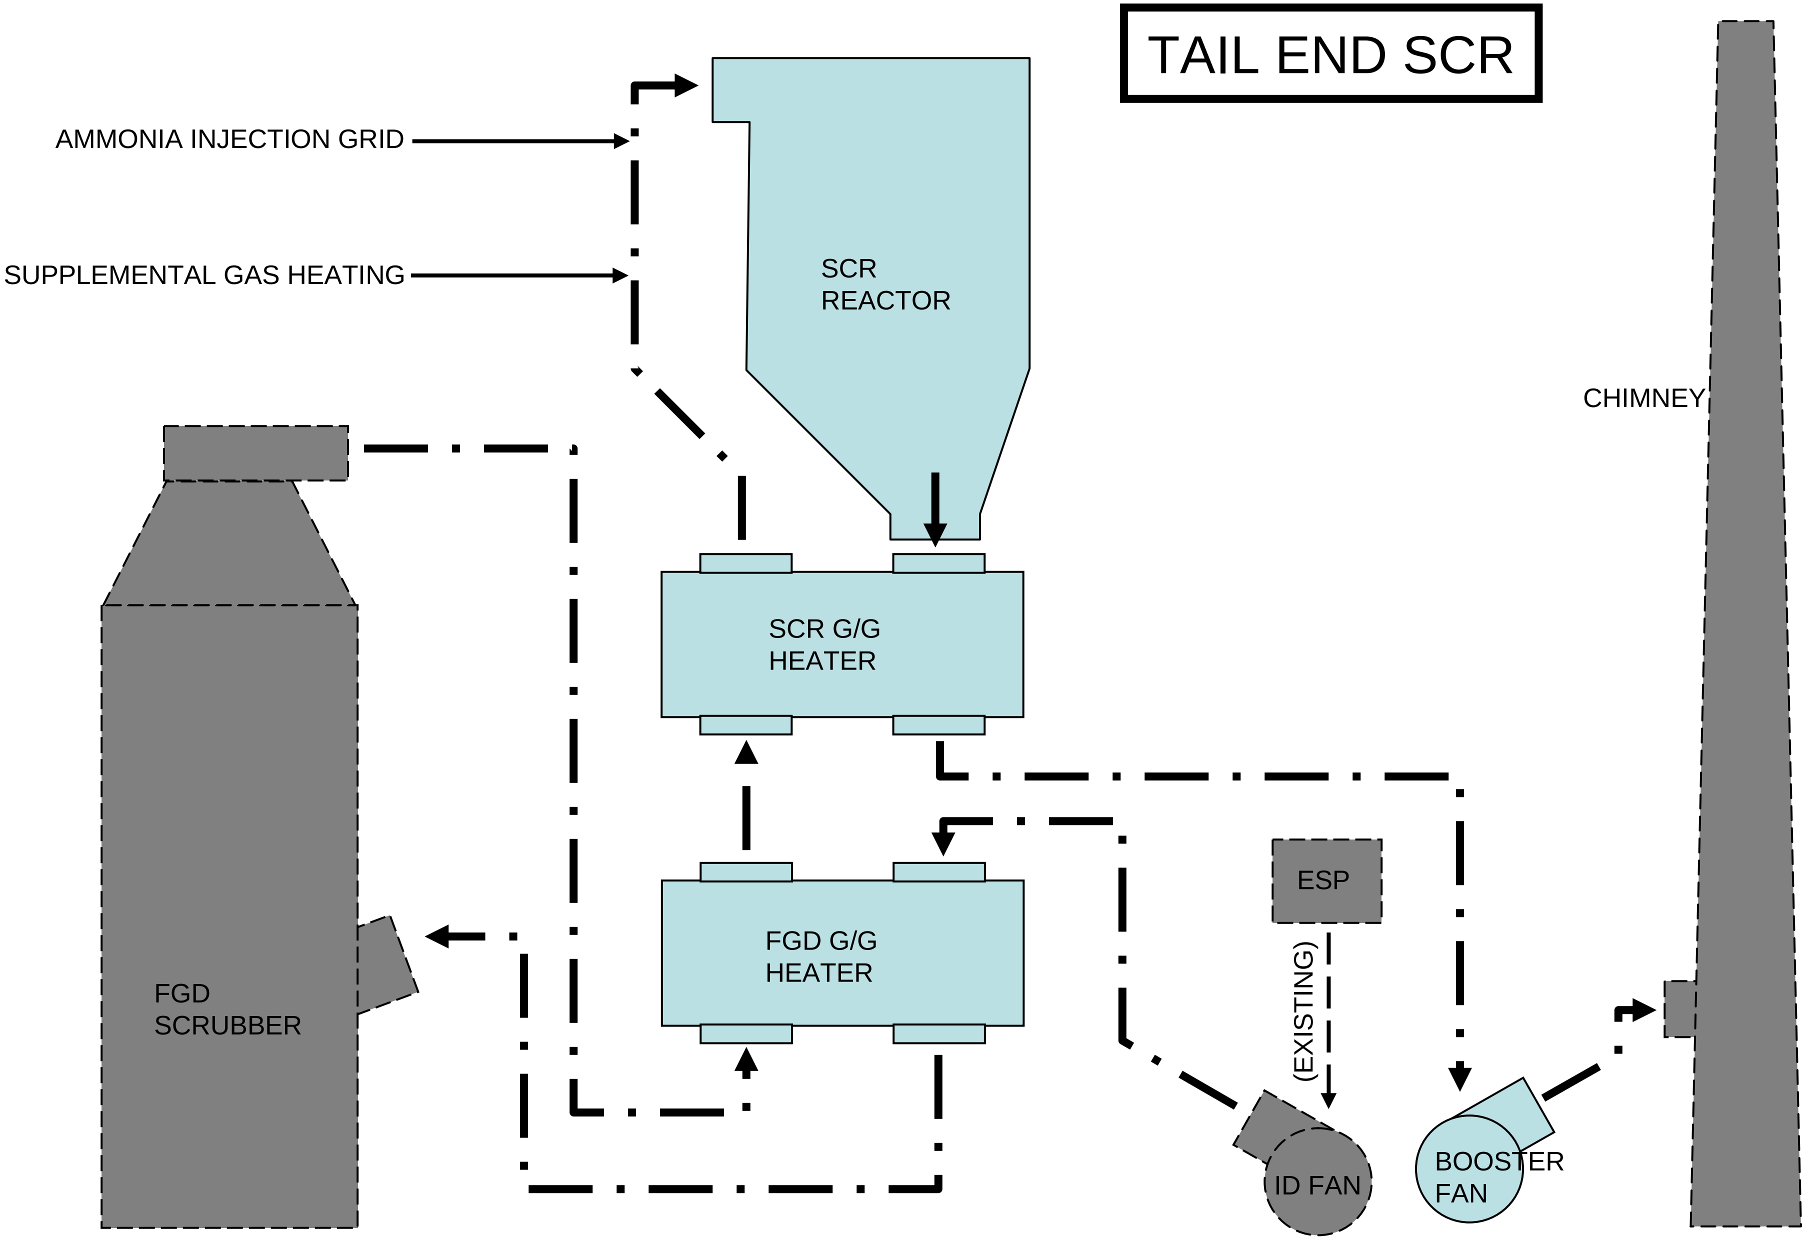
LOW DUST SCR



SKETCH SK – FD2

TAIL END SCR



ERRATA – MRYS Unit 2 Supplemental NOx BACT Analysis Study Report (November 2009)

Unit 2 Supplemental NOx BACT Analysis Study Report November 2009, page 4-23:

The second sentence of the paragraph should be revised to delete the words “per reactor”:

> SCR catalyst replacements are additive to the general annual hypothetically-applied low-dust and tail end SCR equipment maintenance. Catalyst replacement costs are based on catalyst vendor quotation of volume of catalyst, estimated to be three layers initially (top, middle-upper and middle-lower) at 256 cubic meters per layer ~~per reactor~~ for two reactors in parallel. A fourth (bottom) layer at 342 cubic meters is expected to be required after initial operation of hypothetically-applied full-time tail end or low-dust SCR alternatives, as part of the catalyst replacement program. Catalyst replacement costs for the hypothetical application of SCR alternatives were estimated for the two different catalyst management scenarios described above.

Subject: RE: Hypothetical TE-SCR Cost Estimate

Volker & Bob –

We have been asked by one of our northern Midwest clients to perform a BACT cost-effectiveness analysis assuming that a custom tail-end SCR system could be retrofit on each of two coal-fired boilers.

We need help in developing capital cost and O&M cost estimates for retrofitting TESCR to existing units that use dry ESPs with lime-based wet FGD systems upstream. The normal operating and maintenance costs will be based on less than maximum design boiler heat input and flue gas flow conditions upon which the TESCRs would be designed for.

We will need advice as to what assumptions would be included in the process design for flue gas reheat, amount of catalyst, unit catalyst cost, frequency of catalyst replacement or washing, length of time periodic catalyst changeout, flue gas pressure drop from scrubber outlet to chimney inlet, and NOx reduction and ammonia consumption performance targets.

We will need the above estimates in a very short time period – before the end of January, with preliminary numbers by mid-January.

We would also like to get some idea as to the amount of calendar months required for implementation: scoping, vendor identification, investigation, design, procurement, construction, startup and commissioning, and outage time required for the initial installation tie-ins.

We can provide data for fuel, boiler heat input, NOx emissions and excess air/flue gas volume from the boiler outlet, sulfur dioxide removal by the wet FGD scrubber, and particulate loading.

If you have a spreadsheet, I can fill-in, or we can give you what we have as mentioned above.

We will work out the contractual agreement as we proceed, if that is okay.

Let me know how we can get this going.

Bob,
Volker and I can support you on this. We can quickly run a mass balance once we get the process data.
I will be at Burns & McDonnell tomorrow; perhaps we can get together briefly to discuss.
Thanks, Bob

Subject: RE: Hypothetical TE-SCR Cost Estimate

Bob,
In order to run the mass balance for the TE SCR, we need the following process data:
Flue gas volumetric flow rate
Flue gas mass flow rate
Flue gas composition downstream of the FGD system
Flue gas temperature
NOx reduction requirements
Maximum SO2 oxidation rate

Once we get started, we'll let you know if we need anything else.

From this, we can estimate reheat requirements, catalyst volume, pressure drop, NH3 consumption.

Best Regards, Bob

Subject: RE: Hypothetical TE-SCR Cost Estimates

Volker & Bob –

One process parameter I did not mention that should be considered in the TESCR system design basis is the outlet gas temperature going to the stack, after the GGH on the back-end of the TESCR.

The new chimney that is being constructed for Unit 2 will have a fiberglass-reinforced plastic liner for the flue gas, and we have advised the chimney vendor that the design temperature range is 130 to 200 degrees F (continuous), with a maximum excursion to 350 degrees F for 15 consecutive minutes (transient condition due to FGD system malfunction).

The existing chimney being retrofit for Unit 1 currently has a metal liner that may receive added corrosion protection using alloy metal "wallpaper" lining or borosilicate glass block that is capable of sustained operation up to 200 degrees F, with higher excursions for short durations, similar to Unit 2's case.

Please advise a time-frame when you think that you will have a preliminary design basis and cost numbers.

Bob & Volker –

We need review of our assumed TESCR catalyst replacement plan, saved as an Excel spreadsheet <MRYS TESCR Catalyst Mgt (BMcD draft 1-15-09).xls> at the new ft site:

[redacted]

As part of the BACT cost effectiveness analysis, we also need to know what to assume for catalyst volume per layer, and unit cost (labor & materials) assumed to be required per replacement layer.

Thanks,

Bob Blakley

Subject: RE: Mass Balance for Hypothetical SCR Installation

Bob & Volker –

Several items to discuss and consider:

1. The U2 FGD absorber vessels (two in parallel configuration) are not designed for 14.5 in. w.g. internal pressure; I believe they have a much lower limit; operationally it is around 4 in. w.g., but I do not know the exact design value. We are looking into hiring a company that can perform a finite element analysis of the absorber vessels, but that will not be started for several months from now. I assume this means that a booster fan will be needed after the FGD GGH, upstream of the SCR GGH, to overcome the pressure drops across the GGHs.
2. We have assumed (and Minnkota is directing us to do so) that the source of heat for the final reheating of the flue gas downstream of the SCR GGH and upstream of the reactors should be fired natural gas or propane, not steam. So the effluent of the direct-fired burner(s) and the associated NOx emissions also must be accounted for in the reactor design and NOx removal. Conservatively, burners should be assumed to be supplied with ambient air for combustion and emit 0.1 lb/mmBtu (per million BTU), unless this is not feasible or there are other reasons to change this assumption.
3. I don’t know if this makes a difference, but Minnkota is expecting to store liquid urea concentrate (40-50% solution) on-site as the NOx removal reagent, and so some sort of conversion process will be needed to supply ammonia to the reactors. The plant site does not have direct rail access, so all consumable materials have to be transported by tanker trailer to be offloaded near the U2 boiler building.

We will need a similar preliminary mass balance for a low-dust SCR configuration for Unit 2, as well as both low-dust and tail-end SCRs for Unit 1.

We can arrange a phone conference for Monday to discuss. Carl will be back late tonight. We also need the numbers on catalyst volume and changeout frequency and costs.
Dave Blackwood is leading the scope definition and cost estimating effort from our Development Engineering department here in our Energy group.

We appreciate the information and will continue to work on this in a parallel-path effort. We can discuss this on Monday. Please let us know your availability for a phone conference or visit.

Subject: Mass Balance for Hypothetical SCR Installation

Bob,
Attached are a Mass Balance and PFD for a Hypothetical Tail End SCR for your review.
Please note:
1. 2 SCR reactors will be required for the installation;
2. The PFD denotes flue gas mass flow in kg/hr and temperature in degrees C. You can identify the specific process stream (noted in blue) and see this information converted into lb/hr and degrees F on the Mass Balance sheet.

We are still evaluating this and will provide more information later today.
Thanks, Bob

Subject: Hypothetical Case_Tail End SCR

Bob,
Attached are the latest Mass Balances and PFDs for the Steam and Nat Gas reheat cases. We revised the Steam case from the version previously sent.

We will be working on the Low Dust case as soon as we thoroughly review the revised spreadsheet you sent. We were both out of town last week.

Let us know if you have any questions.
Thanks, Bob

Bob & Volker –

We will review your recent mass balances for Unit 2.

Do you expect there to be a FGD GGH and booster fan downstream of the existing U2 wet lime FGD absorbers, upstream of the TESCR GGH? We expect the existing ID fans, or their replacements, will control boiler draft, so the TESCR will need a booster fan to overcome the GGH, reactor, and GGH treated side pressure drops.

As mentioned previously, I believe the typical FGD outlet pressure on U2's existing scrubbers is around 3-3.5 in. w.c., with 330-340 degF inlet gas entering the towers, at full load conditions (approx. 4800 mmBtu/hr boiler heat input). The absorber vessels are not rated to operate beyond around 4 in. w.c., which we are attempting to confirm.

The 5,158 mmBtu/hr heat input rate in the design basis is for short term, maximum output operation, for the plant's reserve capacity rating.

I also need to know the equation for converting ACFM or SCFM to normal cubic meters (Nm3). We're trying to calculate particulate and sodium loading expected to enter the LDSCR and TESCR reactors, in terms of milligrams or micrograms per Nm3.

Bob,
Attached are the latest Mass Balances and PFDs for the Steam and Nat Gas reheat cases. We revised the Steam case from the version previously sent.

We will be working on the Low Dust case as soon as we thoroughly review the revised spreadsheet you sent. We were both out of town last week.

Let us know if you have any questions.
Thanks, Bob

Bob & Volker -

One of the decisions from the SCR cost estimate study kickoff meeting with Minnkota last Thursday, February 26 was to assume natural gas firing for supplemental flue gas heating for both LD and TESCR cases for MRYS Unit 1 and Unit 2. Minnkota has established this as their reheat source they prefer.

In addition, Minnkota directed BMcD to assume urea for the ammonia source. Our understanding is that this may slightly affect the SCR mass balances when the urea is converted to ammonia before being injected into the flue gas stream because of the CO2 and water that will be driven off. The urea solution will be stored at 50% concentration on-site prior to feeding.

Please consider these decisions so that you can revise the preliminary mass balances for the LD and TESCR cases for MRYS Unit 1 and Unit 2 and provide estimated reactor sizing.

We would like to get the revised mass balances within 1 week and the preliminary reactor sizing by mid-March if possible. I don't know what the latter entails, so advise an alternate time table if this is more complicated than I realize.

Please advise if question arise.

Thanks,

I don't envision Minnkota having ammonia storage tanks in addition to the concentrated urea storage tanks, if the urea-to-ammonia conversion isn't "on demand".
I assume either a FT "Ultra" system or the hydrolyzer approach would satisfy that requirement.

My guess is since Minnkota has chosen natural gas-fired final reheat for the flue gas ahead of the SCR reactor for either LD or TE SCR cases as the energy source, rather than steam, they would probably go with the Fuel Tech version that uses fuel to decompose the urea rather than a hydrolyzer that uses steam.

I suppose it may depend on how much heat is required and what steam conditions are involved for the hydrolyzer. I am not familiar with that process but I'm sure we could check into that from another SCR project is needed.

Bob,
Thanks. We will revise the mass balances, but it will probably take until next Friday.
Has Minnkota determined the type of urea system? one requires steam for the hydrolysis and Fuel Tech's requires a combustion fuel. in this case, we would use the natural gas. Our system will affect the mass balance due to additional NOx, and byproducts such as H_2O and CO_2. We wouldn't account for trace byproducts.

The reactor size is easier, but mid-March is fine as a deadline.

Just to confirm, you need 4 mass balances: LD and TE for both MRYS 1 and 2.

Best Regards,
Bob

Bob –

I checked on the Seminole SCR project – it appears to use 125 psig saturated steam for the heat source in the urea-to-ammonia conversion process, and electric resistance heat tracing on the urea and ammonia lines.

Oh, and I am confirming that we need information on four cases:
U1 LD and TESCR; and
U2 LD and TESCR.

Has Minnkota determined the type of urea system? one requires steam for the hydrolysis and Fuel Tech's requires a combustion fuel. in this case, we would use the natural gas. Our system will affect the mass balance due to additional NOx, and byproducts such as H2O and CO2. We wouldn't account for trace byproducts.

The reactor size is easier, but mid-March is fine as a deadline.

Just to confirm, you need 4 mass balances: LD and TE for both MRYS 1 and 2.

Best Regards,
Bob

Subject: RE: Hypothetical Case_Tail End SCR

Bob & Volker -

One of the decisions from the SCR cost estimate study kickoff meeting with Minnkota last Thursday, February 26 was to assume natural gas firing for supplemental flue gas heating for both LD and TESCR cases for MRYS Unit 1 and Unit 2. Minnkota has established this as their reheat source they prefer.

In addition, Minnkota directed BMcD to assume urea for the ammonia source. Our understanding is that this may slightly affect the SCR mass balances when the urea is converted to ammonia before being injected into the flue gas stream because of the CO2 and water that will be driven off. The urea solution will be stored at 50% concentration on-site prior to feeding.

Please consider these decisions so that you can revise the preliminary mass balances for the LD and TESCR cases for MRYS Unit 1 and Unit 2 and provide estimated reactor sizing.

We would like to get the revised mass balances within 1 week and the preliminary reactor sizing by mid-March if possible. I don’t know what the latter entails, so advise an alternate time table if this is more complicated than I realize.

Please advise if question arise.

Thanks,

Subject: Hypothetical Case_Tail End SCR

Bob,
Attached are the latest Mass Balances and PFDs for the Steam and Nat Gas reheat cases. We revised the Steam case from the version previously sent.

We will be working on the Low Dust case as soon as we thoroughly review the revised spreadsheet you sent. We were both out of town last week.

Let us know if you have any questions.
Thanks, Bob

Subject: 12Mar09_Preliminary Information

Bob,
Attached are preliminary mass balances and PFDs for the LD and TE hypothetical cases. We have updated these to reflect natural gas firing to control temperatures to the SCR inlet. We have also based these on the use of Fuel Tech's ULTRA system for decomposing urea to ammonia. You will see the various inputs on the PFDs.

Also, we have prepared a table with preliminary reactor sizes. For all 4 cases, we have assumed 2 reactors per unit.
But, for Unit 1, 1 large reactor would also be possible for both cases. This is possible since the mass flow rate of the flue gas is less than 2,000,000 kg/hr.

Please let us know if we can clarify anything.

Best Regards, Bob

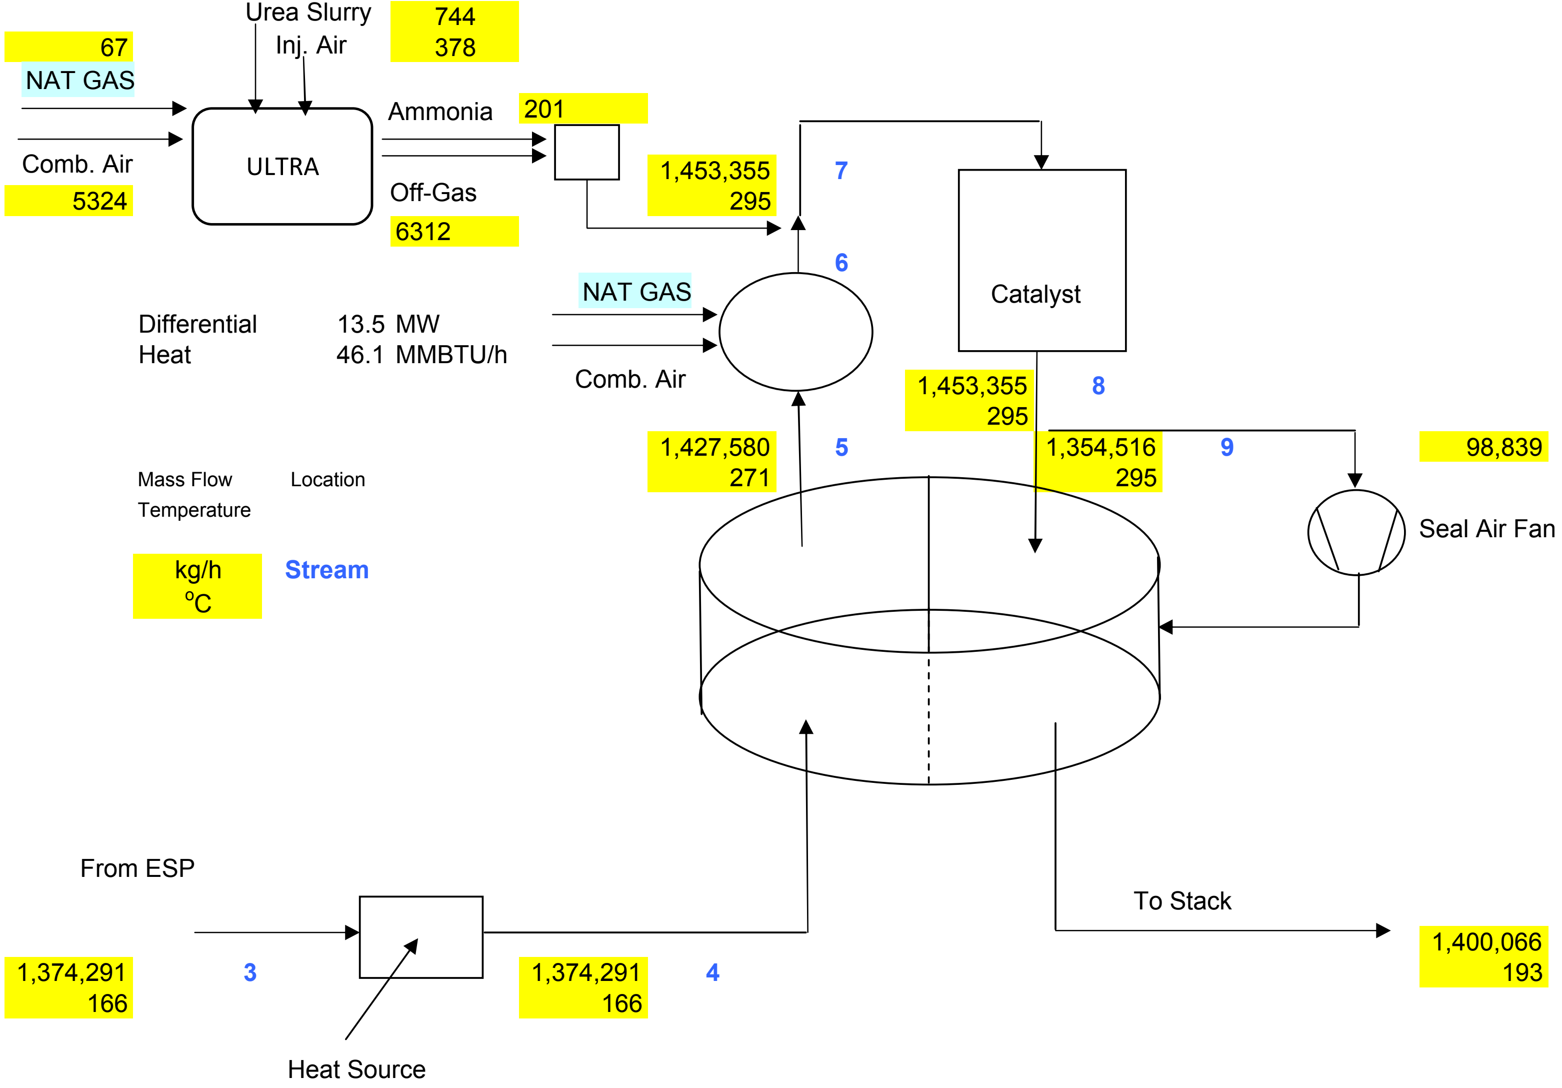
MRY 2 Low Dust SCR Process Flow Diagram Natural Gas Fired Reheat



Bowman, Chris

From: Bowman, Chris
Sent: Friday, March 20, 2009 2:55 PM
To: MGialanella@babcockpower.com
Cc: 'bbasile@babcockpower.com'
Subject: FW: Low Dust/Tail End SCR
Attachments: Lignite fuel analysis (1-09).pdf; MRY - Flue Gas Conditions.pdf

The listed SCR COD dates for each unit were incorrect. COD schedule of the low dust or tail end SCR at MRY would be negotiated with vendors to determine the soonest COD date possible.

Have a great weekend,

Christopher Bowman

Subject: RFQ: Low Dust/Tail End SCR

Mario,

As discussed on the phone, Minnkota Power is looking to add an SCR to each existing unit at their Milton R. Young Power Station (MRY). Due to the high sodium content of the coal, we are requesting budgetary equipment quotes of a Low Dust and Tail End SCR arrangement for each unit at MRY. The Low Dust SCR will be located downstream of each units ESP and the Tail End SCR will be located downstream of each units WFGD. The estimated flue gas for each associated option and coal analysis is attached.

General Information:
Unit 1, 257 MWg, cyclone-fired, subcritical, SCR COD December 2010
Unit 2, 477 MWg, cyclone-fired, subcritical, SCR COD December 2011
Fuel: Each unit burns 100% North Dakota Lignite.
Ammonia Reagent: 50% Urea solution
Location: Center, North Dakota – Milton R. Young Station

Each system should be based upon the following components and specifications:

- SCR system w/ gas bypass for maintenance (approx. 12.5% of total gas volume)
- Reactor housing
- Catalyst
- Associated flues and internal flow distribution devices
- Ammonia injection grid
- Hoists and monorails for SCR internal maintenance
- Sonic horns
- Natural gas reheater
- Regenerative gas to gas heat exchanger

- Associated interconnecting piping
- Freight to Center, North Dakota

Provided by others:

- Ductwork to and from SCR
- Structural support steel
- Foundations
- Electrical equipment and controls
- Air compressors
- ID Fans and/or booster fans
- Urea to Ammonia supply system

Please base each systems design assuming guarantees to be provided for NOx reduction as follows:
SCR Inlet NOx: 0.50 lb/MMBtu
Stack Outlet NOx: 0.075 lb/MMBtu
Heat Input (Max / Min):

- Unit 1: 2,995 / 2,744 MMBtu/hr
- Unit 2: 5,158 / 4,885 MMBtu/hr

Information required as soon as possible (estimated):

- Equipment dimensions and layout requirements
- Heat exchanger weights
- Pressure loss for each piece of equipment
- Ammonia consumption, slip rates, and natural gas consumption

We are requesting budgetary pricing of each system by **June 1st** in present day dollars with breakout of the catalyst pricing. Please let us know if you will be able to meet this deadline.

Thank you for your continued assistance and please call if you have any questions.

Subject: RE: Low Dust/Tail End SCR

Mario,

To clarify our conversation about gas to gas heat exchangers (GGH), it is our understanding that for the tail end SCR arrangements a GGH is needed to heat the WFGD outlet air above the saturation temp to avoid acid mist condensation in the SCR GGH.

Due to SO2 emission limits required, the GGH at the WFGD cannot exceed more than a 2% leakage. If this is cannot be achieved then we would require a “no-leak” type GGH at the FGD, possibly one using a heat transfer fluid in a closed-loop or a direct-fired NG burner. Based on your experience with these projects we will default to your assumption as to which type of GGH would be most economically prudent

The use of steam as a heating source, such as a steam coil, is not an option for this site. Thanks,

Christopher Bowman

Subject: RFQ: Low Dust/Tail End SCR

Mario,

As discussed on the phone, Minnkota Power is looking to add an SCR to each existing unit at their Milton R. Young Power Station (MRY). Due to the high sodium content of the coal, we are requesting budgetary equipment quotes of a Low Dust and Tail End SCR arrangement for each unit at MRY. The Low Dust SCR will be located downstream of each units ESP and the Tail End SCR will be located downstream of each units WFGD. The estimated flue gas for each associated option and coal analysis is attached.

General Information:
Unit 1, 257 MWg, cyclone-fired, subcritical, SCR COD December 2010
Unit 2, 477 MWg, cyclone-fired, subcritical, SCR COD December 2011
Fuel: Each unit burns 100% North Dakota Lignite.
Ammonia Reagent: 50% Urea solution
Location: Center, North Dakota – Milton R. Young Station

Each system should be based upon the following components and specifications:

- SCR system w/ gas bypass for maintenance (approx. 12.5% of total gas volume)
- Reactor housing
- Catalyst
- Associated flues and internal flow distribution devices
- Ammonia injection grid
- Hoists and monorails for SCR internal maintenance
- Sonic horns
- Natural gas reheater
- Regenerative gas to gas heat exchanger
- Associated interconnecting piping
- Freight to Center, North Dakota

Provided by others:

  - Ductwork to and from SCR
  - Structural support steel
  - Foundations
  - Electrical equipment and controls
  - Air compressors
  - ID Fans and/or booster fans
  - Urea to Ammonia supply system

Please base each systems design assuming guarantees to be provided for NOx reduction as follows:
SCR Inlet NOx: 0.50 lb/MMBtu
Stack Outlet NOx: 0.075 lb/MMBtu
Heat Input (Max / Min):

  - Unit 1: 2,995 / 2,744 MMBtu/hr
  - Unit 2: 5,158 / 4,885 MMBtu/hr

Information required as soon as possible (estimated):

  - Equipment dimensions and layout requirements
  - Heat exchanger weights
  - Pressure loss for each piece of equipment
  - Ammonia consumption, slip rates, and natural gas consumption

We are requesting budgetary pricing of each system by **June 1st** in present day dollars with breakout of the catalyst pricing. Please let us know if you will be able to meet this deadline.

Thank you for your continued assistance and please call if you have any questions.

Attachments: MRY - Flue Gas Conditions (r2).pdf

To clarify the discrepancy in the flue gas numbers, our numbers were based on the flow to each SCR reactor assuming 2 SCR reactors per unit. Therefore it showed half of the total estimated flow per unit. Attached is an updated flue gas analysis with the total numbers for each unit. Thank you for requesting clarification.

To further explain our numbers we assumed the following in calculations:

Heat Input (MMBtu/hr): Unit 1: 2,955, Unit 2: 5,158
Net Plant Heat Rate (Btu/kWhr): Unit 1: 11,498, Unit 2: 10,813
Percent Excess Air in Boiler: Unit 1: 119%, Unit 2: 128%
Air Heater Leakage: Unit 1: 16%, Unit 2: 8.5%

Please contact me with any questions.

The estimated flue gas for each associated option and coal analysis is attached.

General Information:
Unit 1, 257 MWg, cyclone-fired, subcritical, SCR COD December 2010
Unit 2, 477 MWg, cyclone-fired, subcritical, SCR COD December 2011
Fuel: Each unit burns 100% North Dakota Lignite.
Ammonia Reagent: 50% Urea solution
Location: Center, North Dakota – Milton R. Young Station

Each system should be based upon the following components and specifications:

- SCR system w/ gas bypass for maintenance (approx. 12.5% of total gas volume)
- Reactor housing
- Catalyst
- Associated flues and internal flow distribution devices
- Ammonia injection grid
- Hoists and monorails for SCR internal maintenance
- Sonic horns
- Natural gas reheater
- Regenerative gas to gas heat exchanger
- Associated interconnecting piping
- Freight to Center, North Dakota

Provided by others:

- Ductwork to and from SCR
- Structural support steel
- Foundations
- Electrical equipment and controls
- Air compressors
- ID Fans and/or booster fans
- Urea to Ammonia supply system

Please base each systems design assuming guarantees to be provided for NOx reduction as follows:
SCR Inlet NOx: 0.50 lb/MMBtu
Stack Outlet NOx: 0.075 lb/MMBtu
Heat Input (Max / Min):

- Unit 1: 2,995 / 2,744 MMBtu/hr
- Unit 2: 5,158 / 4,885 MMBtu/hr

<u>Information required as soon as possible (estimated):</u>

- Equipment dimensions and layout requirements
- Heat exchanger weights
- Pressure loss for each piece of equipment

- Ammonia consumption, slip rates, and natural gas consumption

We are requesting budgetary pricing of each system by **June 1st** in present day dollars with breakout of the catalyst pricing. Please let us know if you will be able to meet this deadline.

Thank you for your continued assistance and please call if you have any questions.

Chris,

RE: Tail-end SCR

How much leakage can the unit(s) accept across the FGD heat recovery GGH? This would ultimately affect the SO2 removal efficiency of the absorber(s). The leakage specification greatly affects the overall cost.

To clarify the discrepancy in the flue gas numbers, our numbers were based on the flow to each SCR reactor assuming 2 SCR reactors per unit. Therefore it showed half of the total estimated flow per unit. Attached is an updated flue gas analysis with the total numbers for each unit. Thank you for requesting clarification.

To further explain our numbers we assumed the following in calculations:

Heat Input (MMBtu/hr): Unit 1: 2,955, Unit 2: 5,158
Net Plant Heat Rate (Btu/kWhr): Unit 1: 11,498, Unit 2: 10,813
Percent Excess Air in Boiler: Unit 1: 119%, Unit 2: 128%
Air Heater Leakage: Unit 1: 16%, Unit 2: 8.5%

Please contact me with any questions.

Chris,

I've included a summary table below that compares the flue gas conditions we get form our combustion program vs. the table in the RFQ below giving the heat input for U2 and the coal HHV. As you can see they don't match up well, so we'll need some clarification.

Chris,

We can meet the following dates for the information you requested:

April 17th
Equipment dimensions and layout requirements
Heat exchanger weights

May 1st
Pressure loss for each piece of equipment
Ammonia consumption, slip rates, and natural gas consumption

We will try to improve the April 17th date.

Subject: RFQ: Low Dust/Tail End SCR

Mario,

As discussed on the phone, Minnkota Power is looking to add an SCR to each existing unit at their Milton R. Young Power Station (MRY). Due to the high sodium content of the coal, we are requesting budgetary equipment quotes of a Low Dust and Tail End SCR arrangement for each unit at MRY. The Low Dust SCR will be located downstream of each units ESP and the Tail End SCR will be located downstream of each units WFGD. The estimated flue gas for each associated option and coal analysis is attached.

General Information:
Unit 1, 257 MWg, cyclone-fired, subcritical, SCR COD December 2010
Unit 2, 477 MWg, cyclone-fired, subcritical, SCR COD December 2011
Fuel: Each unit burns 100% North Dakota Lignite.
Ammonia Reagent: 50% Urea solution
Location: Center, North Dakota – Milton R. Young Station

Each system should be based upon the following components and specifications:

- SCR system w/ gas bypass for maintenance (approx. 12.5% of total gas volume)
- Reactor housing
- Catalyst
- Associated flues and internal flow distribution devices
- Ammonia injection grid
- Hoists and monorails for SCR internal maintenance
- Sonic horns
- Natural gas reheater
- Regenerative gas to gas heat exchanger
- Associated interconnecting piping
- Freight to Center, North Dakota

Provided by others:

- Ductwork to and from SCR
- Structural support steel
- Foundations
- Electrical equipment and controls
- Air compressors
- ID Fans and/or booster fans
- Urea to Ammonia supply system

Please base each systems design assuming guarantees to be provided for NOx reduction as follows:
SCR Inlet NOx: 0.50 lb/MMBtu
Stack Outlet NOx: 0.075 lb/MMBtu
Heat Input (Max / Min):

- Unit 1: 2,995 / 2,744 MMBtu/hr
- Unit 2: 5,158 / 4,885 MMBtu/hr

<u>Information required as soon as possible (estimated):</u>

- Equipment dimensions and layout requirements
- Heat exchanger weights
- Pressure loss for each piece of equipment
- Ammonia consumption, slip rates, and natural gas consumption

We are requesting budgetary pricing of each system by **June 1st** in present day dollars with breakout of the catalyst pricing. Please let us know if you will be able to meet this deadline.

To: 'MGialanella@babcockpower.com'
Cc: 'bbasile@babcockpower.com'; Blackwood, Dave
Subject: RE: Low Dust/Tail End SCR

Mario,

To clarify our conversation about gas to gas heat exchangers (GGH), it is our understanding that for the tail end SCR arrangements a GGH is needed to heat the WFGD outlet air above the saturation temp to avoid acid mist condensation in the SCR GGH.

Due to SO2 emission limits required, the GGH at the WFGD cannot exceed more than a 2% leakage. If this is cannot be achieved then we would require a “no-leak” type GGH at the FGD, possibly one using a heat transfer fluid in a closed-loop or a direct-fired NG burner. Based on your experience with these projects we will default to your assumption as to which type of GGH would be most economically prudent

The use of steam as a heating source, such as a steam coil, is not an option for this site. Thanks,

Christopher Bowman

Subject: RE: FW: Comments to SCR Technology at MRYS Units 1&2

Wayne -

Thank you for your willingness to meet with Minnkota, Burns & McDonnell, and University of North Dakota on Monday afternoon, August 10th.

The purpose of this visit is to introduce the members of the project team, and to discuss Haldor Topsoe's experience with SCR catalyst and how it may relate to this application. One of our objectives for this project is to establish expected catalyst volumes and deactivation rates for exposure to flue gases produced by cyclone boilers firing North Dakota lignite at Milton R. Young Station as part of a cost study for low dust and tail end SCR technologies.

The current plans for the trip and visit are as follows:

We will fly on Minnkota's turboprop aircraft departing from near Kansas City, Missouri in the morning, arriving around noon at the Hobby airport (alternate: Ellington field, which is closer to HT's office).

We expect to arrive at Haldor Topsoe's office shortly after 1 pm, allowing for travel from the airport and a quick lunch on the way. We will confirm the estimated arrival time prior to departure.

The meeting is anticipated to take approximately 2 hours, so we expect to depart between 3:00 and 3:30 pm to return to the airport. We will fly back to Kansas City late Monday afternoon.

We currently expect 7 people to visit and participate in this discussion:
> Ron Bryant, Burns & McDonnell project manager for Minnkota air pollution control projects
> Carl Weilert, Burns & McDonnell principal engineer for powerplant air pollution control projects
> Robert Blakley, Burns & McDonnell project engineer for Minnkota's NOx reduction program
> Luther Kvernen, Minnkota Vice President of Generation, Grand Forks, North Dakota headquarters
> John Graves, Minnkota Environmental Manager, Grand Forks, North Dakota headquarters
> Andy Freidt, Minnkota Permit and Compliance Engineer, Milton R. Young Station, Center, North Dakota
> Steven Benson, PhD, Professor, Department of Chemical Engineering at University of North Dakota, Grand Forks, ND, and President, Microbeam Technologies, Inc.

You advised this morning (Monday, 8/3) that you will be out of the office until mid-day Thursday, 8/6. We will confirm any updates in schedules and arrangements Thursday afternoon or Friday morning.

If you have any questions, please advise.

Thanks,

Bob Blakley

Subject RE: FW: Comments to SCR Technology at MRYS Units 1&2

Wayne -

Minnkota, BMcD, and UND accept your lunch invitation and suggestion for the local airport.

Minnkota's pilot will plan on flying and landing at Ellington field, Southwest Airport Services. Minnkota will arrange for local transportation at Ellington field.

Just let me know where you'll be meeting us for lunch, and we will plan on arriving there shortly after noon on Monday, August 10th.

We will advise on the agenda in the next day or two.

Bob Blakley

Bob,

Ellington Field is closer, about 10-15 minutes away. Since you are flying a private plane you can probably use Southwest

Services who is the main flying service at Ellington.

Also Nate and I would like to take y'all to lunch if possible. We can talk later in the week and work out the details.

Thanks,
Wayne

Subject RE: FW: Comments to SCR Technology at MRYS Units 1&2

Wayne -

Thank you for your willingness to meet with Minnkota, Burns & McDonnell, and University of North Dakota on Monday afternoon, August 10th.

The purpose of this visit is to introduce the members of the project team, and to discuss Haldor Topsoe's experience with SCR catalyst and how it may relate to this application. One of our objectives for this project is to establish expected catalyst volumes and deactivation rates for exposure to flue gases produced by cyclone boilers firing North Dakota lignite at Milton R. Young Station as part of a cost study for low dust and tail end SCR technologies.

The current plans for the trip and visit are as follows:

We will fly on Minnkota's turboprop aircraft departing from near Kansas City, Missouri in the morning, arriving around noon at the Hobby airport (alternate: Ellington field, which is closer to HT's office).

We expect to arrive at Haldor Topsoe's office shortly after 1 pm, allowing for travel from the airport and a quick lunch on the way. We will confirm the estimated arrival time prior to departure.

The meeting is anticipated to take approximately 2 hours, so we expect to depart between 3:00 and 3:30 pm to return to the airport. We will fly back to Kansas City late Monday afternoon.

We currently expect 7 people to visit and participate in this discussion:

> Ron Bryant, Burns & McDonnell project manager for Minnkota air pollution control projects
> Carl Weilert, Burns & McDonnell principal engineer for powerplant air pollution control projects
> Robert Blakley, Burns & McDonnell project engineer for Minnkota's NOx reduction program
> Luther Kvernen, Minnkota Vice President of Generation, Grand Forks, North Dakota headquarters
> John Graves, Minnkota Environmental Manager, Grand Forks, North Dakota headquarters
> Andy Freidt, Minnkota Permit and Compliance Engineer, Milton R. Young Station, Center, North Dakota
> Steven Benson, PhD, Professor, Department of Chemical Engineering at University of North Dakota, Grand Forks, ND, and President, Microbeam Technologies, Inc.

You advised this morning (Monday, 8/3) that you will be out of the office until mid-day Thursday, 8/6. We will confirm any updates in schedules and arrangements Thursday afternoon or Friday morning.

If you have any questions, please advise.

Thanks,

Bob Blakley

Bob,

It was nice talking with you this morning. We will plan on meeting with you and the folks from Minnkota and the University of North Dakota on Monday afternoon August 10th in our office's in Houston, Texas. Our address is: 17629 El Camino Real, Houston, TX 77058, Suite 300. Please let me know what time we should expect you as you are able to firm thing up.

Regards,
Wayne

DRAFT #2 – HALDOR TOPSOE

MINNKOTA – MRY STATION SCR COST STUDY MEETING

Monday, August 10, 2009
1:00 PM
Meeting Location: Haldor Topsoe, Inc., Houston, Texas

Meeting Participants:

Haldor Topsoe, Inc.

- Wayne Jones, Sales Manager, Power Generation (Houston)
- Nathan White, Senior Account Executive (Houston)
-

Minnkota Power Cooperative, Inc.

- Luther Kvernen, Vice President - Generation (Grand Forks Headquarters)
- John Graves, Environmental Manager (Grand Forks Headquarters)
- Andy Freidt, Permit and Compliance Engineer (MRY Station)

University of North Dakota and Microbeam Technologies

- Steven Benson, PhD, Professor, Department of Chemical Engineering at University of North Dakota and President, Microbeam Technologies, Inc

Burns & McDonnell

- Ron Bryant, Burns & McDonnell project manager for Minnkota air pollution control projects
- Carl Weilert, Burns & McDonnell principal engineer for powerplant air pollution control projects
- Robert Blakley, Burns & McDonnell project engineer for Minnkota's NOx reduction program

Meeting Purpose:

1. To develop a common understanding of the purpose, unique challenges and status of Minnkota's cost study for low dust and tail end SCR technologies.
2. Discuss Haldor Topsoe's experience with SCR catalyst and how it may relate to the application of high sodium and potassium aerosols associated with the combustion of ND lignite in cyclone fired boilers.

AGENDA

1. Introductions

2. Review Meeting Purpose and Agenda

3. Minnkota/MRY Station Background – Luther Kvernen (10 minutes)

- Organization
- SCR cost study

4. ND Lignite (Center Mine) Characteristics – Steve Benson (10 minutes)

5. SCR cost study – Burns & McDonnell (designate) (10 minutes)

- Impact of catalyst volumes and deactivation rates
    - ➢ Input requirements to provide reasonable cost estimates

6. Haldor Topsoe Background – ___________ (10 minutes)

- Organization
- Experience with SCR catalyst for this type of application

7. Identify specific questions/concerns -- All

8. Exploration of opportunities – All

9. Action items

10. Other

Hello Ron,

One change to your agenda. I am no longer a Senior Account Executive. I am Director, Business Development. We re-organized the SCR/DeNOx Catalyst & Technology side of HTI back in February, 2009. We will explain our new organization and responsibilities to you when we see you Monday.

Best regards,
Nathan White

MINNKOTA – MRY STATION SCR COST STUDY MEETING

Monday, August 10, 2009
1:00 PM
Meeting Location: Haldor Topsoe, Inc., Houston, Texas

Meeting Participants:

Haldor Topsoe, Inc.
- Wayne Jones, Sales Manager, Power Generation (Houston)
- Nathan White, Director, Business Development (Houston)

Minnkota Power Cooperative, Inc.
- Luther Kvernen, Vice President - Generation (Grand Forks Headquarters)
- John Graves, Environmental Manager (Grand Forks Headquarters)
- Andy Freidt, Permit and Compliance Engineer (MRY Station)

University of North Dakota and Microbeam Technologies
- Steven Benson, PhD, Professor, Department of Chemical Engineering at University of North Dakota and President, Microbeam Technologies, Inc

Burns & McDonnell
- Ron Bryant, Burns & McDonnell project manager for Minnkota air pollution control projects
- Carl Weilert, Burns & McDonnell principal engineer for powerplant air pollution control projects
- Robert Blakley, Burns & McDonnell project engineer for Minnkota's NOx reduction program

Meeting Purpose:

1. To develop a common understanding of the purpose, unique challenges and status of Minnkota's cost study for low dust and tail end SCR technologies.
2. Discuss Haldor Topsoe's experience with SCR catalyst and how it may relate to the application of high sodium and potassium aerosols associated with the combustion of ND lignite in cyclone fired boilers.

AGENDA

1. Introductions

2. Review Meeting Purpose and Agenda

3. Minnkota/MRY Station Background – Luther Kvernen (10 minutes)
- Organization
- SCR cost study

4. ND Lignite (Center Mine) Characteristics – Steve Benson (10 minutes)

5. SCR cost study – Burns & McDonnell (10 minutes)
- Impact of catalyst volumes and deactivation rates
    - Input requirements to provide reasonable cost estimates

6. Haldor Topsoe Background – (10 minutes)
- Organization
- Experience with SCR catalyst for this type of application

7. Identify specific questions/concerns – All

8. Exploration of opportunities – All

9. Action items

10. Other

MINNKOTA – MRY STATION SCR COST STUDY MEETING

Tuesday, August 11, 2009
9:00 AM
Meeting Location: Burns & McDonnell with CERAM Environmental, Inc.

Meeting Participants:

CERAM Environmental, Inc.

- Noel Rosha, Senior Applications Engineer (Kansas City)
- Dr. Greg Holscher, Senior Applications Engineer (Kansas City)
- Jim Ferrigan, CRF Environmental, Inc. Sales Representative (Kansas City)

Minnkota Power Cooperative, Inc.

- Luther Kvernen, Vice President - Generation (Grand Forks Headquarters)
- John Graves, Environmental Manager (Grand Forks Headquarters)
- Andy Freidt, Permit and Compliance Engineer (MRY Station)

University of North Dakota and Microbeam Technologies

- Steven Benson, PhD, Professor, Department of Chemical Engineering at University of North Dakota and President, Microbeam Technologies, Inc

Burns & McDonnell

- Ron Bryant, Burns & McDonnell project manager for Minnkota air pollution control projects
- Carl Weilert, Burns & McDonnell principal engineer for powerplant air pollution control projects
- Robert Blakley, Burns & McDonnell project engineer for Minnkota's NOx reduction program

Meeting Purpose:

1. To develop a common understanding of the purpose, unique challenges and status of Minnkota's cost study for low dust and tail end SCR technologies.
2. Discuss CERAM Environmental, Inc. experience with SCR catalyst and how it may relate to the application of high sodium and potassium aerosols associated with the combustion of ND lignite in cyclone fired boilers.

AGENDA

1. Introductions

2. Review Meeting Purpose and Agenda

3. Minnkota/MRY Station Background – Luther Kvernen (10 minutes)

Subject: Minnkota MR Young Presentation
Attachments: Low Dust & Tail End 2009 Reference List.pdf; Minnkota MR Young Presentation at B&McD 090811.pdf

Ron,

Attached, please find a copy of our presentation from the meeting with Minnkota this week. I have also included our low dust/tail end experience list. Thanks again for the opportunity to meet with everyone to discuss this unique project.

Best regards

Noel Rosha, P.E.
Applications Engineer

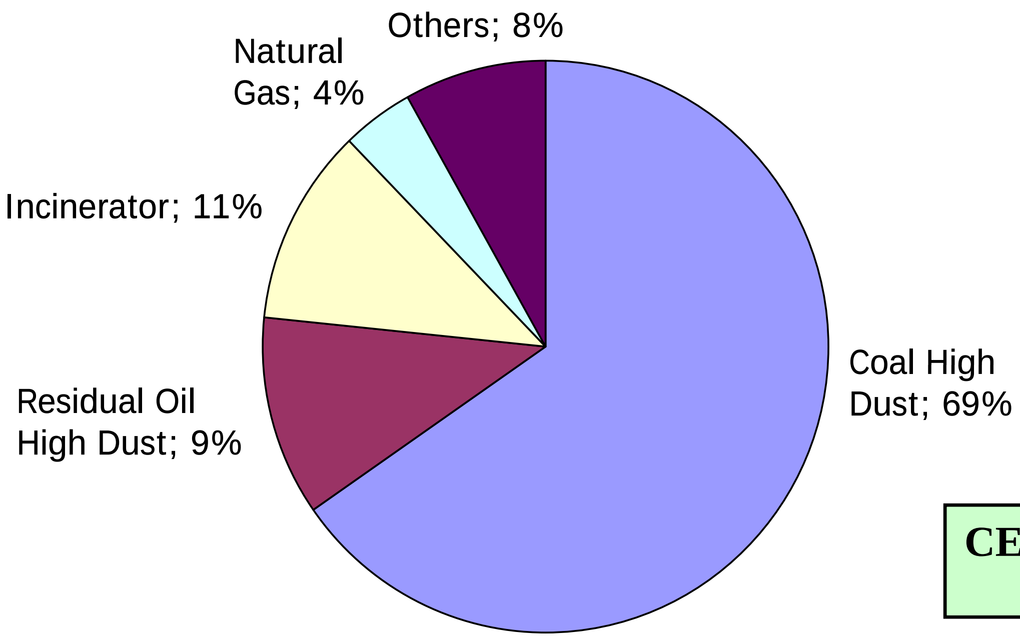
CERAM Has Completed More Than 400 Dirty Fuel Based SCR Catalyst Supply Projects

- Bituminous Coal
- Sub-Bituminous Coal
- Brown (Lignite) Coal
- Distillate Fuel Oil
- Residual Fuel Oil
- Biomass
- Petroleum Coke
- Orimulsion
- Synthesis Gas
- Chemical Weapons
- Wood, Wood Waste and Peat
- Municipal Solid Waste
- Refuse Derived Fuel
- Industrial, Hospital, and Hazardous Waste Incinerators
- Ethylene Crackers, HNO3, and FCC Units
- Blast Furnace and Coke Oven Gas
- Steel Production and Pickling
- Glass Production Plants
- Natural Gas



CERAM's Experience Portfolio Focus' on Dirty Gas Applications

CERAM Catalyst Designs for ND Lignite Ash

- High Sodium Concentrations in Ash
  - Sodium Aerosols are a Known Catalyst Poison
  - Critical to Consider Sodium Aerosols Present Downstream of ESP and Wet FGD
  - May Require Special Layup Protection
- Presence of Potassium in Ash
  - Similar to Biomass Applications, can be Accounted for in Catalyst Design Margin
- Presence of Pyrosulfates (Sodium, Iron, and Sulfur)
  - Can Cause Increase in SO_2 to SO_3 Conversion Rate Over Time
  - Concern Reduced with Low Dust or Tail End SCR
  - Can be Accounted for In Catalyst Design Margin

CERAM

Subject: Update

Ron,

I have finished the requested document defining HTI "typical" scope of work on similar projects. I should have that to you tomorrow. I'm shooting for our response to the NDA on Wednesday. I have a request in for any information available with respect to the start up of Amager Plant

Thanks,
Wayne

SCR Process Engineering Package
Scope of Work, Responsibilities, Battery Limits and Guarantees

8-14-2009

Haldor Topsoe, Inc. (HTI) has the capability of simply providing SCR catalyst in elements or modules or providing the catalyst along with a comprehensive process engineering package. For coal fired applications, HTI prefers to provide both the catalyst and process engineering package. This structure provides single point responsibility for the client and allows HTI to utilize our vast amount of experience to design a well integrated SCR system from the economizer outlet to the air heater inlet.

Please find a description below of what will be called HTI's "preferred" scope of work when process engineering tasks are included in our scope. With any project where more than one company is involved in the engineering, optimal points exist where it makes the most sense to draw battery limits where one company hands off responsibility to another. I will define these battery limits in detail.

While the primary engineering firm (AE) investigates available space, foundation constraints and structural steel and support requirements for the ducts, flues and reactor box. HTI will assist in the sizing of the reactor to provide the optimal gas velocity for the specific application. In addition, HTI will review preliminary ductwork layout drawings provided by AE to determine if any fatal flaws might exist with regard to meeting or exceeding all required flue gas conditions at the AIG. HTI does this review in coordination with and with the assistance of the flow modeling company, contracted by HTI and also includes an evaluation of the proposed ductwork configuration focusing on conditions that might create ash fallout issues in the ductwork or reactor.

HTI will also develop and provide recommended minimum requirements for all flow criteria that must be validated in the physical flow model paying particular attention to any characteristics of a specific application that might impact SCR system performance. For example, if very high NOx removal is required special attention might be given to NH_3 to NOx maldistribution at the catalyst face while if the fuels are very erosive and contain a high percentage of ash then gas velocity and angle of entry of the flue gas at the catalyst face might be emphasized.

Once the general arrangement is determined, a preliminary CFD model will be produced in parallel with the construction of a 1/12 scale physical model. HTI will work with the flow modeler throughout the construction and initial testing of the model. If early test results indicate problems with the initial ductwork design HTI will work with the AE and flow modeler to make necessary revisions while considering cost and constructability impacts.

Early in the process a decision will be made whether to use HTI's proprietary "Star Mixer" and AIG system or a Sulzer static mixer and their AIG design. If the HTI mixer is used then HTI will provide drawings for both the mixer and AIG assembly that contain all the detail necessary to generate fabrication drawings. In this case, HTI will also provide the design drawings for the support hardware necessary to install the "Star Mixers" and AIG inside the duct. The AE will be responsible for the procurement of the "Star Mixer", AIG and attachment hardware. The AE will also be responsible for designing the nozzle and flange assembly at the duct wall that will provide the penetration and support for the AIG lance to the duct wall. The battery limit on the AIG drawing is at the AIG lance pipe flange just outside the duct work lagging and everything upstream of that point is the responsibility of the AE.

If a Sulzer mixer is selected, then HTI will take on the responsibility of specifying and procuring both the flow model mixers (1/12 scale) and full scale mixers as well as the Sulzer designed AIG. Sulzer will design and supply all attachment and support hardware required for both the AIG assembly and static mixers.

As apart of the flow model effort, drawings will be provided for all flow conditioning devices including, if required, the large particle ash (LPA) screens. The drawings will provide all required information and dimensions to support the generation of fabrication drawings by the AE including location and orientation of the flow conditioning devices within the duct or reactor. The AE will be responsible for the detail design and support of all flow conditioning devices located either in the ductwork or reactor as well as the procurement of all flow conditioning devices except the Sulzer static mixers, attachment hardware and associated AIG assembly, as described above.

In some cases both the HTI "Star Mixer" and Sulzer mixer will be tried in the flow model. Based on preliminary results a final selection will then be made. At that time all remaining physical flow and CFD modeling will be preformed using only the selected mixer and AIG system.

Below is a list of deliverables typically provided with the process engineering package from HTI. Additions or deletions from the list are possible to meet the exact requirements of a particular project:

- Process flow diagram
- Engineering deliverable schedule
- Manufacturing schedule
- Quality program description
- Flow modeling including physical and CFD modeling services and final report
- Specification for catalyst cleaning system equipment
- Review of all engineering drawings related to the SCR system
- Drawings for all flow control devices including LPA screen and rectifier grid (attachment drawings and hardware, by AE)

- Drawings for "Star Mixer", attachment hardware and associated AIG system, issued by HTI

(or)

- Drawings for Sulzer static mixer, attachment hardware and associated AIG system, issued by Sulzer through HTI

- License for use of the “Star Mixer” and AIG system
- SCR catalyst module drawings
- SCR catalyst bed dust deflection and module sealing system drawings
- SCR catalyst module lifting yoke drawings
- Catalyst arrangement plan
- Operating procedures for installation of catalyst and operations of the SCR
- Operating procedure for handling and storage of the catalyst
- Special tools list
- Performance test procedure
- Performance curves

HTI can also provide, if required, the following scope of services.

- P&ID, preliminary
- SCR ammonia control system specification
- Ammonia system specification

The following are the process guarantees that HTI typically provides as a part of the process design package.

- SCR system pressure drop from the economizer outlet to the air heater inlet. More specifically the pressure drop includes all ductwork and reactor box included in the physical flow model. A target pressure drop will be provided prior to the completion of the physical flow model followed by the actual pressure drop guarantee after the model is complete.
- Flue gas velocity maldistribution at the AIG, at the catalyst face, and air heater inlet
- Flue gas temperature maldistribution at the AIG and catalyst face
- NH_3 to NOx maldistribution at the AIG and catalyst face
- Flue gas angle of entry at the catalyst face
- Minimize ash deposition as per the physical flow model
- Catalyst life
- NOx removal efficiency
- Ammonia slip
- Ammonia usage
- SO_2 oxidation rate
- Mercury oxidation rate

Subject: Fw: Startup procedure for Amager Unit 1

Attachments: AMV1 Start-up meeting July 2008.pdf

Ron,

Please find a powerpoint presentation below discussing the proposed startup procedure for Amager 1. They plan to use heated air to preheat the SCR prior to the introduction of flue gas. The stream/gas heater will be used to preheat the air. Let me know if you have any questions.

Regards,
Wayne

Subject Re: Startup procedure for Amager Unit 2Link

Wayne,

Condensing of water during start-up is definitely a serious problem with the high content of Na in the ash.

In Amager 2 this problem is solved by a steam-gas heater, please refer to page 6 in the attached file. The plant is preheated by air and the steam-gas heater just before the SCR gives a "dry" heating of the gas.

Best regards
Torben

Subject Startup procedure for Amager Unit 2

Gentlemen,

We have been discussing with Minnkota Power the possibility of installing a SCR either downstream of a cold ESP or wet scrubber on a North Dakota lignite fired cyclone boiler. As you may recall, this fuel contains a high level of alkali material (as high as 6-9% Na) in the fuel. The fuel also has very high levels of CaO (~20%). The concern is that the high CaO coupled with the high Na will produce a very fine and extremely sticky fly ash. My understanding is that Amager 2 has a tail end SCR. We were discussing possible operational issues surrounding the startup of Amager due to the high levels of alkali poisons in the biomass fuel and whether a full/partial bypass around the SCR may have been installed.

The flue gas on the lignite unit will be reheated using NG or other heat source. During startup if the reactor and catalyst are cold and covered with fly ash the initial flue gas entering the SCR will be rather cool and upon hitting the surface of the catalyst and catalyst modules water is likely to condense on the surface providing a path for the Na to enter the catalyst pore structure. We assumed that Amager might have a similar issue and may have installed a bypass to allow for the heat up of the flue gas before passing it through the reactor.

Any ideas or comments are appreciated.

Thanks,
Wayne

AMV1 Start-up of flue gas cleaning

Meeting with API and HTAS 16.07.2008

Henrik Rostgaard

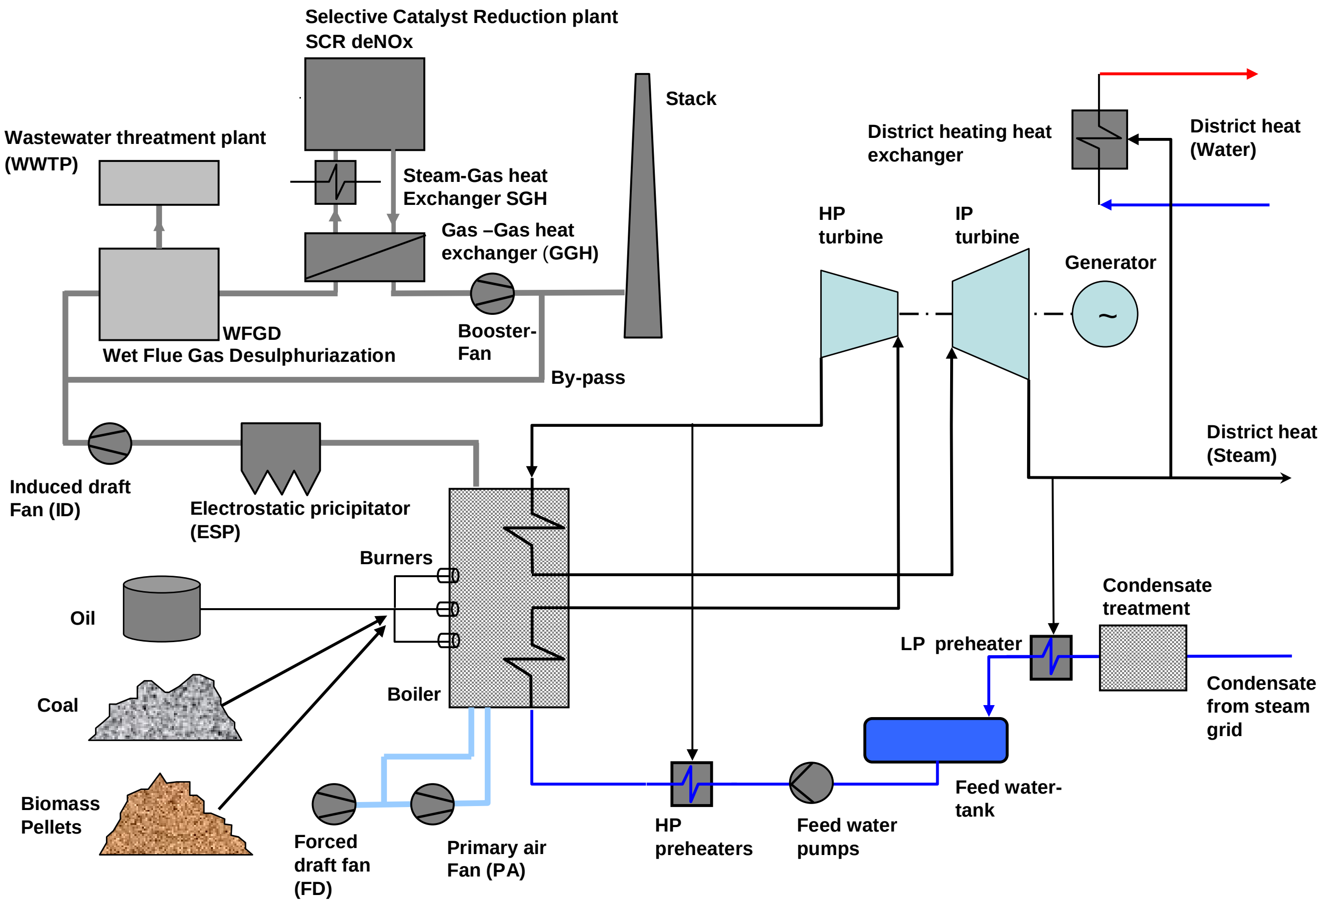
Chemistry & Materials

VATTENFALL

Agenda

1) Presentation
2) Introduction
3) Start and stop of Flue Gas Cleaning
4) Stand still
5) Experience from start up unit 3
6) Discussion and comments from API and HTAS
7) Miscellaneous

Introduction to Amager Power Station unit 1



VATTENFALL

Introduction – fuels and Flue Gas Cleaning

Fuels		
Biomass	–	Flue gas cleaning is not necessary
Coal/biomass	–	Flue gas cleaning will be used
Coal	–	Flue gas cleaning will be used
Oil	–	Only for start-up, but flue gas cleaning will be used if coal-firing is planned

Start and stop of flue gas cleaning

1) Start-cases

Cold start of boiler

Hot start

Shift from biomass to coal

2) Stop-cases

Stop of boiler

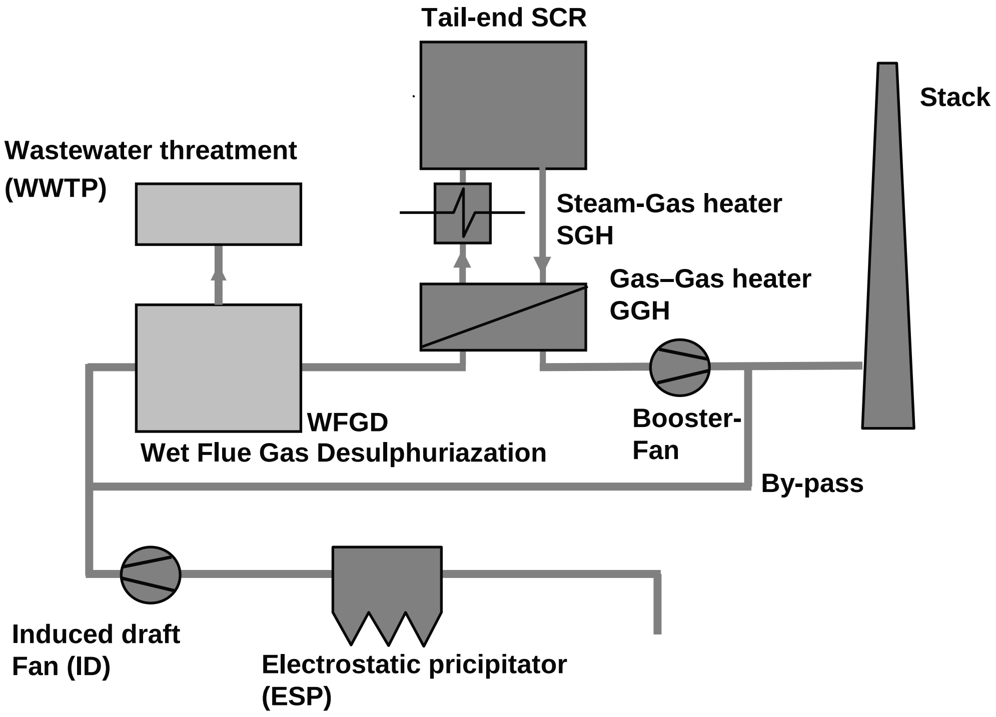
Shift from coal to biomass

3) Stand-still

During biomass-firing

During overhaul and summer-stop

Flue gas cleaning AMV1



Tail-end SCR

Stack

Wastewater threatment (WWTP)

Steam-Gas heater SGH

Gas–Gas heater GGH

WFGD
Wet Flue Gas Desulphuriazation

Booster-Fan

By-pass

Induced draft Fan (ID)

Electrostatic pricipitator (ESP)

Cold start

Boiler, ESP, flue gas ducts, FGD and SCR are pre-heated with air

Heating air before FGD below 45 degree C

Air from the boiler will pass through FGD to the gas/gas heater, steam/gas heater and SCR.

The scrubber liquid is mixed by the hydrocyclone pumps, but the oxidation air is not injected.

The steam/gas heater is operated to give a temperature increase of the SCR of 50 degree C or more pr. hour.

Cold start

Heating air before FGD above 45 degree C

- Oxidation air is injected to start circulation of the scrubber slurry
- SGH is operated to give a temperature increase of the SCR of 50 degree C or more pr. hour.
- When the temperature of the heating air is 110 degree C before FGD <u>and</u> 65 degree C after SCR, the first oilburner will be ignited.
- Subsequently more oilburners will be ignited and the switch to coal-firing will be done as quick as possible.

Cold start

- During both steps the bypass duct will be closed.
- GGH will always be colder than the SCR.
- The above mentioned procedure will ensure that the temperature of the SCR always is above the water dew point.

Hot start

As second part of cold start

Shift from bio-mass to coal

The procedure for the boiler is not finalized:

Maybe a complete stop is necessary – maybe not.

If a complete stop is not needed, preheating of SCR will not be possible, but GGH will always be colder than SCR.

Stops and standstill

Stop of boiler
No problem – flue gas cleaning will be flushed with air during stop procedure

Shift from coal to biomass
Flue gas cleaning could be left with ”old” flue gas during bypass operation of the boiler.

Stand-still
During biomass-firing – Possibly 3 x 1 month
During overhaul and summer-stop – 3 months

Start up unit 3 on 09.07.2008

Subject: Minnkota SCR Catalyst Recommendations

Attachments: Scope of Services 26Aug09.doc; Report 1084 - Particulate - FINAL 8-20-09.pdf; MRY SCR Vendor Query (4-18-07) - Abbreviated.pdf

Wayne

Minnkota Power is requesting recommendations on SCR catalyst design for low-dust and tail-end applications as discussed in your offices on August 10.

Attached are the following documents for your consideration:

1. Scope of Services 26Aug09
2. Report 1084 - Particulate - FINAL 8-20-09
3. MRY SCR Vendor Query (4-18-07) – Abbreviated

The first document summarizes items Minnkota Power is requesting in support of the required BACT.

The second document is flue gas testing data performed at the Milton R. Young Station. This information should be treated confidential.

The third document includes some basic boiler operating parameters and was extracted from the MRY SCR Vendor Query originally transmitted in April of 2007.

Please contact us if you need any additional information or would like to discuss the project.

Thank you for your assistance.
Ron Bryant
816-822-3023

Scope of Services
SCR Catalyst Recommendations

Minnkota Power Cooperative
Milton R Young Station
August 26, 2009

1. Minnkota Power Cooperative (MPC) operates two coal-fired electric generating units at the Milton R. Young Station. Both units are Babcock & Wilcox balanced-draft cyclone fired boilers burning 100% North Dakota lignite coal supplied from an adjacent mine. Unit 1 has a gross design output capacity of 257 MW and was initially placed into commercial service in 1970. Unit 2 has a gross original design output capacity of 477 MW and was initially put into service in 1977. The units are located approximately 40 miles northwest of Bismarck, ND.

2. MPC is performing a SCR cost estimate for both units as part of a NO_X BACT Study required by the North Dakota Department of Health. Because of the unique characteristics of North Dakota lignite, MPC is requesting assistant with SCR catalyst selection and sizing.

3. The scope of services MPC is requesting includes the following for both low dust and tail end SCR applications for both units:

    a. Size the reactors to provide the optimal gas velocity and NO_X reduction for the specific applications.

    b. Provide anticipated guarantees for NO_X reduction for the specific applications. Nominal anticipated NO_X concentration entering the reactors is 0.5 lb/million Btu. Nominal desired maximum NO_X concentration exiting the reactors is 0.05 lb/million Btu.

    c. Provide anticipated guarantees for ammonia usage and ammonia slip for the specific applications. The maximum ammonia slip should not exceed 5 ppm.

    d. Provide anticipated guarantees for catalyst deactivation rate and life (number of operating hours between catalyst replacement). It is desired to have a 3 year interval between catalyst layer change-out. If a 3 year interval is not achievable, provide the longest interval the catalyst vendor is able to guarantee.

    e. Provide budgetary pricing for the recommended catalyst.

    f. Review preliminary ductwork layout drawings to determine if any fatal flaws are apparent.

4. Additional design parameters and flue gas testing results are included as an attachment. It is the intent that Dr. Steve Benson and other team members will discuss the test data and related implications of the catalyst selection and design with the catalyst supplier.

5. Please provide requested items by September 18, 2009.

EXECUTIVE SUMMARY

Particulate sampling was conducted at Minnkota Power Cooperative's Milton R. Young plant to determine the particulate size and composition distribution of samples collected upstream of the ESP, upstream of the wet scrubber, and downstream of the wet scrubber. Emphasis was placed on determining the fate of sodium, potassium, and calcium since these elements can cause significant plugging and deposition problem.

During the testing, operating conditions of the plant were constant and there was no gas bypass. The coal fired during the testing remained relatively consistent. The as-received ash content ranged from 7.73 to 7.89%. Sodium oxide content of the ash ranged from 7.22 to 7.57% and the base-to-acid ratio decreased the last two days of testing (a result of a decrease in CaO content and an increase in SiO_2 and Al_2O_3 levels). Sampling upstream of the ESP and scrubber were conducted using a combination multicylones and impactors. The cyclones collected sized fractions of larger particles (greater than one to five microns) and the impactor collected the sub-micron particulate. Sampling downstream of the scrubber was conducted with a single cyclone followed by a 13-stage advanced impactor. In addition, the submicron particle number concentration was measured using a scanning mobility particle sizer (SMPS).

The results of the particulate mass information indicated a high loading at the ESP inlet of 4.96×10^6 µg/dscm, a scrubber inlet loading of 1.1×10^4 µg/dscm, and a scrubber outlet loading of 1.08×10^4 µg/dscm. These results show very little overall removal of the submicron particulate across the wet scrubber system. A significant fraction of the particulate was removed by the ESP, with a removal efficiency of 99.76%.

The size distribution of the particulate collected upstream of the ESP and upstream of the scrubber was multi-modal as summarized below:

- Upstream of the ESP there were at least three modes – a larger mode at 40 to 50 µm, a second mode at just under 10 µm, and third mode at about 1 µm. The larger particles are typically derived from mineral grains in the coal such as quartz, clays, and pyrite. The intermediate-sized particles are typically derived from small minerals and organically associated elements. The smaller mode (about one-micron and smaller) contains fine particles and condensed vapor phase species.
- Upstream of the scrubber there were two distinct modes – a larger mode between 8 to 10 µm and another mode centered at about 1 to 2 µm in diameter. The smaller mode is typically condensed vapor phase and small particles.
- Downstream of the scrubber, the primary mode centered at about 0.5 to 0.7 µm, and another possible mode occurred at 3 µm and larger.
- Particle number distributions were as follows:
  - Inlet to the ESP – between 1×10^7 to 10^8 particles per dry normal cubic centimeter (dncc);
  - Inlet to the scrubber is 10^5 particles/dncc;
  - Outlet of the scrubber 7×10^5 particles/dncc.

- Particle number distributions into the nanometer scale (1 µm = 1000 nm) was found to be as high as 10^5 particles/dncc.

Particle composition distributions of the particulate were determined for each of the major elements. The results were reported as µg/dscm of the element as illustrated in the Appendix and in the figures in the text.

- Upstream of the ESP the composition trends for sodium, potassium, calcium and sulfur showed greater concentrations of these elements in the particles that are smaller than 10 µm, with a significant increase in concentration in the flue gas at a particle size of less than 2 µm. There is another increase at 0.1 µm.
- Upstream of the scrubber the compositional trends for sodium, potassium, calcium and sulfur show higher levels at the 1 µm level. The ESP was effective in removing larger-sized particles, as well as some of the 0.1 µm particles. However, in the intermediate 1 µm particles, the ESP is not as effective in removing the particles.
- Downstream of the scrubber the composition size distribution determined for sodium, potassium, calcium and sulfur showed significant levels of sodium and sulfur in size fraction finer than 1 µm. The DLPI sampling system provides very accurate sizing data in the submicron size range. Other elements such as aluminum, silicon and iron show a significant depletion below 1 µm.

Comparison of the characteristics of the particles in terms of mass and composition indicate that, at the time of the testing, the total average mass of the particulate was about 10,800 µg/dscm. The particulate consisted mainly of sodium, potassium, and sulfur. The total quantity of sodium and potassium exiting was between 2000 to 3000 µg/dscm.

INTRODUCTION AND BACKGROUND

Microbeam Technologies, Inc. (MTI) teamed with Energy & Environmental Research Center (EERC) and the Chemical Engineering Department at the University of North Dakota (UND-ChE) to determine the abundance and composition of particulate materials produced at Unit #2 of Minnkota Power Cooperative's Milton R. Young Station (MRY), equipped with an electrostatic precipitator (ESP) and a wet flue gas desulfurization (FGD) system.

Very small particles or aerosols are produced upon combustion of all fuels. These particles have diameters less than ten microns, and in many cases less than one micron. They are formed during the combustion process - when the fuel is exposed to high temperatures and gaseous environments, impurities within the fuel are vaporized. When the gas is cooled, the vaporized species condense to form the small particles or aerosols.

Abundance and composition of the aerosols vary depending upon the fuel type and the combustion system. High-temperature combustion systems, such as cyclone-fired systems, produce higher levels of vaporized species than other combustion system types. Fuels (such as biomass or lignite) that contain high levels of alkali (sodium and potassium) and alkaline earth elements (calcium and magnesium) are especially likely to produce abundant aerosols in the cooler regions of combustion systems, such as air pollution control systems.

Collection of aerosol particles finer than five- to ten-microns in electrostatic precipitators and scrubbers is difficult because physical processes used by these technologies to capture particles are very limited in the one-tenth to five-micron size range. Detailed discussion of the processes can be found in the appendix of this report.

This report contains the results of analyses performed on coal and ash samples collected during field testing at MRY Unit 2. The work was performed to determine the properties (including size, mass, and composition) of particulates collected upstream and downstream electrostatic precipitator and wet FGD.

GOALS AND OBJECTIVES

Objectives of the project were as follows: 1) obtain representative, size-segregated samples of particulate material, including super- and sub-micron particulate, from three locations; 2) perform analyses on these samples to determine the size, mass, and composition distribution; and 3) provide an assessment of the probable impact of particulate inorganic species on the performance of NO_x reduction technologies.

SAMPLE COLLECTION AND CHARACTERIZATION

Sampling

Particulate material in the flue gas was collected and measured upstream and downstream of the MRY electrostatic precipitator, also denoted as the "air heater inlet" and at the wet flue gas desulfurization (FGD) or "scrubber inlet". Multi-cyclone samples were taken at the locations during the impactor testing. Sampling at the ESP inlet and scrubber inlet were conducted at single port locations and traversed for depth. The sampling at the ESP inlet was performed using two different ports; the total sampling time was divided equally between the selected sampling depths. The sampling depths, along with a summary of sampling activities, are summarized in **Table 1**. Sampling locations are shown on a simplified schematic in **Figure 1**.

Multicyclone Sampling

Size-fractionated fly ash samples were collected with a Southern Research Institute multi-staged multi-cyclone placed in the duct work at the air heater inlet (ESP inlet). The multicyclone consists of five cyclones, with decreasing d50 cut points, placed in series. The d50 particle size for each test is determined by the temperature and gas flow rate through the cyclone. For the testing at the MRY station, three of the five cyclone stages were used, along with the impactor, to collect selected coarser and finer fractions simultaneously. Size cut data for the multicyclone sampling performed at the air heater inlet are shown in **Table 2**.

Impactor Sampling

Size-fractionated fly ash samples were collected with a University of Washington seven-stage impactor placed in the gas stream behind the three multi-cyclone stages at the ESP inlet, and was used without multi-cyclone stages at the ESP outlet/scrubber inlet sampling location. The impactor is a round hole, multiple jet-type impactor with seven stages and a backup filter. Each stage has a decreasing d50 cut point. The d50 particle sizes for each test are determined by temperature and gas flow rate through the impactor. Cut points for the impactor at the air heater inlet are shown in **Table 2**. Cut points for the impactor at the scrubber inlet are shown in **Table 3**.

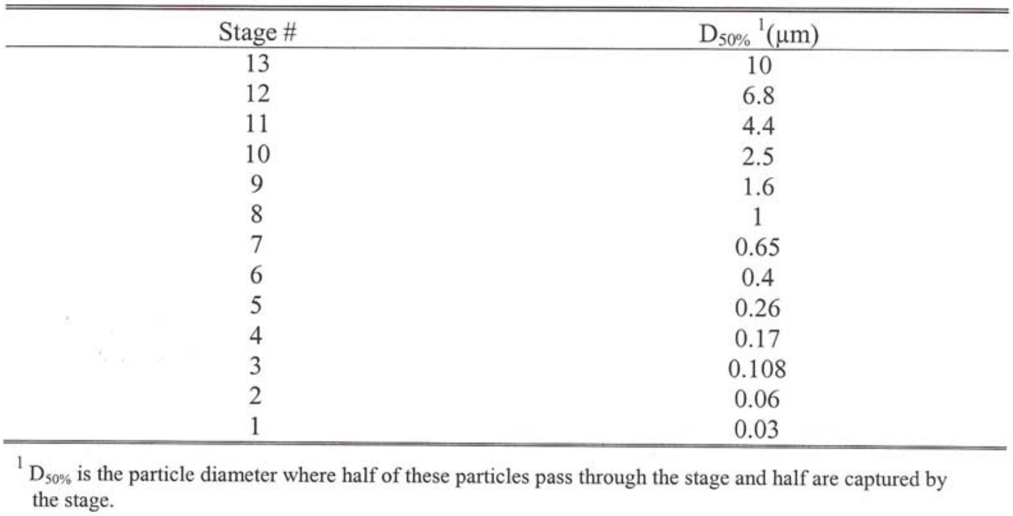
DLPI Sampling

The Dekati Low Pressure Impactor (DLPI) is a state-of-the-art 13-stage cascade impactor for measuring gravimetric particle size distribution of very small particles. It size-classified particles from 10 microns (µm) to 30 nm, and a filter stage accessory enables collection of particles smaller than 30 nm in diameter. **Figure 2** shows the impactor and stages. The d50 cut points for sampling with the DLPI are shown in **Table 4**.

Figure 2. Dekati Low-Pressure Impactor.

Table 4. D50 cut points for sampling (Dekati Low Pressure Impactor) at the B scrubber outlet.



Stage #	$D_{50\%}$ [1](μm)

7	0.65
6	0.4
5	0.26
4	0.17
3	0.108
2	0.06
1	0.03

[1] $D_{50\%}$ is the particle diameter where half of these particles pass through the stage and half are captured by the stage.

SMPS Sampling

Sampling at the scrubber outlet was conducted utilizing the scanning mobility particle scanning (SMPS) system that consists of an electrostatic classifier (EC), a condensation particle counter (CPC), and data analysis center (DAC). A schematic of the system is shown in **Figure 3**. The EC classifies the particles, and the concentration is measured by the CPC. The DAC includes a personal computer with custom software, which controls individual instruments and performs data reduction. The components of the SMPS system, particularly the CPC, function normally at about 35°C (95°F). However, the EC does not appear to be too sensitive to temperature conditions.

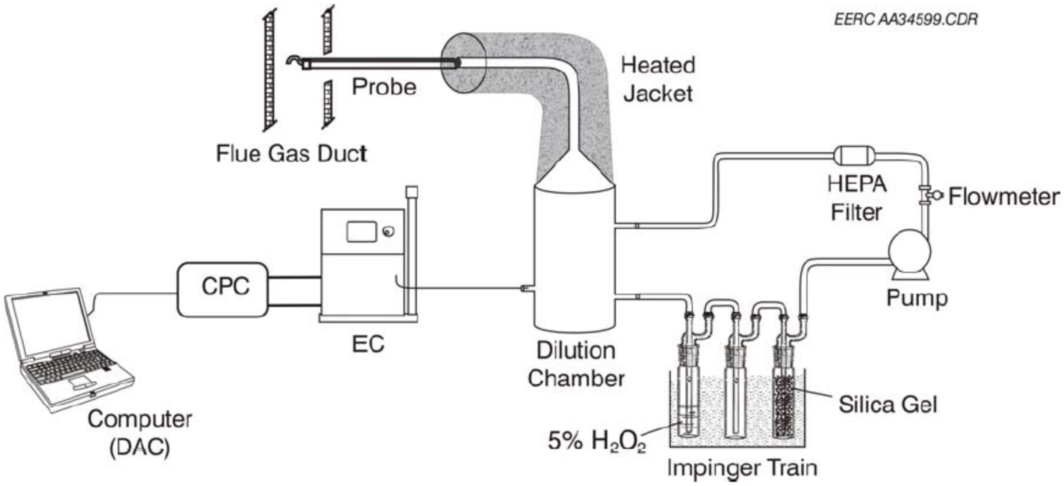

Figure 3. Schematic of the scanning mobility particle scanning (SMPS) system used at the B scrubber outlet.

The procedure for making particulate measurements with the SMPS system is conceptually simple, although manipulating the entire system is quite complex. Typically, flue gas enters the dilution chamber and is mixed with excess air fed through an external pump and at the flow rate of about 45–50 liters per minute (lpm). Dilution air from the pump passes through a HEPA filter to remove any particles that may be in the air. Part of the dilution air is sucked back from the dilution chamber and passed through an impinger train; the wet impinger contains about 250 milliliters (mL) of a 5% hydrogen peroxide (H_2O_2) solution, and the air is dried by passing it through a silica gel flask. The air from the flask is circulated through the pump back to the dilution chamber, and the recirculation process continues for the duration of the measurement. At the bottom of the dilution chamber, a ¼-inch line extracts a sample of the diluted flue gas and delivers it to the EC. The flow rates and pressure drop used in the EC are shown in **Table 5**.

Table 5. Electrostatic classifier (EC) flow meter set points.

Parameter	Monodisperse Air	Sheath Air	Excess Air
Flow Rate, lpm	0.3	3	3
Output, volts	2.305	2.735	2.627
Pressure Drop, cm H_2O	9	N/A*	N/A

* Not applicable.

Measurement does not begin until the CPC is running normally and flow is stable. At a typical working temperature of about 35°C (95°F), indicator lights are checked to ensure all parts are functioning properly (including the liquid level, laser, optics, pump flow, condenser, and saturator). The liquid used in running the CPC is n-butyl alcohol (n-butanol).

Analysis

Table 6 contains a full list of the samples collected and analyses performed. Samples collected were analyzed to determine chemical composition. Scanning electron microscopy with x-ray elemental analysis was performed on the ash samples. Information gained from this method included images and point and area (average) analyses. This type of analysis is called "morphology" because it combines image analysis for features of interest with chemical analysis.

The multicyclone samples were analyzed using bulk chemical anlaysis at EERC. The bulk analysis involved microwave digestion of the ash followed by inductively-coupled plasma-mass spectrometry (ICP-MS). Concentrations of the major elements sodium, potassium, phosphorus, calcium, magnesium and iron were determined.

The coal samples collected during the tests were composited for standard ASTM tests (proximate and ash composition or "mineral ash" analysis) and for computer-controlled scanning electron microscopy (CCSEM) analysis, which provides information on mineral types, abundance, and sizes within the coal.

RESULTS AND DISCUSSION

Coal Analysis and Plant Operating Conditions during Testing

The coal samples for each day were composited to form one larger sample; the four resulting composite coal samples were subjected to proximate and ash composition analyses. The results of the analyses are shown in **Table 7**. The coal was relatively consistent over the time period sampled. The as-received ash content ranged from 7.73 to 7.89%. Sodium content ranged from 7.22 to 7.57% and the base-to-acid ratio decreased the last two days of testing as a result of a decrease in CaO content and an increase in SiO_2 and Al_2O_3 levels.

Table 7. Proximate and ash composition analyses for four composite coal samples taken from MRY coal feeders on March 16 through 19, 2009.

Figures 4 and **5** show the overall coal flow rate, along with the ash quantity and base-to-acid ratio determined with the Full-Stream Elemental Analyzer (FSEA) during the test period. The FSEA data was corrected for a 23-hour lag time between filling the hoppers and feeding coal to the cyclones. These data show a decrease in the base-to-acid ratio during the testing period. This was observed in the analysis of the four daily composite samples.

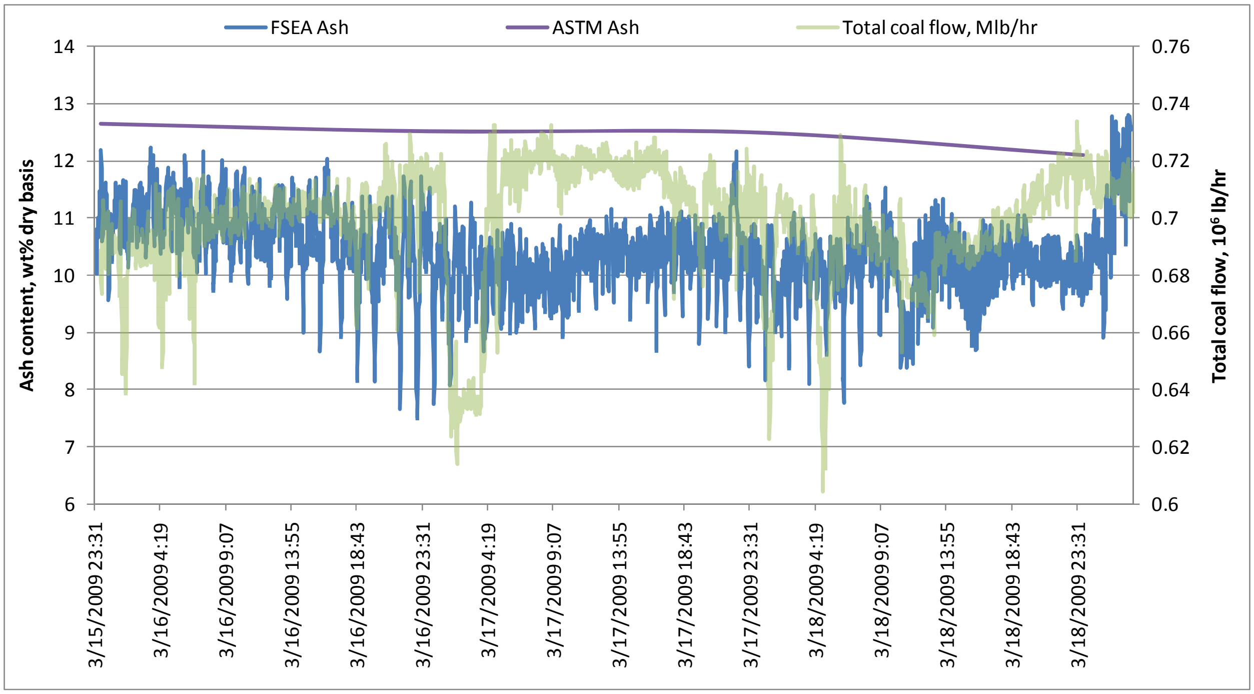

Figure 4. Coal belt flow and fuel ash quantity (determined with FSEA and by ASTM method on composite coal samples) during the testing. The FSEA data was corrected for a 23-hour lag time between filling the hoppers and estimated fuel fed to the cyclones.

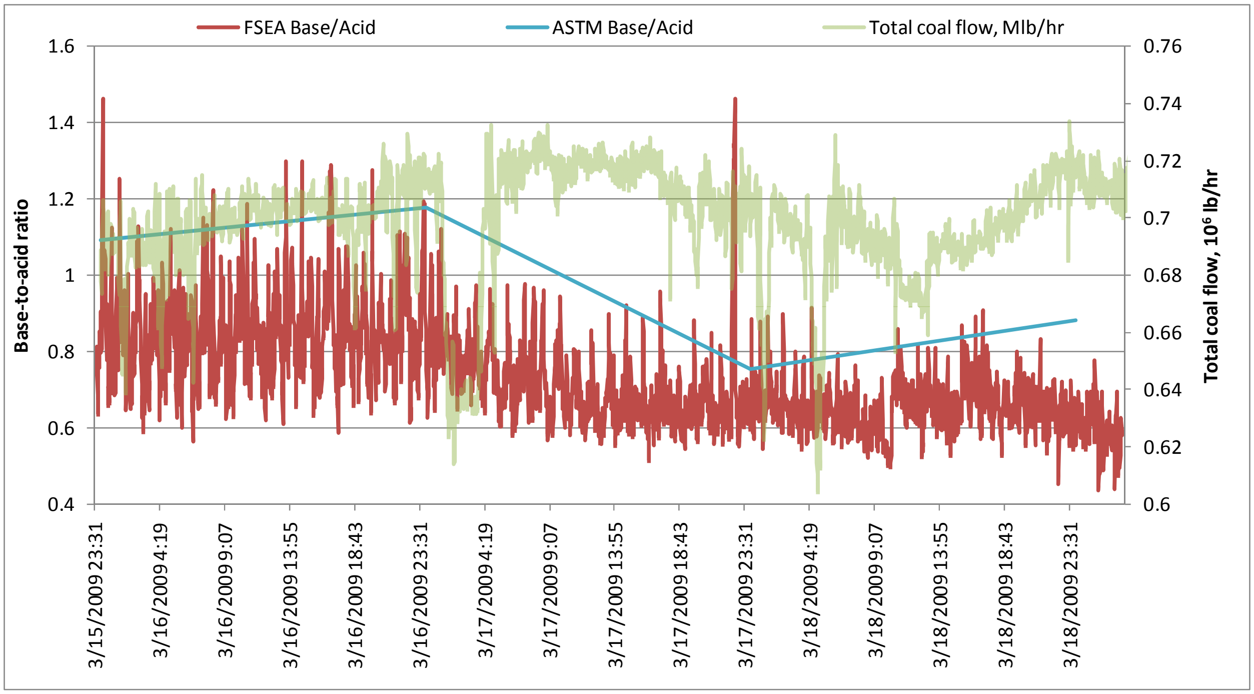

Figure 5. Coal belt flow and base-to-acid ratio (determined with FSEA and by ASTM ash composition analyses performed on composite coal samples) during the testing. The FSEA data was corrected for a 23-hour lag time between filling the hoppers and estimated fuel fed to the cyclones.

Particulate Mass and Number Distribution

Mass Distribution as Function of Location

The total mass loadings obtained with the multicyclone and impactors are illustrated in **Figure 6**. The results show a high average loading of 4.96x10^6 micrograms per dry standard cubic meter (µg/dscm) at the ESP inlet, and average scrubber inlet and outlet loadings of 1.1x10^4 µg/dscm and 1.08x10^4 µg/dscm, respectively. Significant removal of particulate occurred across the ESP, with removal efficiency of 99.76%. These results show that very little removal of particulate material has occurred across the wet scrubber system. This is consistent with past work conducted by Markowski and others (1983) (a literature review is contained in **Appendix B** of this report). The results are also summarized in **Table 8**.

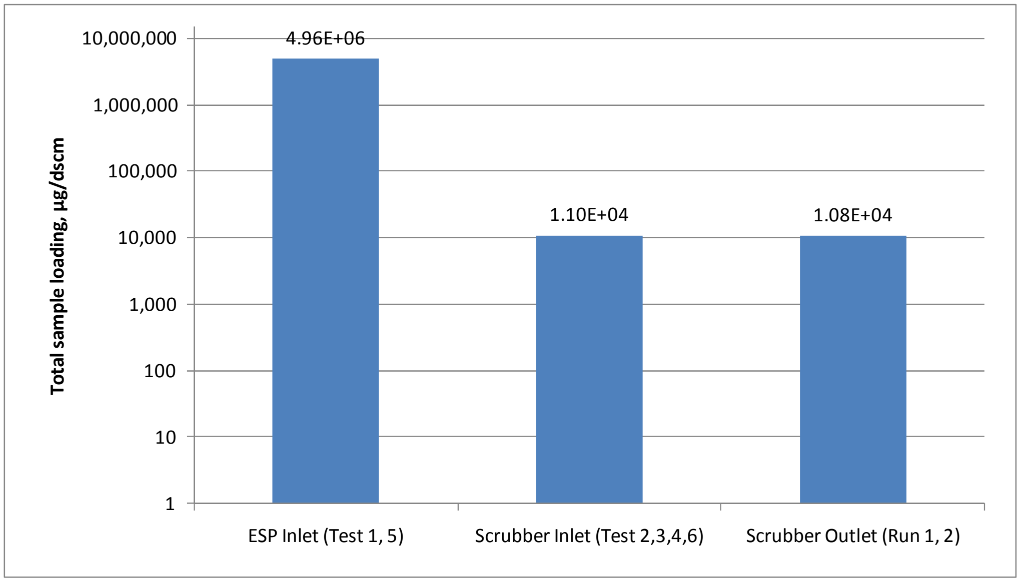

Figure 6. Total mass loadings at ESP inlet, wet scrubber inlet, and wet scrubber outlet.

Table 8. Total mass loadings for all testing conducted at ESP inlet, wet scrubber inlet, and wet scrubber outlet.

Location	Date	Test #	Sampler type	Sampler loading mg/dscm	µg/dscm	Total loading µg/dscm

Particulate Mass Loading as a Function of Size

Sampling at the ESP inlet was conducted using both the multicyclone and the impactor. The cyclones are designed to capture larger-size particles and the impactor collects small particles. **Figure 7** shows the mass size distributions for the cyclone and impactor. The size distribution of the particulate at the ESP inlet is multimodal. The larger particles are typically derived from mineral grains in the coal such as quartz, clays, and pyrite minerals. The intermediate-sized particles are typically derived from small minerals and organically associated elements. Particles less than a micron in diameter and finer are condensed vapor phase species.

The sample collected on 3/17/09 show a multimodal size distribution, with a mode occurring at one to three microns, and another mode at 0.1 μm. The sample collected on 3/19/09 also has a multimodal distribution, with a shift in the finer mode from 0.1 μm to about 0.5 μm. This shift may be due to the change in fuel composition (the coal sample collected on 3/17/09 had a higher base-to-acid ratio as compared to the coal collected on 3/19/09).

The mass size distribution of the particulate collected upstream of the scrubber is illustrated in **Figure 8**. Sampling was conducted at this location on all four days of the period. The results show a bimodal distribution of particles with a mode between one to two microns and another mode between seven and eleven microns. A general trend of decreasing abundance of the modes during the testing is observed. The change in abundance is likely due to changes in coal ash composition. Coals sampled on 3/16 and 3/17 had higher base-to-acid ratios; coals on 3/18 and 3/19 had lower ratios.

The mass size distribution of the scrubber outlet particulate is illustrated in **Figure 9**. The size distribution shows a main mode at about 0.8 μm and possibly a minor larger mode of 2 μm. The particle size distribution is shifted to finer particles downstream of the scrubber and the smaller particle size mode appears to dominate the size distribution. The samples were collected on 3/18 and 3/19, when the coals fired had lower base-to-acid ratios.

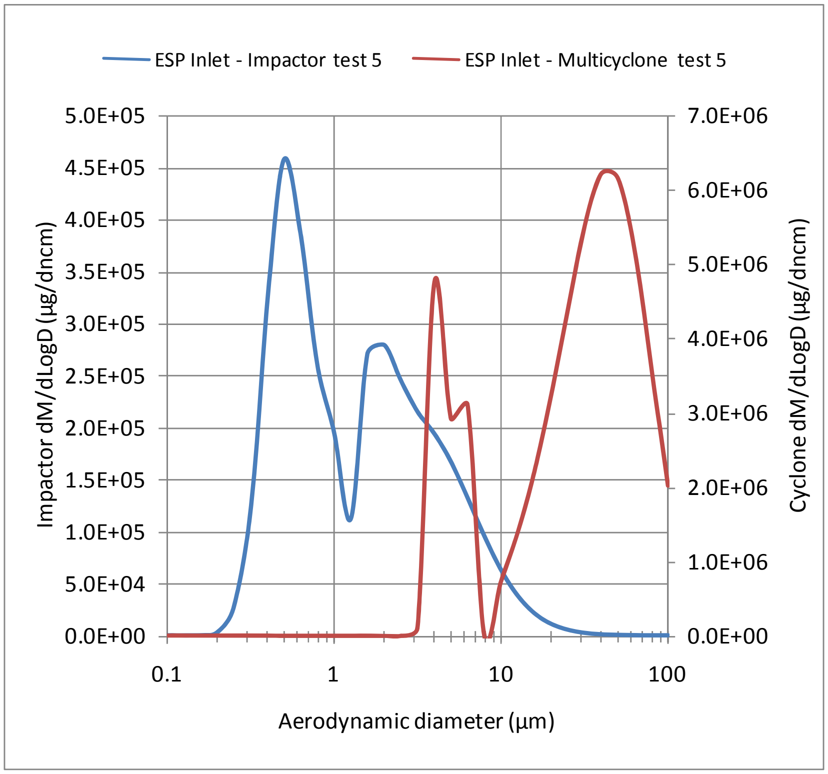

Figure 7b. Multicyclone and impactor data collected at ESP inlet on 3/19/09.

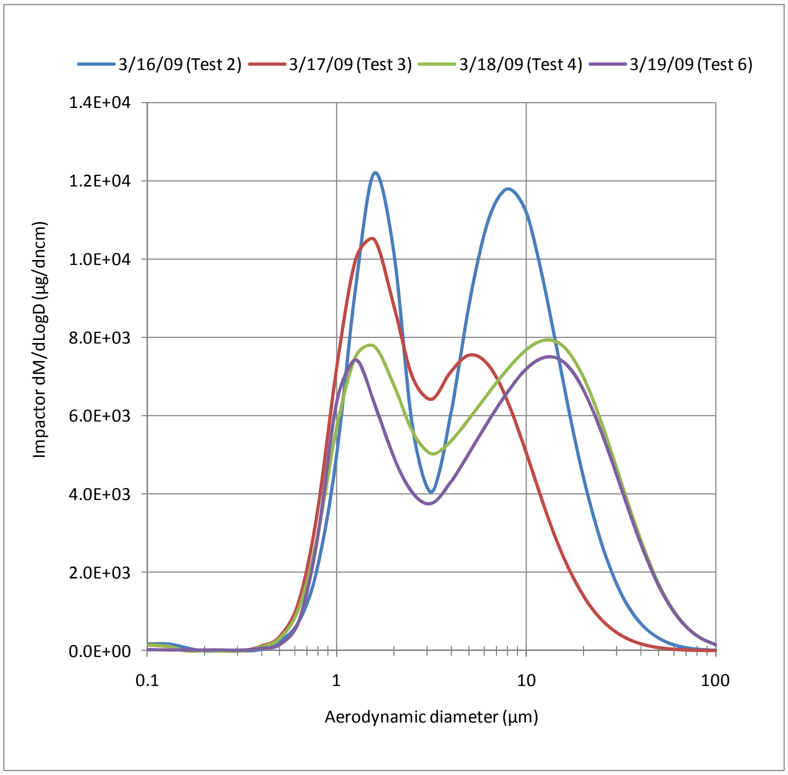

Figure 8. Mass versus size distribution of ash collected downstream of the ESP at the scrubber inlet.

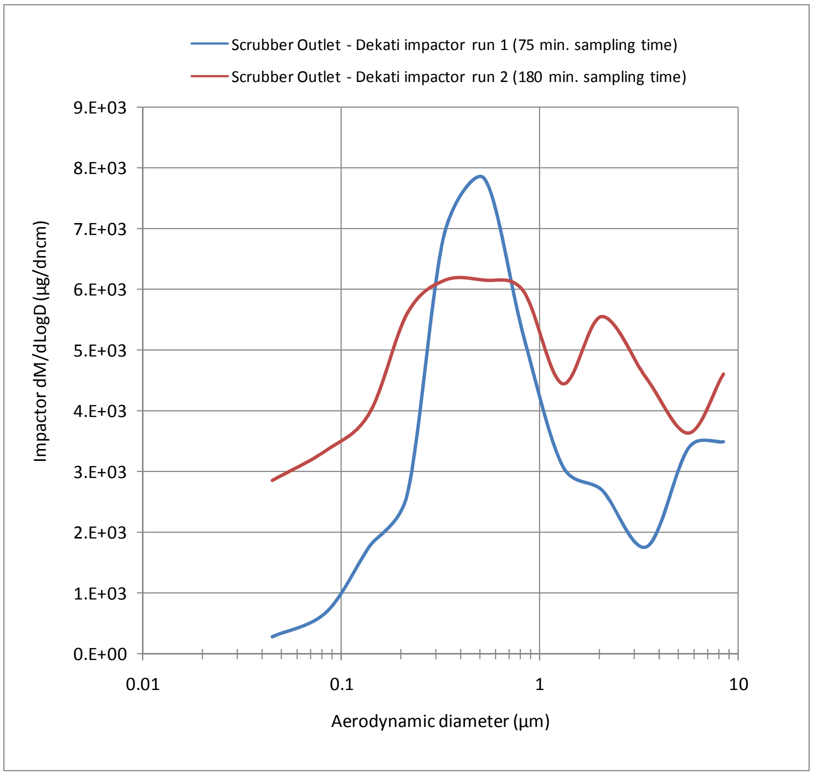

Figure 9. Mass distribution of particulate collected downstream of scrubber.

Particle Number Size Distribution

The number distributions for the particles are shown in **Figures 10** through **12** for the ESP inlet, scrubber inlet, and scrubber outlet. This information is shown as the number of particles per dry normal cubic centimeters (*not* cubic meters ash summarized above). This is the convention used by researchers.

The number of particle increases significantly with decreasing particles size. **Figure 10** shows the number of particles for the scrubber inlet. The ESP inlet sample had the highest number of particles in the smallest size fraction. The number of particles in the smallest size fraction at the scrubber inlet and outlet are similar – the slight increase in number at the scrubber outlet is likely to differences in sampling methods.

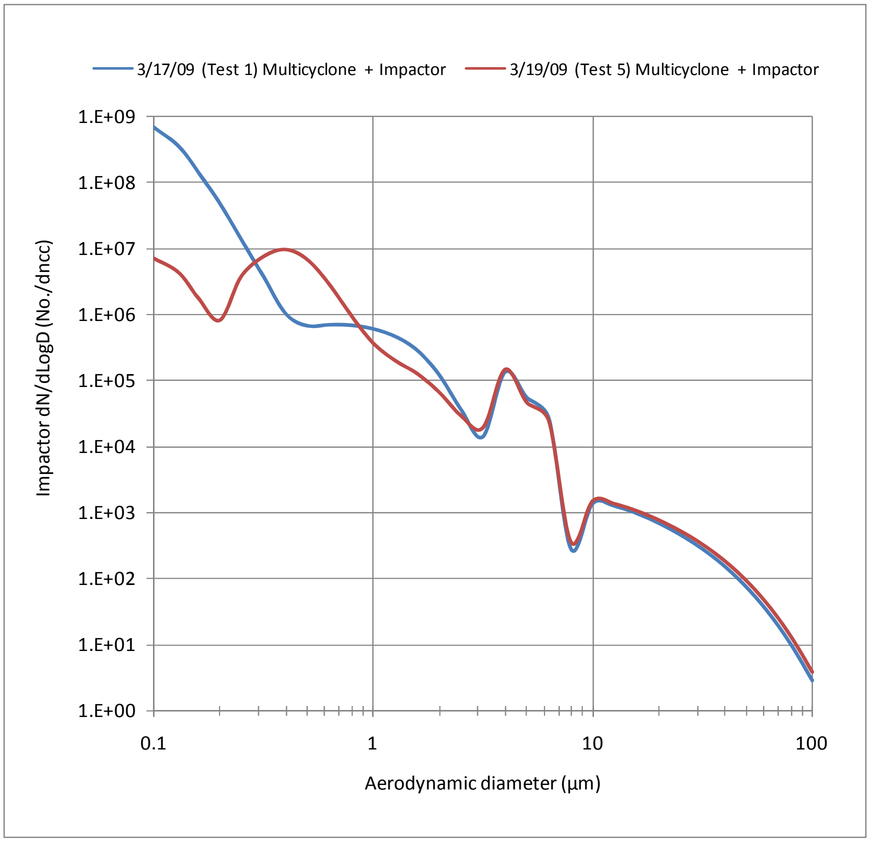

Figure 10. Number of particles as a function of size at the ESP Inlet.

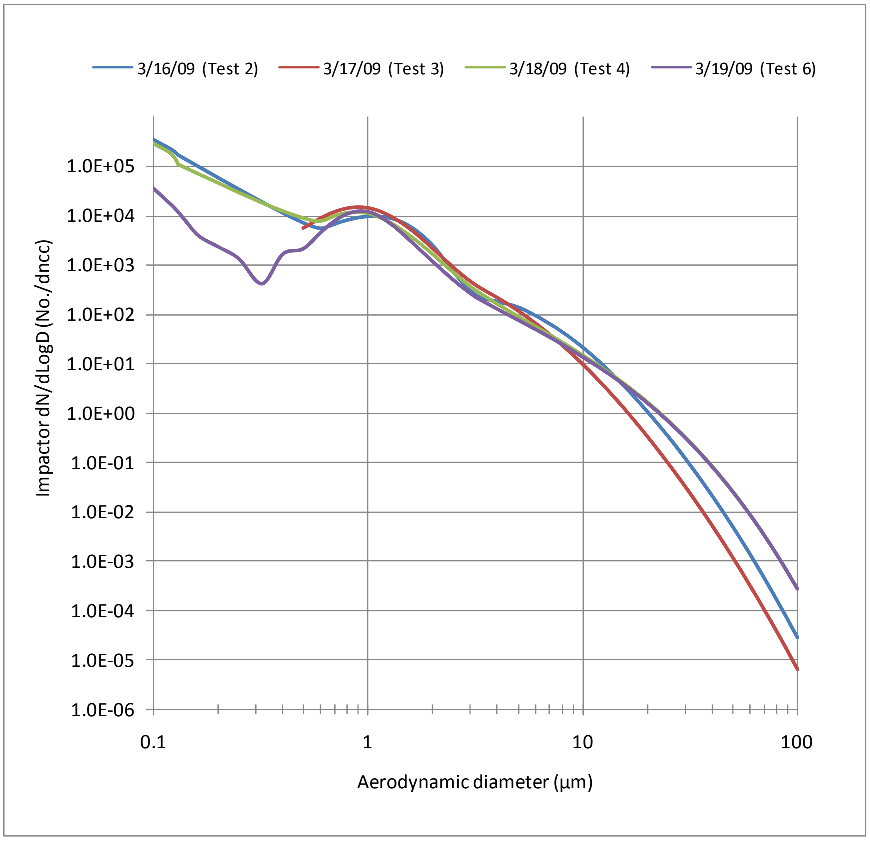

Figure 11. Number of particles as a function of size at the scrubber inlet.

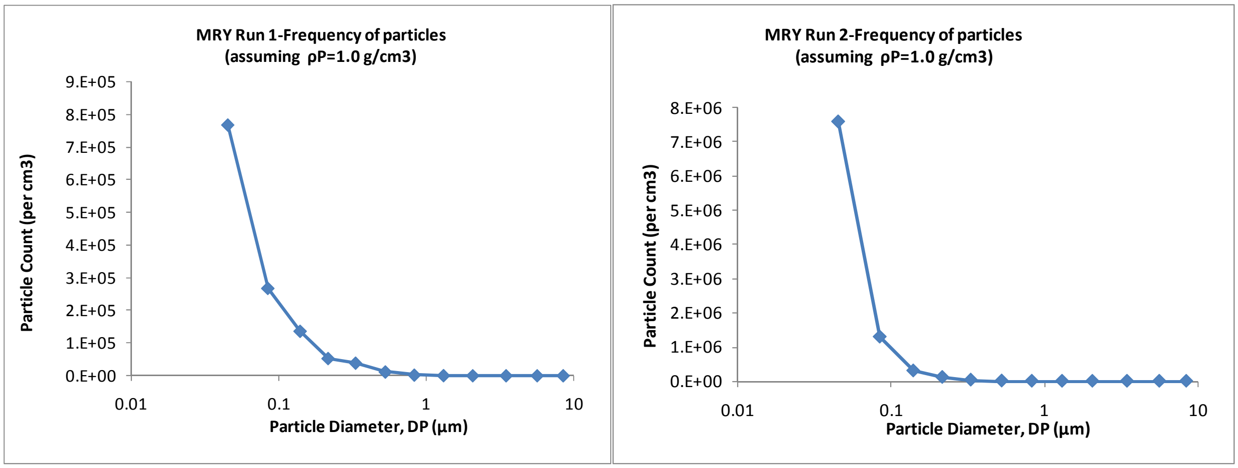

Figure 12. Number of particles as a function of size at the scrubber outlet.

Scanning Mobility Particle Scanning (SMPS)

Number-based concentration data obtained by the SMPS system at the scrubber outlet is shown in **Figures 13** and **14**. The data shown are for the on one good data set obtained during the sampling trip. A summary of the conditions at the sampling site that limited the ability of the SMPS to gain reliable data is listed in the Appendix.

The SMPS reports size data on a nanometer (nm) scale, not a micrometer (µm) scale. There are 1,000 nm in one micron. The data shown was obtained from a 10-sample test run, each 60 seconds apart, and includes two scans per sample: 60 seconds for the up scan and 30 seconds for the down scan. The scan window of the instrument covers a particle range of 16.5–605 nm (0.0165–0.605 µm).

Plots of the concentration versus particle diameter are given in **Figure 13** for number basis and in **Figure 14** for the mass basis. The number of particles observed using the SMPS is larger than that observed for the impactors but it is generally consistent the impactor data.

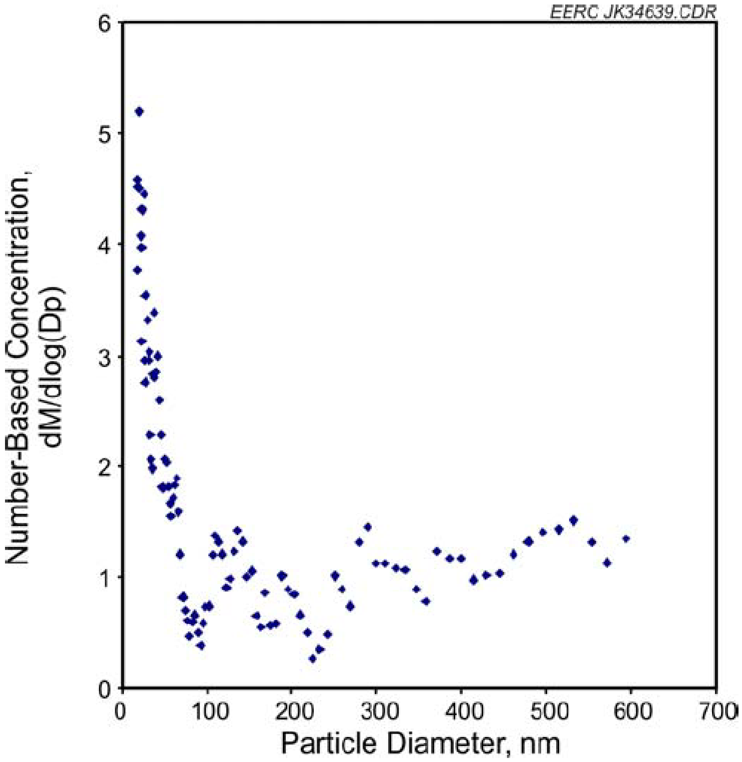

Figure 13. Plot of number-based particle concentration as a function of particle diameter (nanometers).

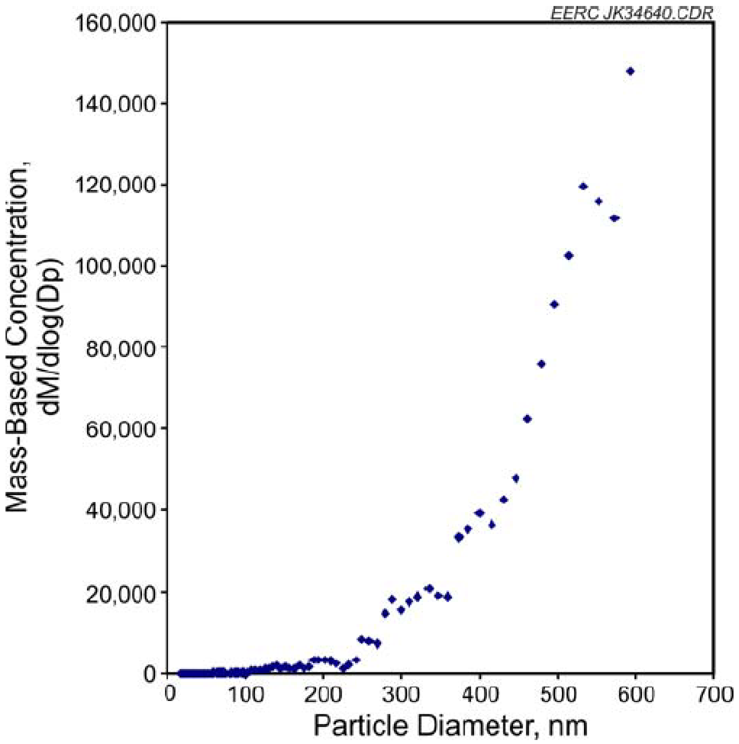

Figure 14. Plot of mass-based particle concentration as a function of particle diameter (nanometers).

Bulk Composition of Ash Materials

The composition of the size fractions of ash materials collected using the multicyclone are summarized for the element of interest specifically the Na, K, Ca, and S. These elements produce very small particles upon combustion. Data is available in the appendix that includes the major elements determined. The trends for the ESP inlet are shown in **Figure 15** for sodium, potassium, calcium and sulfur, and in **Figure 16** for silicon, aluminum, magnesium and iron. The results show concentrating of the elements in the particles that are less than 10 μm in diameter.

Figure 17 shows the trend for the ESP inlet cyclone samples (cyclones 1, 3 and 4) for sodium, potassium, calcium and sulfur and **Figure 18** shows the trends for silicon, aluminum, magnesium and iron for the ESP inlet cyclone samples.

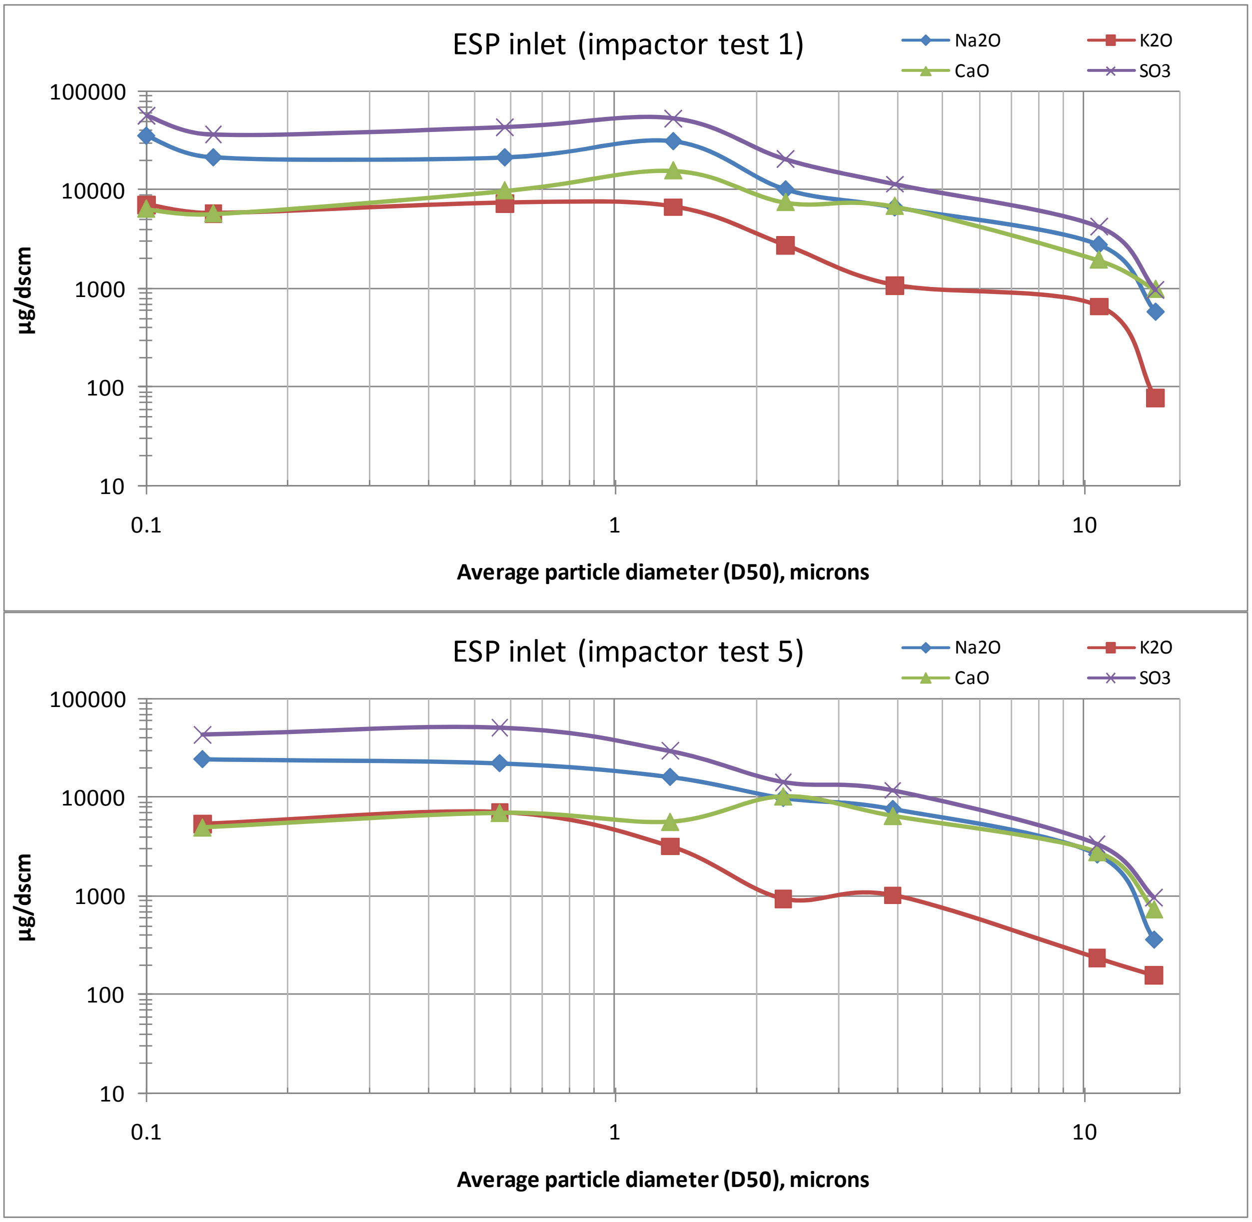

Figure 15. Sodium, potassium, calcium and sulfur concentrations as a function of average particle diameter for ESP inlet (impactor) samples.

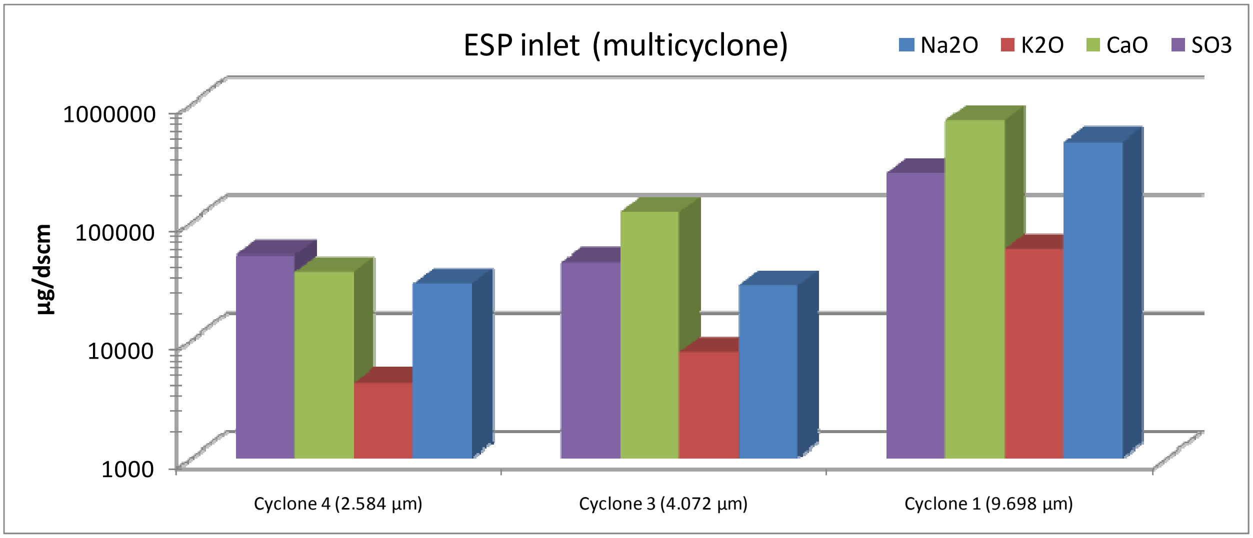

Figure 17. Sodium, potassium, calcium and sulfur concentrations for ESP inlet cyclone samples.

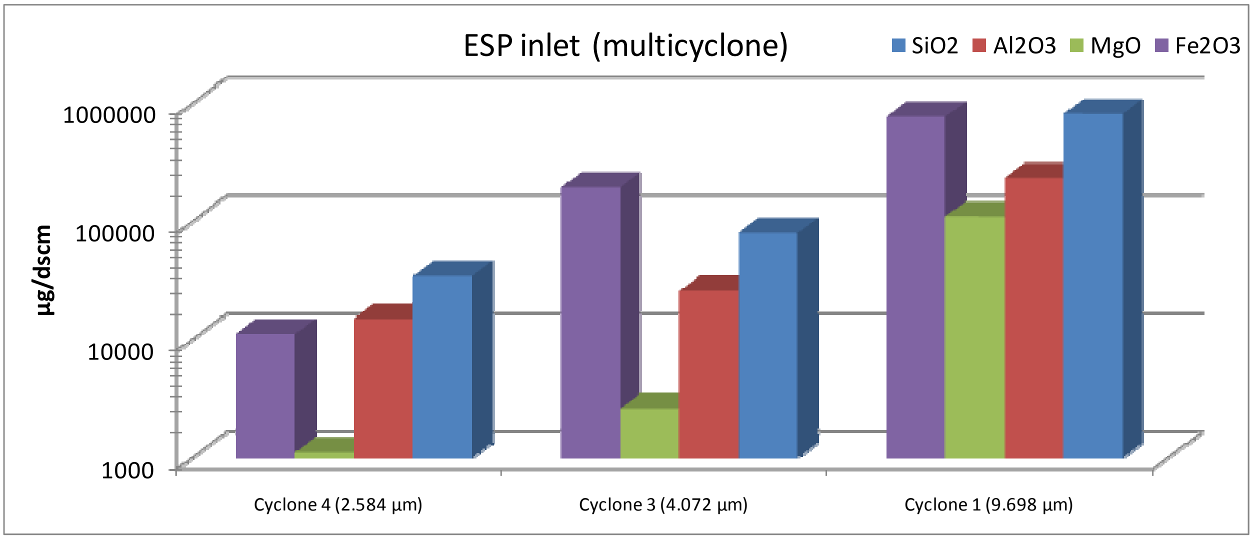

Figure 18. Silicon, aluminum, magnesium and iron concentrations for ESP inlet cyclone samples.

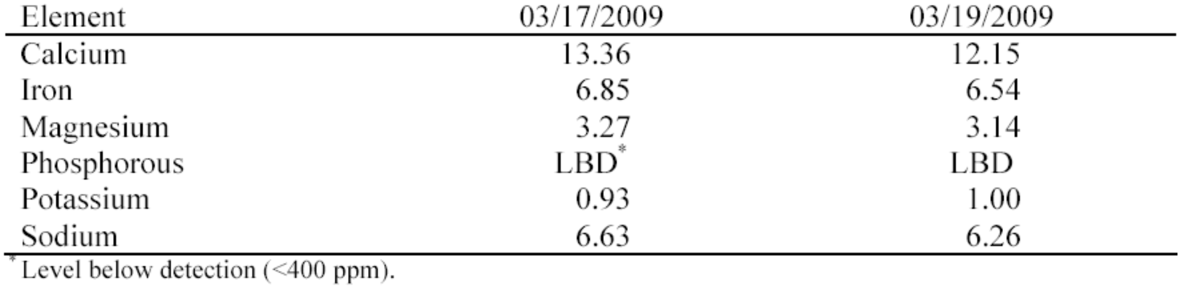
Analysis using digestion and inductively coupled plasma–mass spectrometry was performed to determine the concentrations of selected major elements (Ca, Fe, Mg, P, K, and Na) in the ash collected in the multicyclone stages. Table 9 lists the composition of selected elements based on the total sample collected in the multicyclone. Table 10 displays the fraction of each element, based on the total percent found in Table 9, by each cyclone stage. The largest concentrations of the selected elements were found in the first cyclone stage. The nozzle sample is material collected within the nozzle before the first multicyclone stage. This material is not size-fractionated.

The concentrations of the cyclone ash analyzed with ICP-MS cannot be compared well with the ash analyzed using SEM, as the ICP-MS samples were not analyzed for all major elements (including silicon, aluminum and sulfur).

Table 9. Percentage of each element in the total multicyclone sample (EERC).



Element	03/17/2009	03/19/2009
Calcium	13.36	12.15
Iron	6.85	6.54
Magnesium	3.27	3.14
Phosphorous	LBD*	LBD
Potassium	0.93	1.00
Sodium	6.63	6.26

* Level below detection (<400 ppm).

Table 10. Fractional percentage of each element by stage (EERC).

	03/17/2009				03/19/2009			
Element	Nozzle	Stage 1	Stage 3	Stage 4	Nozzle	Stage 1	Stage 3	Stage 4
Calcium	3.96	81.23	11.63	3.18	4.99	81.98	9.77	3.26
Iron	4.21	81.77	10.16	3.86	5.25	81.06	8.90	4.79
Magnesium	4.10	81.45	11.71	2.75	5.25	81.81	9.91	3.03
Phosphorous	LBD	LBD	LBD	LBD	LBD	LBD	LBD	LBD
Potassium	3.91	77.32	12.77	5.99	5.08	80.67	10.18	4.07
Sodium	4.21	77.80	12.82	5.17	5.67	80.59	9.88	3.85

The distribution of sodium, potassium, calcium and sulfur is illustrated in **Figure 19** and the distribution of silicon, aluminum, magnesium and iron is shown in **Figure 20**. The results show higher levels of sodium, potassium and sulfur at the one-micron level. The ESP was effective in removing larger-sized particles as well as some of the 0.1-µm particles. However, in the intermediate one-micron particle range the ESP is not as effective in removing the particles. This is a characteristic of all ESPs.

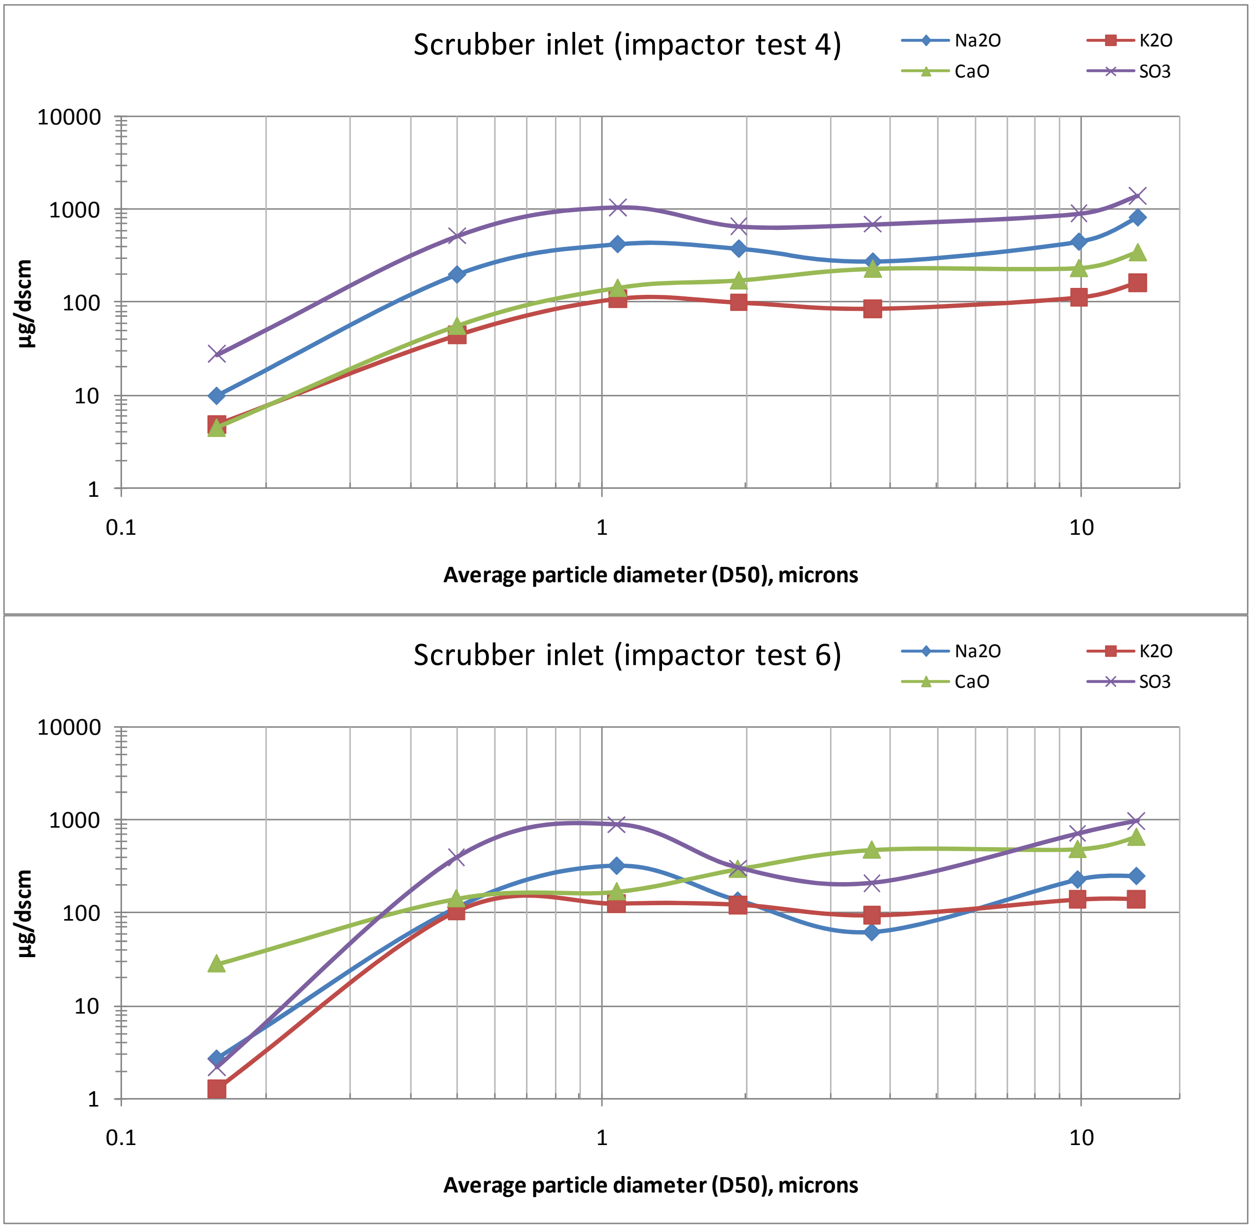


Figure 19. Sodium, potassium, calcium and sulfur concentrations as a function of average particle diameter in scrubber inlet samples.

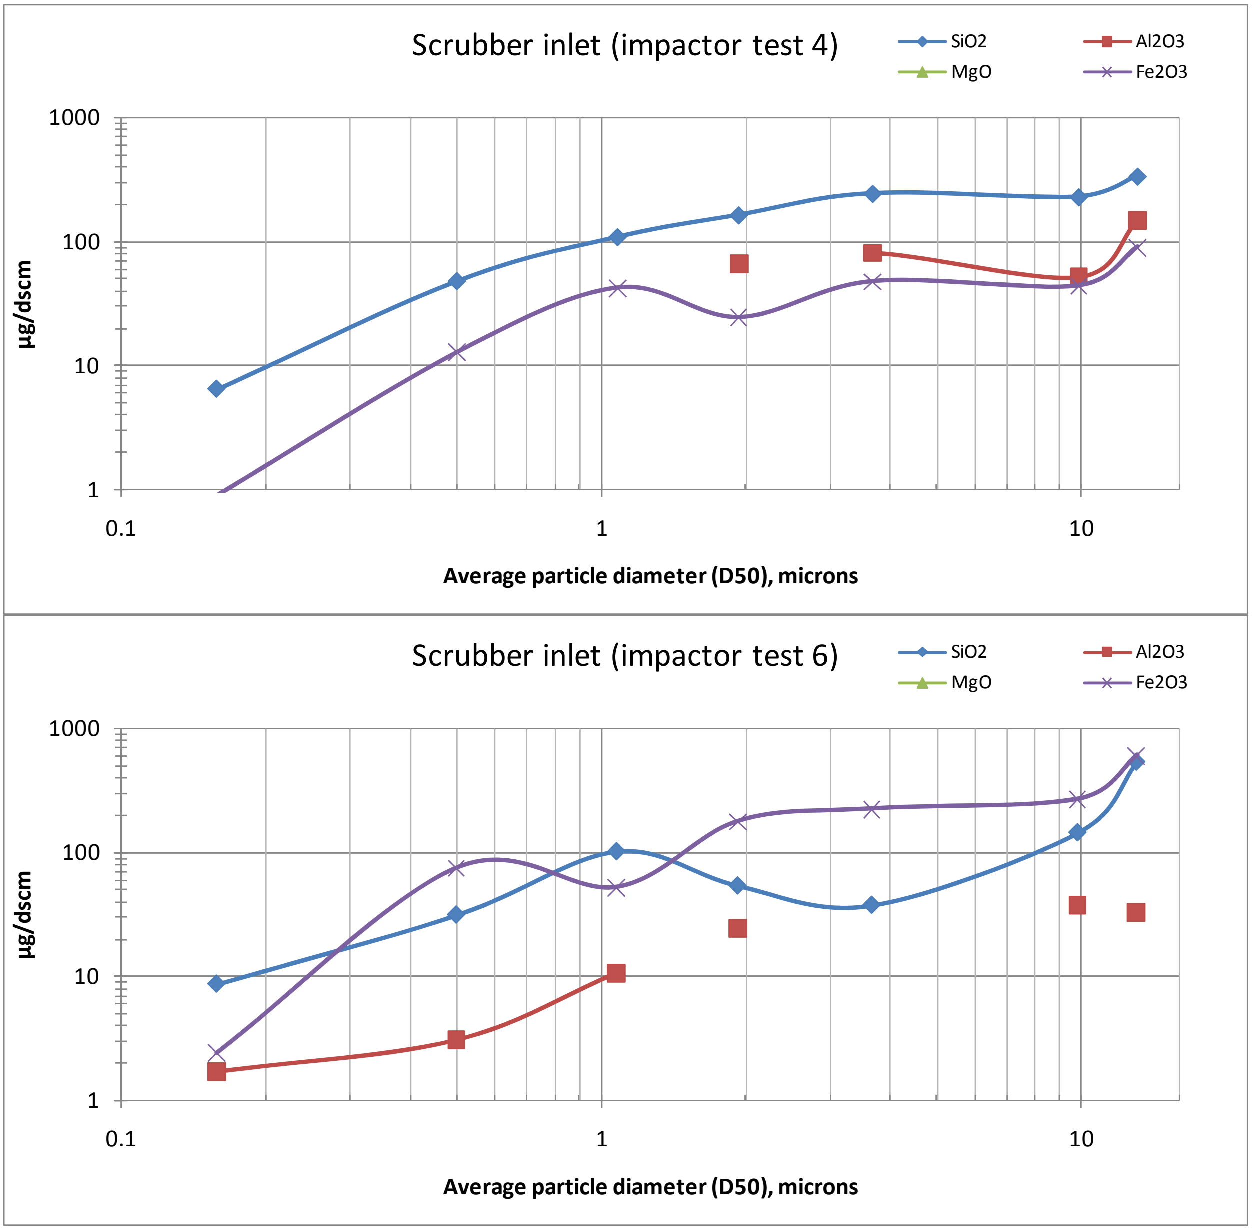

Figure 20. Silicon, aluminum, magnesium and iron concentrations as a function of average particle diameter in scrubber inlet samples.

The composition size distribution determined for sodium, potassium, calcium and sulfur downstream of the scrubber is illustrated in Figure 21. The results show a significant level of sodium and sulfur in the less than 1 µm size fraction. The DLPI sampling system provides very accurate sizing data in the submicron size range. The results show a maximum for sodium and sulfur at about 0.3 µm.

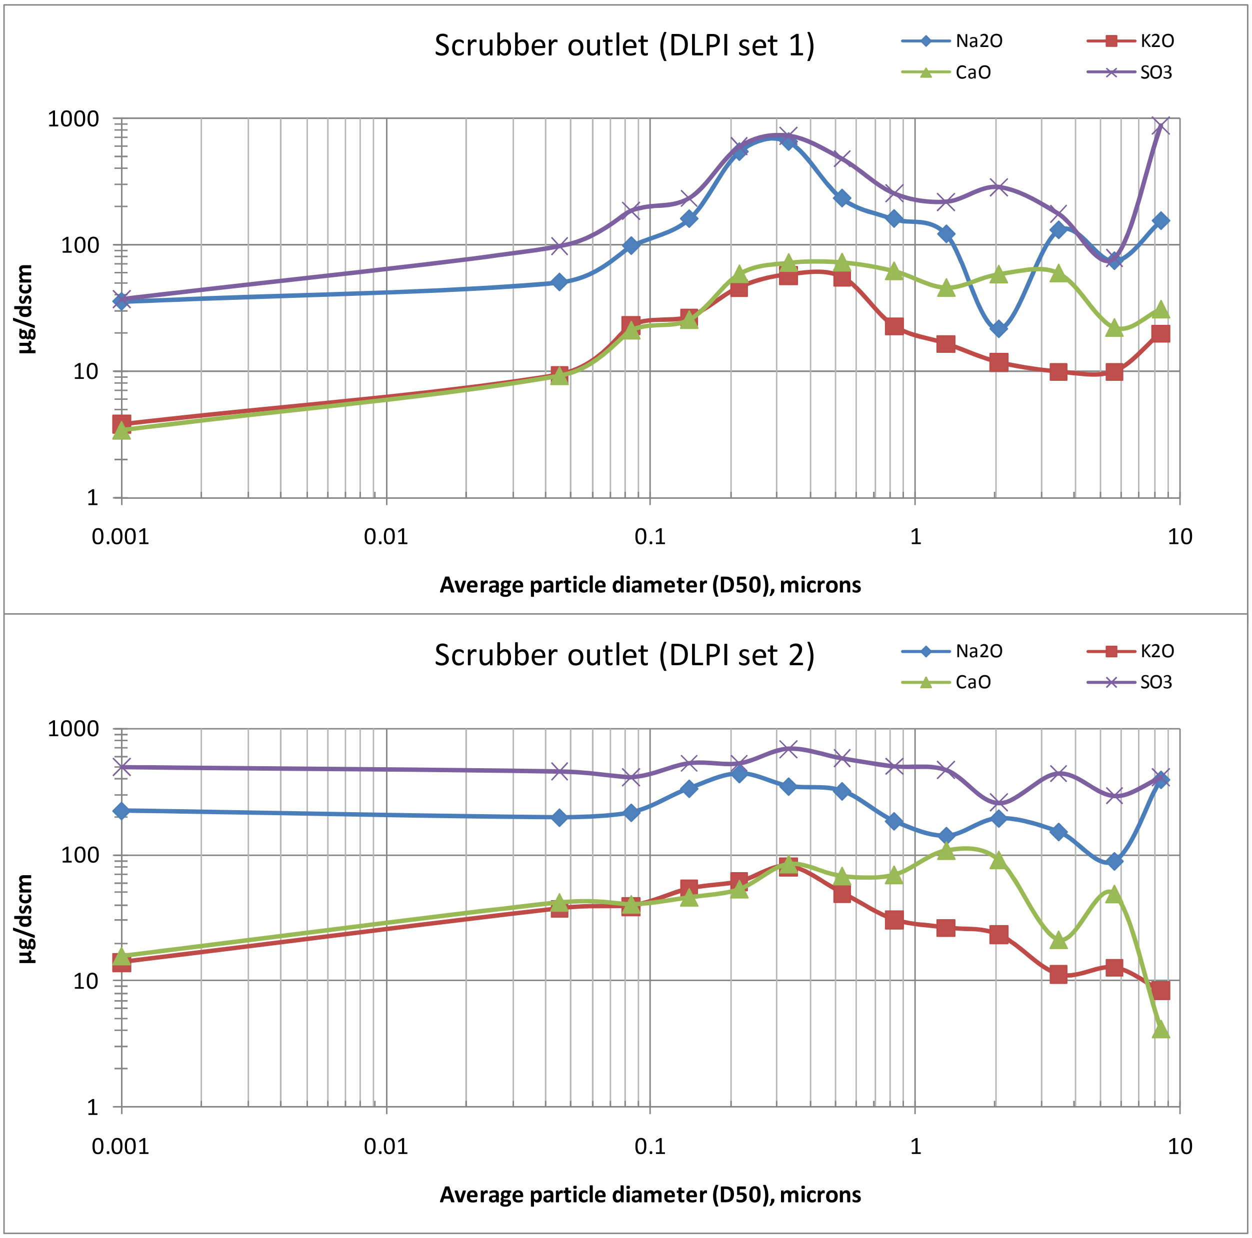

Figure 21. Sodium, potassium, calcium and sulfur concentrations as a function of average particle diameter in scrubber outlet samples.

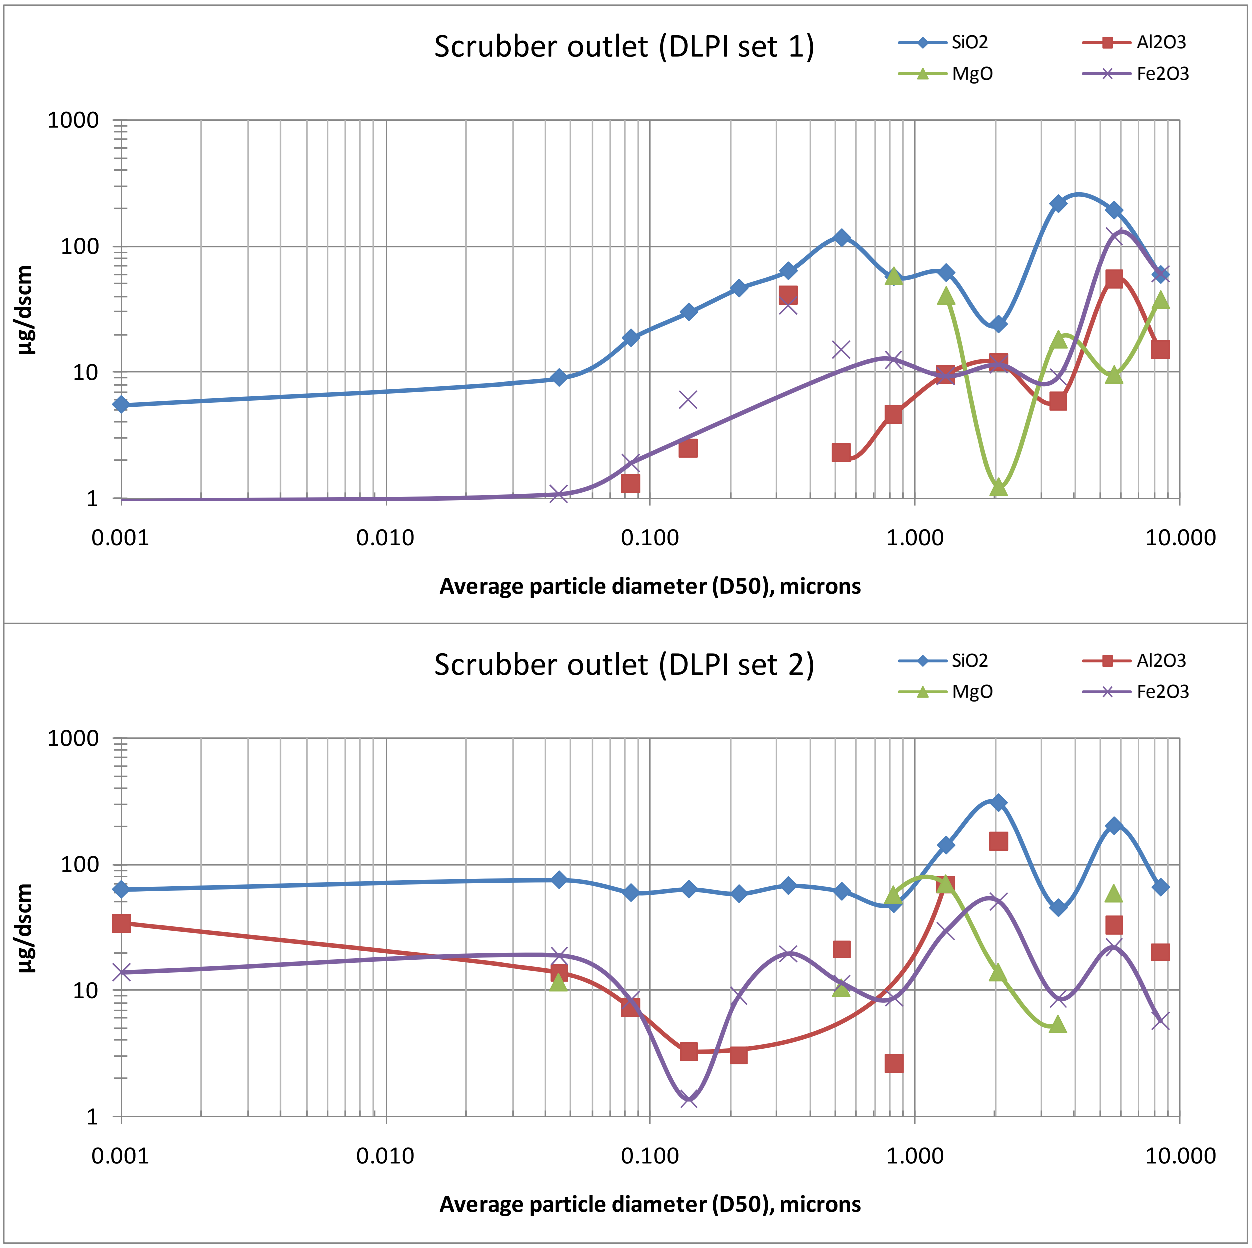

Figure 22. Silicon, aluminum, magnesium and iron concentrations as a function of average particle diameter in scrubber outlet samples.

Comparison of the mass of the particles in terms of composition is shown in **Figure 23**. The results show that sodium and potassium are reduced across the ESP. However, no reduction of sodium and potassium was observed across the scrubber. This is consistent with other scrubbers operating globally.

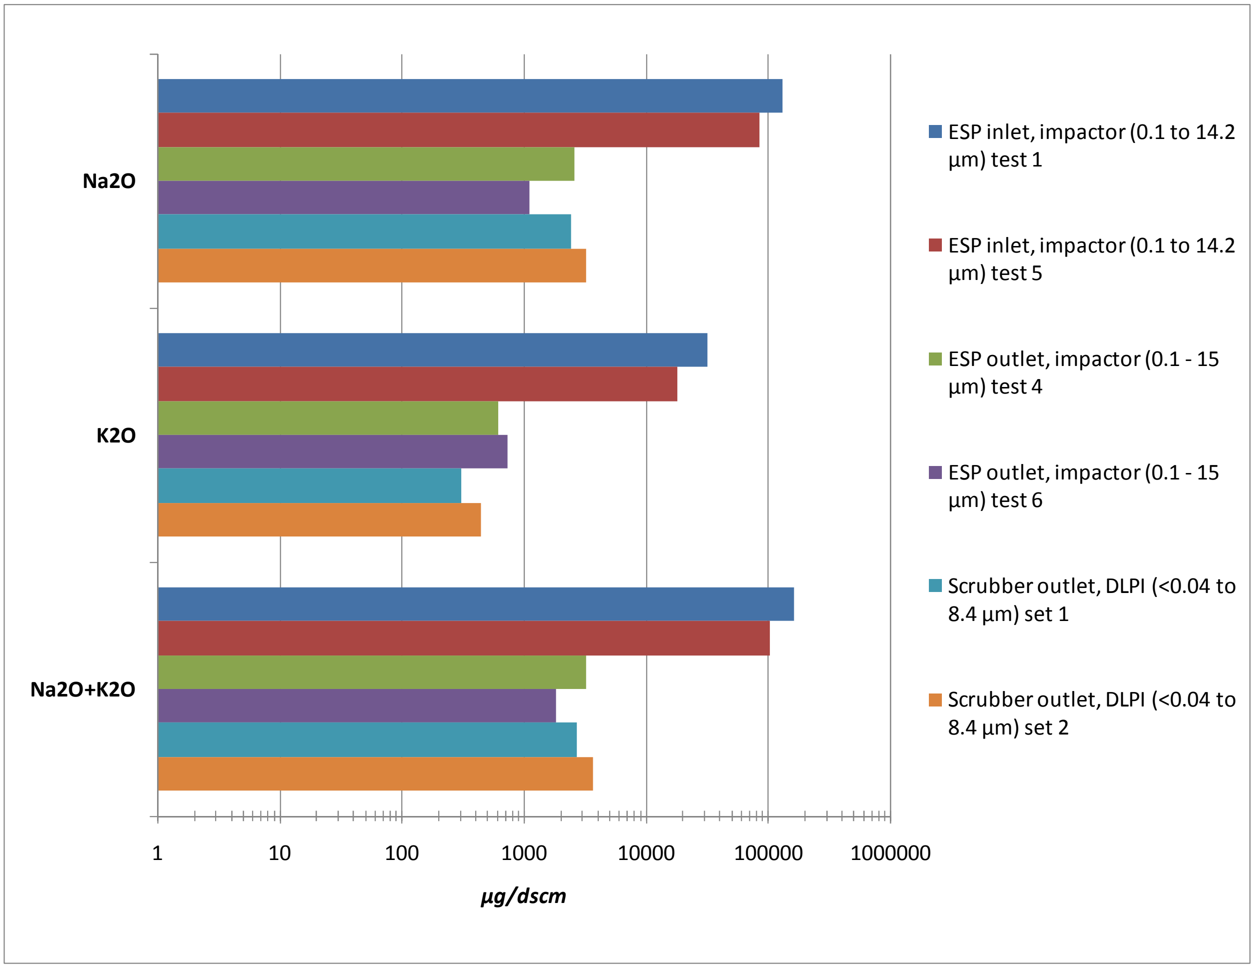

Figure 23. Mass of sodium and potassium oxide in the flue gas upstream and downstream of air pollution control devices at MRY.

SUMMARY AND CONCLUSIONS

Particulate sampling was conducted at Minnkota Power Cooperative's Milton R. Young plant to determine the particulate size and composition distribution of samples collected upstream of the ESP, upstream of the wet scrubber, and downstream of the wet scrubber. Emphasis was placed on determining the fate of sodium, potassium, and calcium since these elements can cause significant plugging and deposition problem.

During the testing, operating conditions of the plant were constant and there was no gas bypass. The coal fired during the testing remained relatively consistent. The as-received ash content ranged from 7.73 to 7.89%. Sodium oxide content of the ash ranged from 7.22 to 7.57% and the base-to-acid ratio decreased the last two days of testing (a result of a decrease in CaO content and an increase in SiO_2 and Al_2O_3 levels). Sampling upstream of the ESP and scrubber were conducted using a combination multicylones and impactors. The cyclones collected sized fractions of larger particles (greater than one to five microns) and the impactor collected the sub-micron particulate. Sampling downstream of the scrubber was conducted with a single cyclone followed by a 13-stage advanced impactor. In addition, the submicron particle number concentration was measured using a scanning mobility particle sizer (SMPS).

The results of the particulate mass information indicated a high loading at the ESP inlet of 4.96×10^6 µg/dscm, a scrubber inlet loading of 1.1×10^4 µg/dscm, and a scrubber outlet loading of 1.08×10^4 µg/dscm. These results show very little overall removal of the submicron particulate across the wet scrubber system. A significant fraction of the particulate was removed by the ESP, with a removal efficiency of 99.76%.

The size distribution of the particulate collected upstream of the ESP and upstream of the scrubber was multi-modal as summarized below:

- Upstream of the ESP there were at least three modes – a larger mode at 40 to 50 µm, a second mode at just under 10 µm, and third mode at about 1 µm. The larger particles are typically derived from mineral grains in the coal such as quartz, clays, and pyrite. The intermediate-sized particles are typically derived from small minerals and organically associated elements. The smaller mode (about one-micron and smaller) contains fine particles and condensed vapor phase species.
- Upstream of the scrubber there were two distinct modes – a larger mode between 8 to 10 µm and another mode centered at about 1 to 2 µm in diameter. The smaller mode is typically condensed vapor phase and small particles.
- Downstream of the scrubber, the primary mode centered at about 0.5 to 0.7 µm, and another possible mode occurred at 3 µm and larger.
- Particle number distributions were as follows:
    - Inlet to the ESP – between 1×10^7 to 10^8 particles per dry normal cubic centimeter (dncc);
    - Inlet to the scrubber is 10^5 particles/dncc;
    - Outlet of the scrubber 7×10^5 particles/dncc.
- Particle number distributions into the nanometer scale (1 µm = 1000 nm) was found to be as high as 10^5 particles/dncc.

Particle composition distributions of the particulate were determined for each of the major elements. The results were reported as µg/dscm of the element as illustrated in the Appendix and in the figures in the text.

- Upstream of the ESP the composition trends for sodium, potassium, calcium and sulfur showed greater concentrations of these elements in the particles that are smaller than 10 µm, with a significant increase in concentration in the flue gas at a particle size of less than 2 µm. There is another increase at 0.1 µm.
- Upstream of the scrubber the compositional trends for sodium, potassium, calcium and sulfur show higher levels at the 1 µm level. The ESP was effective in removing larger-sized particles, as well as some of the 0.1 µm particles. However, in the intermediate 1 µm particles, the ESP is not as effective in removing the particles.
- Downstream of the scrubber the composition size distribution determined for sodium, potassium, calcium and sulfur showed significant levels of sodium and sulfur in size fraction finer than 1 µm. The DLPI sampling system provides very accurate sizing data in the submicron size range. Other elements such as aluminum, silicon and iron show a significant depletion below 1 µm.

Comparison of the characteristics of the particles in terms of mass and composition indicate that, at the time of the testing, the total average mass of the particulate was about 10,800 µg/dscm. The particulate consisted mainly of sodium, potassium, and sulfur. The total quantity of sodium and potassium exiting was between 2000 to 3000 µg/dscm.

APPENDIX B - SMPS FIELD CONDITIONS AND CHALLENGES

Temperature

The temperature in the field during this test was approximately 24°F. This made it very difficult for the equipment to start and warm up to normal operation conditions, especially the CPC. With the help of a fish tent, carpets, and small blow heaters, the CPC was brought to normal operating temperature. Because of the cold conditions, there was a significant condensation issue in the lines that fed the SMPS system. Although this problem was reasonably resolved for all lines from the probe end to the EC by applying heat/thermal tapes, the lines connecting the EC and CPC also had a buildup of condensed fluid to the extent that they had to be drained at one point to help stabilize the flow via the CPC pump.

Wind

Another challenge faced in the field was the high winds of more than 20 mph. With the scrubber outlet location being about 105 feet above the ground, such windy conditions constantly shook the grid and the equipment; thereby introducing turbulence to the flow through the CPC pump.

Pore Flue Gas Pressure

A more serious problem was the lack of adequate positive pressure from the sampling port to supply enough flue gas through lines into the SMPS system. This resulted in very low counts observed in many data sets. Although the sampling port at the scrubber outlet is at positive pressure, it probably was not high enough to feed enough flue gas through the small nozzle of the sampling probe to the SMPS system.

Milton R. Young Unit 2

MRY Unit 2 is a Babcock & Wilcox (B&W) Carolina-type radiant boiler designed to burn high-moisture, high-slagging/fouling North Dakota lignite. Nominally rated at 3,050,000 lb/hr, this unit is a cyclone-fired, balanced-draft, pump-assisted circulation boiler. The unit began commercial operation in May 1977 and is base-loaded at 470 MW gross. The unit is equipped with a cold-side ESP for particulate control and a wet FGD unit for SO_2 control. The cold-side ESP has a specific collection area (SCA) of 375 ft^2/1000 acfm. The wet FGD for SO_2 control utilizes alkaline ash and lime. The MRY Station fires North Dakota lignite coal from the Kinneman Creek and Hagel Seams at the Center Mine.

Form of Sodium in Center Lignite

Sodium is associated with the organic matrix in Center lignite. That means the sodium is atomically dispersed in the organic matrix. The sodium is associated with a carboxylic acid groups (ion exchange sites). The carboxylic acid groups act as bonding sites for various elements such as Ba, Ca, Mg, and Sr along with minor amounts of K. Figure C-1 illustrates the bonding of sodium to the organic fraction of the coal and the association of other coal impurities.

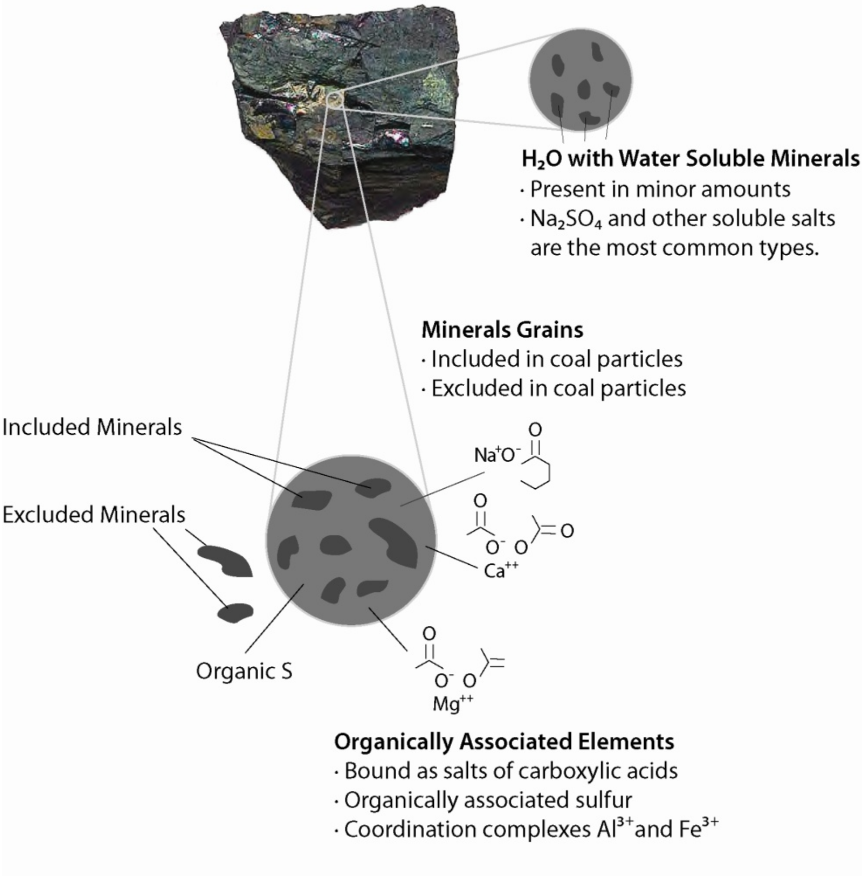

Figure C-1. Form of sodium in coal (Benson and Laumb, 2008).

Vaporization of sodium in PC and cyclone-fired systems

Sodium is a volatile element and will be transformed into a gas upon combustion. The vaporization of sodium during the combustion of lignite is a very well known fact that has been examined by numerous investigators; include work conducted by MIT, CalTech, Sandia National Laboratory, National Energy Technology Laboratory, University of Utah, and others. For example, research conducted by Senior and others (2000) reported that relative to other coals, North Dakota lignite produced more vaporized ash. The actual amount vaporized for ND lignite is double the level vaporized as compared to subbituminous and lignite coals from Montana as illustrated in Figure C-2. Work conducted at the MRY plant related to the vaporization of sodium from a cyclone fired systems is illustrated in Figure C-3. The results show over two thirds of the sodium is not retained in the slag and is vaporized.

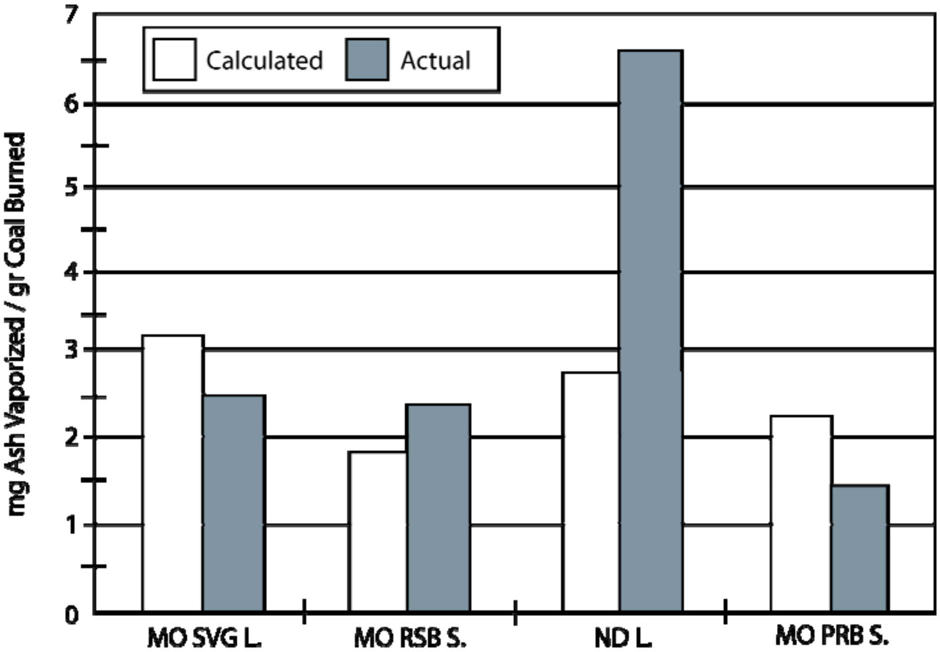

Figure C-2. Ash vaporized during combustion of lignite and subbituminous coals (Senior and others, 2000).

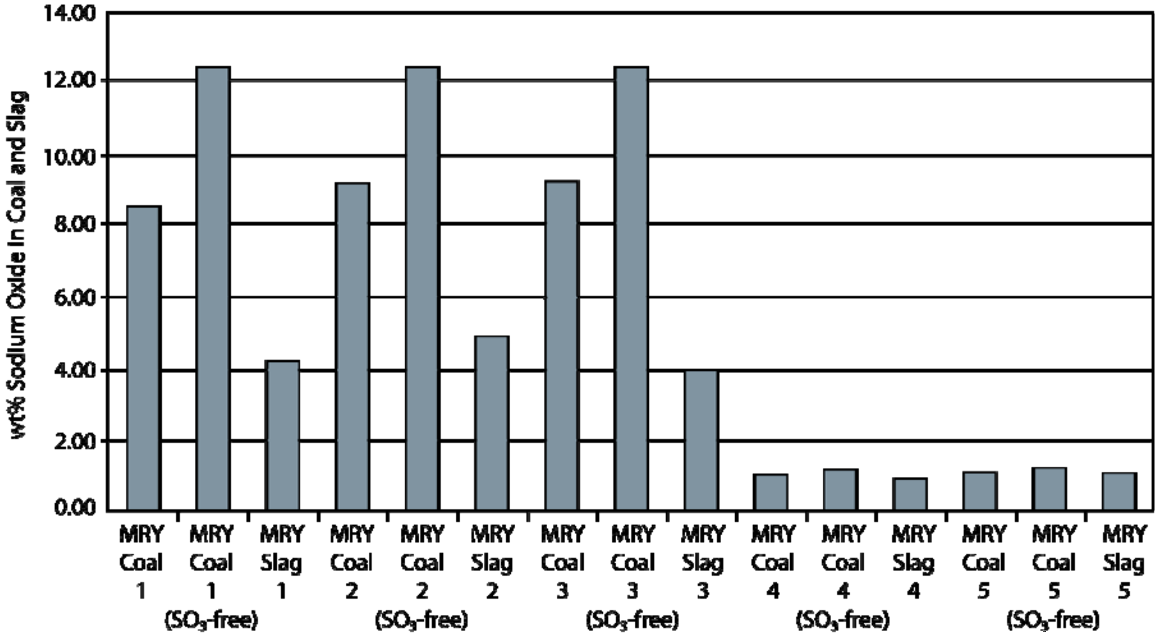

Figure C-3. Comparison of sodium levels in Center lignite coal and slag samples.

Condensation of vaporized species to form aerosols

EPA has evaluated the literature on particle formation during combustion and from other sources and incorporated it into an educational module that can be found on the following website (http://www.epa.gov/apti/bces/module3/formation/formate.htm). The classification of particle types shown by EPA is illustrated in Figure C-4. The EPA classification is consistent with the review conducted by Lighty and others (2000). Vaporized species can condense heterogeneously on surface of other entrained coarse ash particle and can condense homogeneously to form the fine and ultrafine particles. The distribution of particles depicted in Figure C-4 is shown on a frequency percent of particles by mass basis. The particle number versus size is also important and a comparison of the number of particles and particle size is summarized in Table C-1. The number of aerosol particles is significant. These particles have high surface areas and are very reactive.

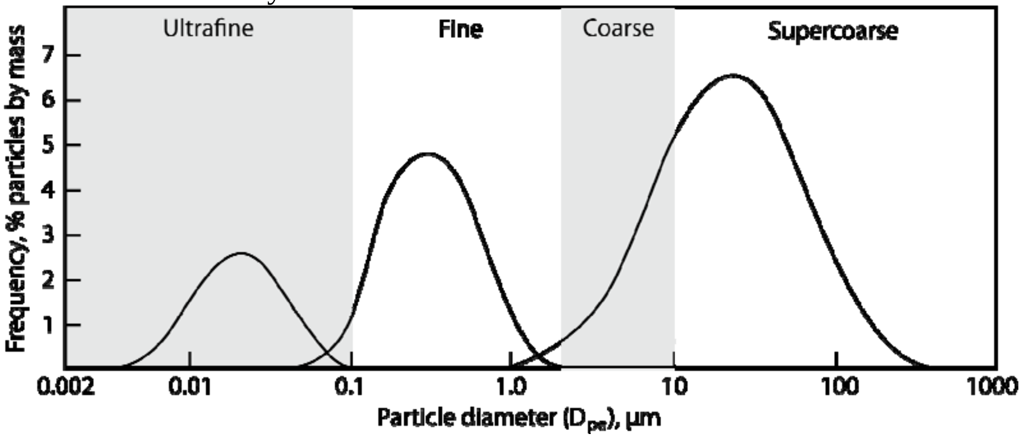

Figure C-4. Particle size categories used to classify particles (http://www.epa.gov/apti/bces/module3/category/category.htm)

Table C-1. Particle size, number of particles, and surface area[1] (http://www.epa.gov/apti/bces/module3/category/category.htm)

Total Mass	Diameter of Particles (µm)	Number of Particles (Approx. In millions)	Total Surface Area (cm²)	(m²)
1.0 gm	1,000	0.002	60	0.006
	100	2	600	0.06
	10	2,000	6 000	0.6
	1	2,000,000	60,000	6
	0.1	2,000,000,000	600,000	60

(1) Based on density of 1.0 gm/cm³

Figure C-5 provides a comparison of the mass distribution and particle number distribution. As the particle size decreases the number of particles in the size fraction increases. In addition, as illustrated in Table C-1, the surface area increases significantly with decreasing particle resulting in the opportunity for reactive gases such as sulfur oxides to react forming sticky phases that bond particles together.

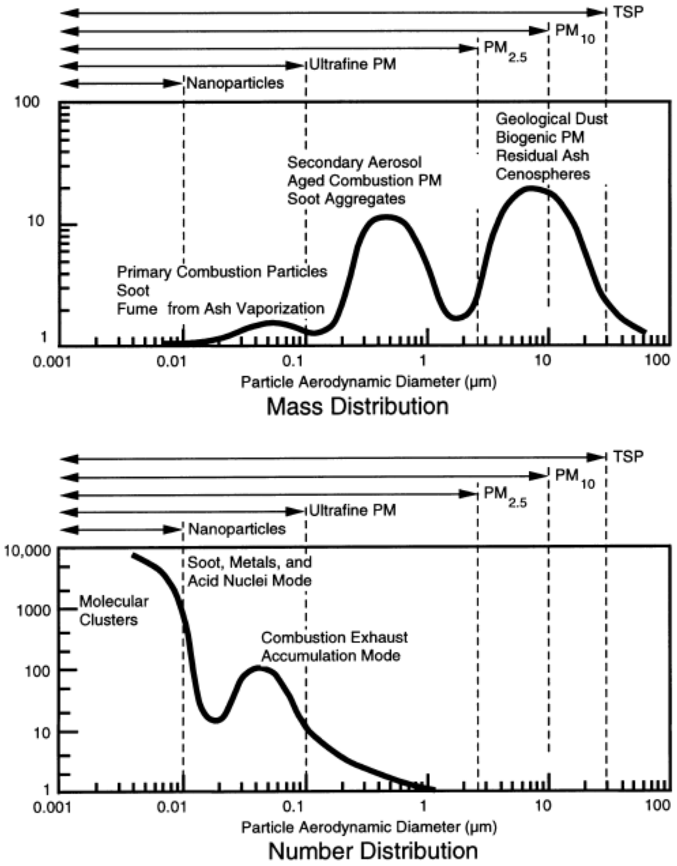

Figure C-5. Comparison of mass distribution and particle number distribution for combustion derived particles and aerosols (Lighty and others, 2000).

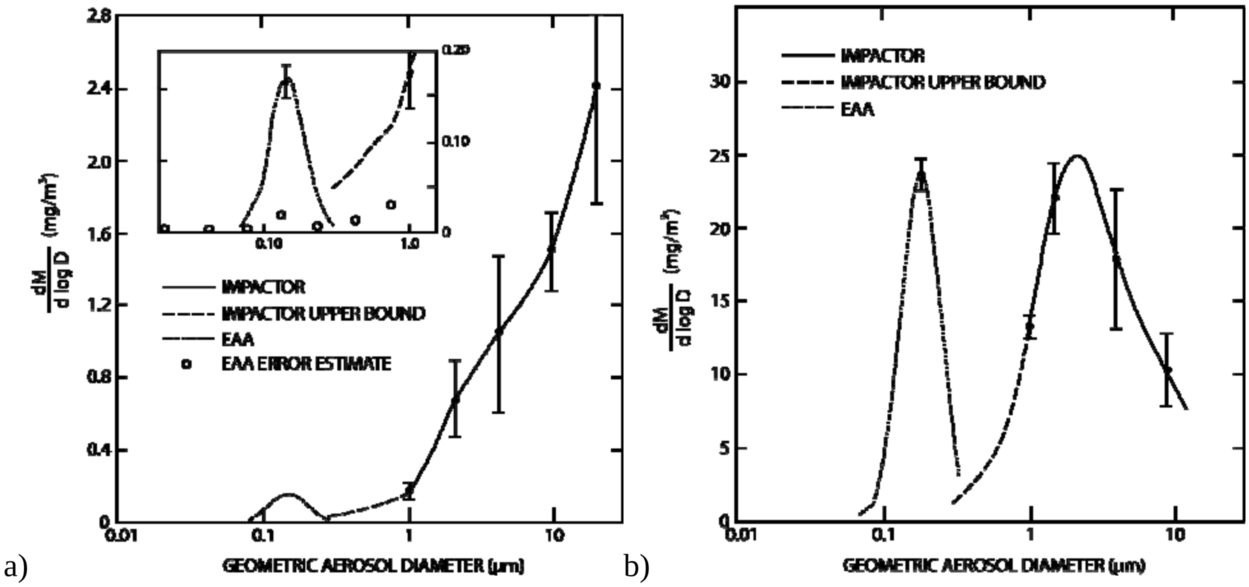
Particle size distributions for fly ash collected upstream and downstream of an ESP are illustrated in Figure C-6. This work was conducted by Markowski and others (2000) specifically aimed at characterizing the submicron aerosol mode of fly ash formation.



a) b)

Figure C-6. Typical differential mass distributions of particulate collected a) upstream and b) downstream of an ESP (Markowski and others, 2000).

Fly ash produced upon the combustion of high sodium lignites in a pulverized coal (PC) fired system shows significant enrichment of sodium in the smaller size fractions as shown in Figure C-7. This figure illustrates the increase in the sodium content in the finer size fractions of ash as a result of firing high sodium lignite. The sodium and sulfur content of the less that 3 micrometer size fraction of the sampling train approached 20% Na_2O, and 25% SO_3. The form of the sodium is likely sodium oxide and sulfate.

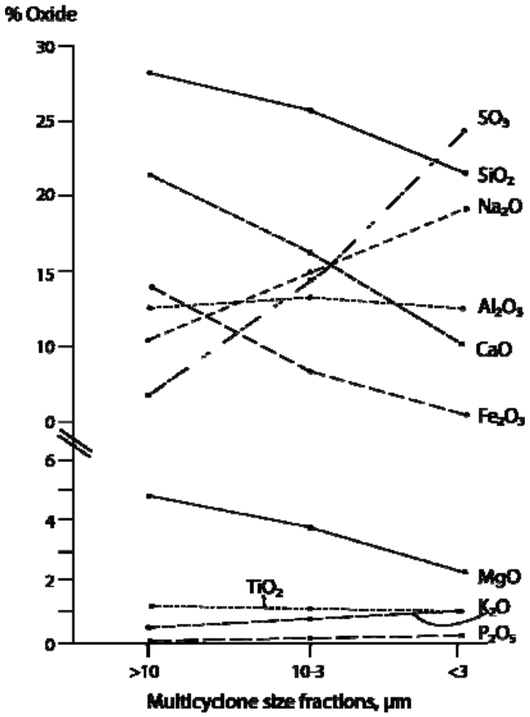


Figure C-7. Composition distribution of ash particles during combustion of North Dakota Lignite (Benson and others, 1984).

Electrostatic precipitator collection efficiency

The classical curve for ESP particle collection efficiency is shown in Figure C-8. This curve is typical of well behaved ash materials that do not present significant problems in collection. The collection efficiency is very good for particles greater than 5 to 10µm and the collection efficiency decreases with decreasing particles size with minimum collection efficiency between 0.2 to 2 µm in diameter. The collection efficiencies vary significantly because of particle size and composition.

Low collection efficiency for difficult to collect particles is between 0.1 to 1 µm in particle diameter. Figure C-9 provides an illustration of the range of collection efficiencies. Based on EPA education modules, no air pollution control device shows high collection efficiency in this range (0.1 to 1.0 µm) due to inherent limitations of the collection devices and particle characteristics (http://www.epa.gov/apti/bces/module3/collect/collect.htm). The following mechanisms of particle capture are impacted by the size of the particles:

- Inertial impaction and interception
- Brownian diffusion
- Gravitational settling
- Electrostatic attraction
- Thermophoresis
- Diffusiophoresis

The EPA (http://www.epa.gov/apti/bces/module3/collect/collect.htm) has indicated that based on a number of studies of actual "*sources stationary sources generating high* *concentrations of particles in the 0.1 to 0.5 micrometer range may be an especially challenging control problem. … The gap is most noticeable in wet scrubbers and electrostatic precipitators.*" A generalized plot showing the range of collection efficiencies is shown in Figure C-9. Overlaid on the diagram is the mass size distribution of particles collected downstream of the ESP wet FGD at the MRY plant (Markowski and others, 1983). This shows that ash produced in the MRY plant have a particle size that can pass through the scrubber and that these particles are rich in sodium as shown in Figure C-7.

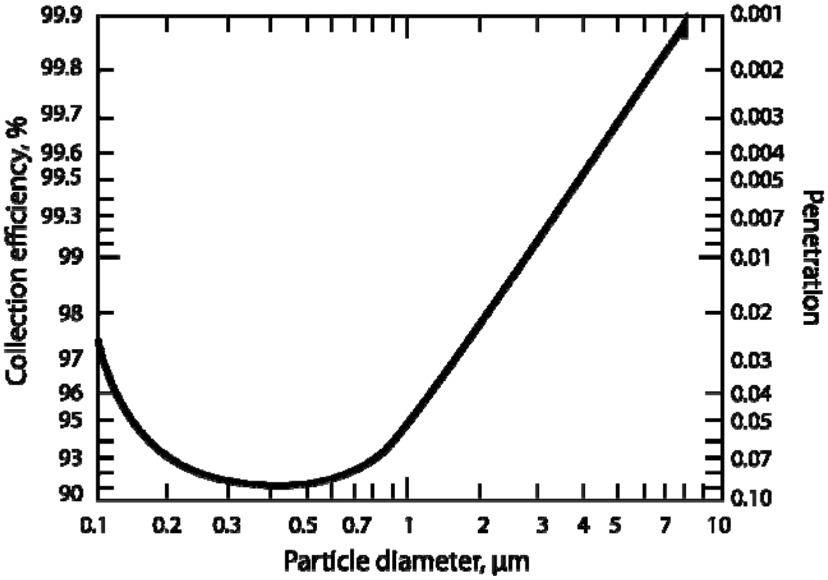

Figure C-8. Typical ESP Collection efficiency curve for removal of particulate from gas streams (http://www.epa.gov/apti/bces/module3/collect/collect.htm).

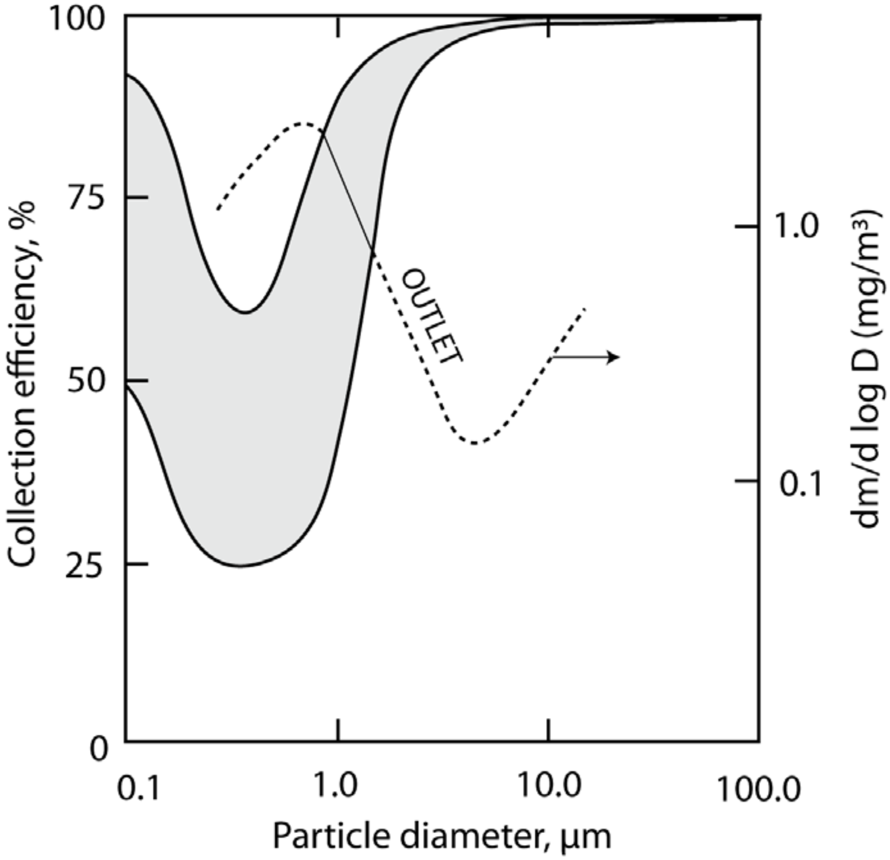

Figure C-9. Particulate control efficiency for difficult to control particulate combined with the mass distribution of particulate collected downstream of the scrubber at MRY (Markowski and others, 1983, http://www.epa.gov/apti/bces/module3/collect/collect.htm)

Field Experience and Testing

As indicated by EPA (Woodward, 1998), scrubbers do not effectively remove particulate less than 1µm in diameter. There is significant evidence that sodium-rich aerosols penetrate ESPs as well as scrubbers at full-scale power plants when firing high-alkali-containing fuels. An example is a biomass fired system using a tower type scrubber where the removal efficiency of the smaller size fraction of ash is low, as shown in Figure C-10 (Ohlström and others, 2006).

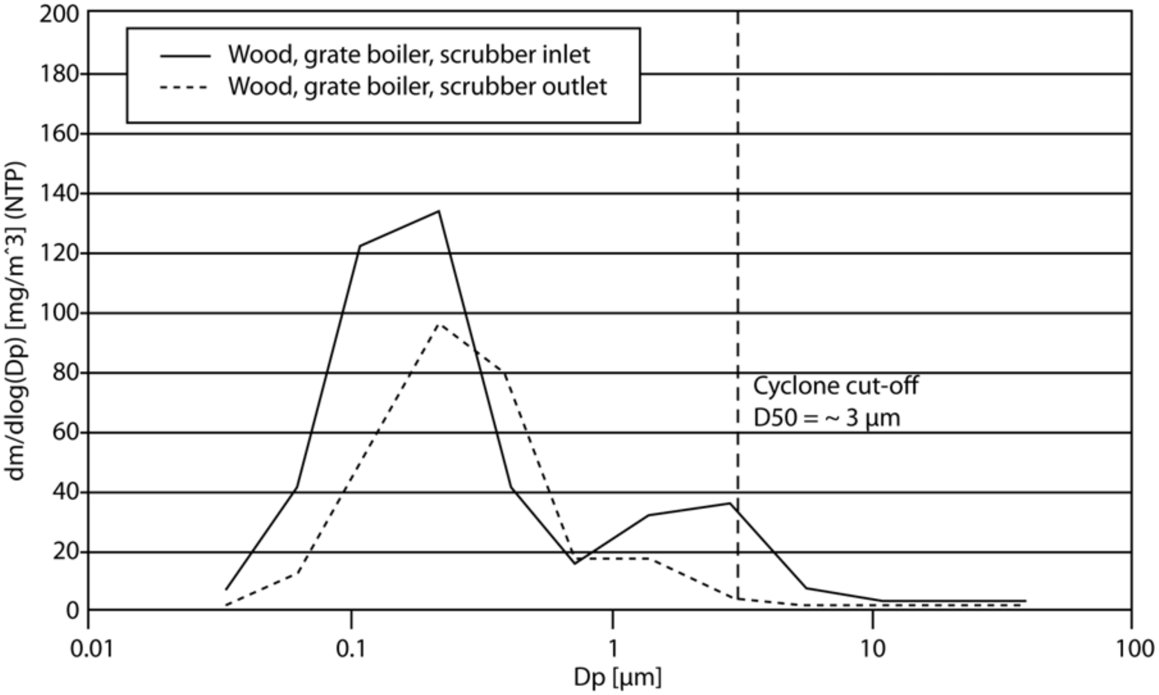

Figure C-10. Removal of fine aerosols using a scrubber on a wood fired combustor (Ohlström and others, 2006).

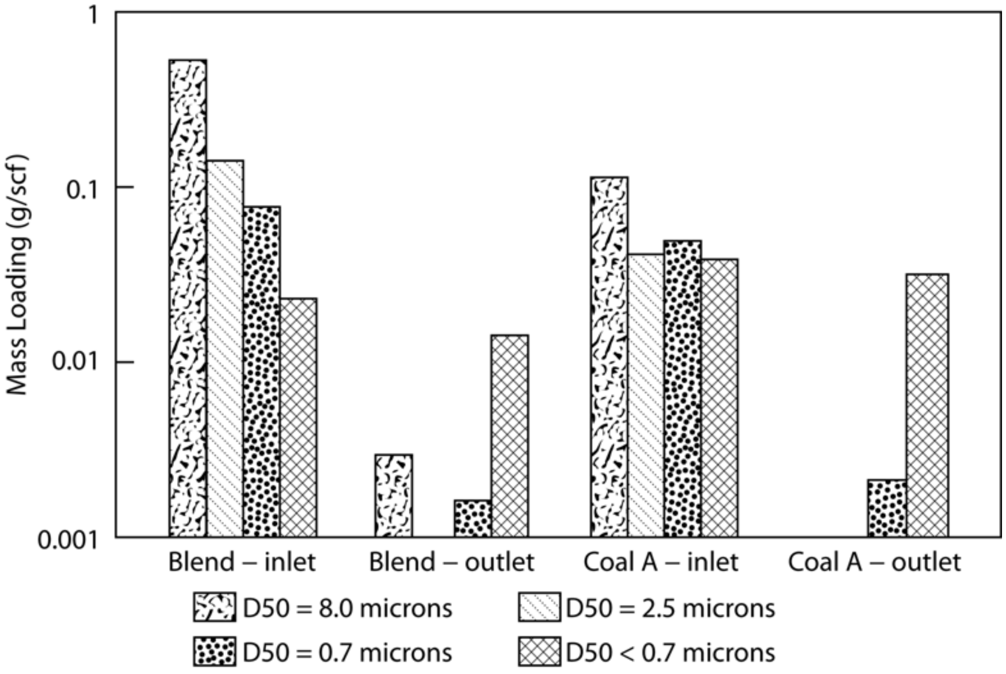
Minnesota Power's Boswell Energy Station found that when it fired high-sodium, lower-ash northern Powder River Basin subbituminous coal (7% Na_2O in the ash), it experienced increases in opacity. Hurley and Katrinak (1992) conducted a field-testing project on Unit No. 4, a pulverized coal-fired boiler equipped with a venturi wet scrubber, to better understand the reasons for the opacity problems. During the field testing, sampling of the coals, flue gases, and scrubber materials was conducted. The particulate in flue gases downstream of the scrubber was aerodynamically classified using multicyclone followed by an impactor and a Nucleopore filter. The sized fractions were weighed and analyzed to determine the abundance and composition of the submicron-sized fractions. The mass loadings in the various size bins are plotted in Figure C-11, showing that the scrubber is quite effective in removing the larger particles. However, the scrubber is not very effective in removing the aerosols less than 1 micrometer in diameter for both the blended coal and the high sodium coal (Coal A).

The results of the study indicated that the particulate collected downstream of the scrubber was coal-related and caused by the high sodium content of the coals. Vapor-phase sodium condenses in the boiler's convective pass to form fine sodium-rich aerosols or other Na species that later react with ash particles. Pure Na_2SO_4 particles are too small to be removed by such scrubbing. Figure C-12 shows the spikes of the ash material collected on Stage 10 of the impactor. This impactor accumulation represents particles of less than 0.7 to 2.5 micrometer size fraction of the submicron aerosol. The spikes are made up of submicron particulate matter, and the chemical analyses of the spikes and ash particles collected on the Nucleopore filters downstream of the impactor plates are shown in Table C-4. Both samples are dominated by sodium and sulfur that are likely in the form of sodium sulfate. These sulfate materials exhibit highly cohesive tendencies.



Overall mass size distributions for entrained ash samples.

Figure C-11. Mass loadings and size for particulate collected upstream and downstream of the wet venturi scrubber at Clay Boswell (Hurley and Katrinak, 1992).

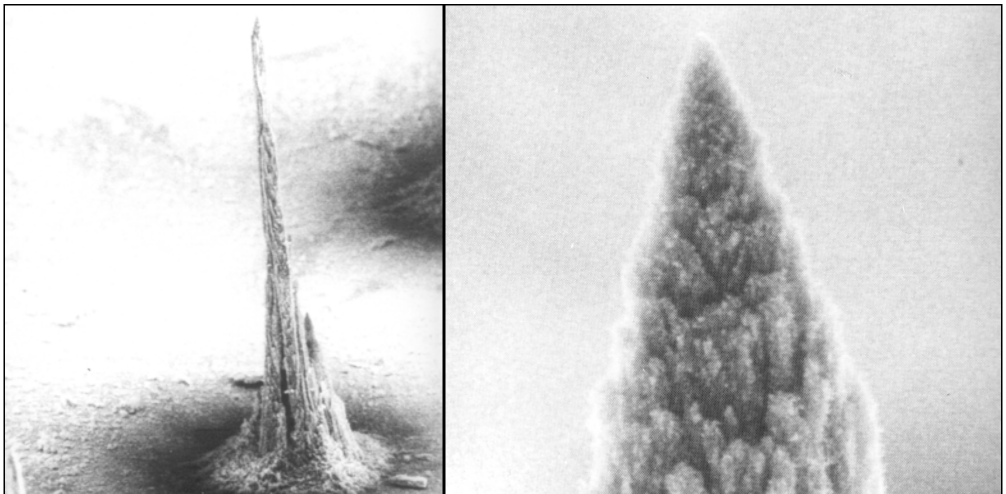


Figure C-12. Scanning electron microscope images of spike formed on impactor plate upon combustion of high-sodium subbituminous coal (right - close-up of spike) (Hurley and Katrinak, 1992).

Table C-4. Chemical Composition of the Spike Shown in Figure C-12 and the Filter (weight percent expressed as equivalent oxide).

	100% Coal A	
Oxide	**Spike**	**Filter**
Na_2O	**35.1**	**17.3**
MgO	1.4	7.8
Al_2O_3	2.0	9.8
SiO_2	9.1	10.6
P_2O_5	0.4	0.2
SO_3	**39.7**	**28.0**
K_2O	2.6	1.5
CaO	6.2	15.7
TiO_2	0.2	1.8
Cr_2O_3	1.4	0.1
Fe_2O_3	0.9	2.9
BaO	0.5	2.6

In addition to the aforementioned testing results, penetration of submicron particles through ESP and scrubbers has been reported by numerous researchers (Markowski and others, 1983, and Lighty and others, 2000).

Power Span Testing at MRY

Aerosols passing through the ESP at MRY Unit 1 resulted in significant accumulation on Powerspan's ECO barrier discharge reactor resulting in significant degradation in performance. The ECO DBD reactor is located just downstream of the plant's ESP or fabric filter (FF) and can be exposed to aerosols. The DBD reactor has quartz electrode rods inside where electric current is passed in order to generate the plasma used to oxidize NO. The temperature of the flue gas at the DBD reactor ranged between 300°F and 350°F. The temperature of the quartz electrodes is approximately 100°F higher than the gas temperature.

The Powerspan ECO reactor slip stream system was designed by Powerspan and the EERC. The slip stream system was installed by the EERC at Minnkota Power Company's Milton R. Young Station Unit #1 down stream of the ESP where the flue gas temperature was ranged from 300°F to 350°F. The system was commissioned on July 3, 2007, operated for 107 days. Operational performance of the system was monitored and data were archived for post processing. A pair of electrodes were extracted and replaced on a bi-weekly basis. Each pair of electrodes were shipped to Powerspan for testing in their laboratory reactor. Tested electrodes were then shipped to the EERC for scanning electron microscopy imaging and x-ray microanalysis. Measurement of NOx conversion by the slip stream system was not possible due to the nitric acid production of the DBD reactor.

The operational observations, performance results, and lab testing showed that the system was adversely affected by ash fouling. NOx conversion by ash covered electrodes was significantly reduced. Figure C-13 compares rods exposed to flue gas and aerosols downstream of the ESP at MRY Unit 1. The abundance of sodium in coal fired during the Powerspan testing is shown in Figure C-14. The results show sodium levels measured by the full stream elemental analyzer (FSEA) ranged from 3.5 to 6 % Na2O in ash. Figure C-15 shows the degradation in NO conversion as a result of being coated with aerosols. The NO conversion was severely impacted.

Figure C-13. Comparison of (left) clean quartz rod and (right) dirty quartz rod exposed to flue gas downstream of ESP at MRY Unit 1 for sixteen days.

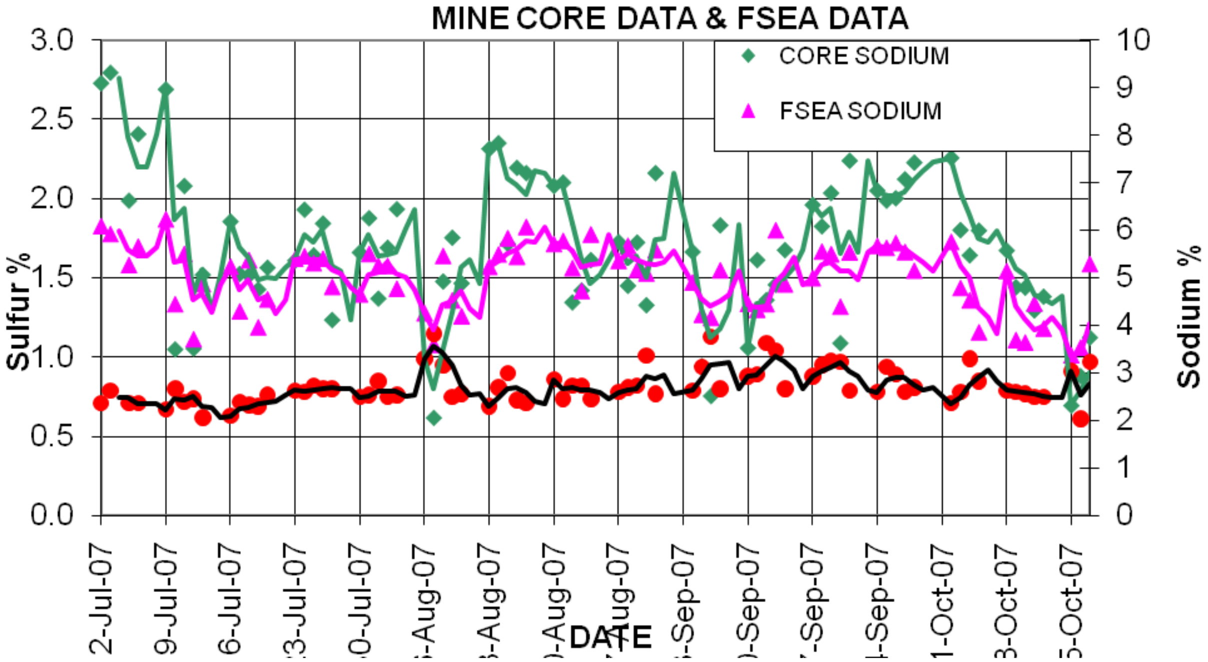

Figure C-14. Sodium and sulfur levels in lignite delivered during testing of the Powerspan barrier discharge reactor.

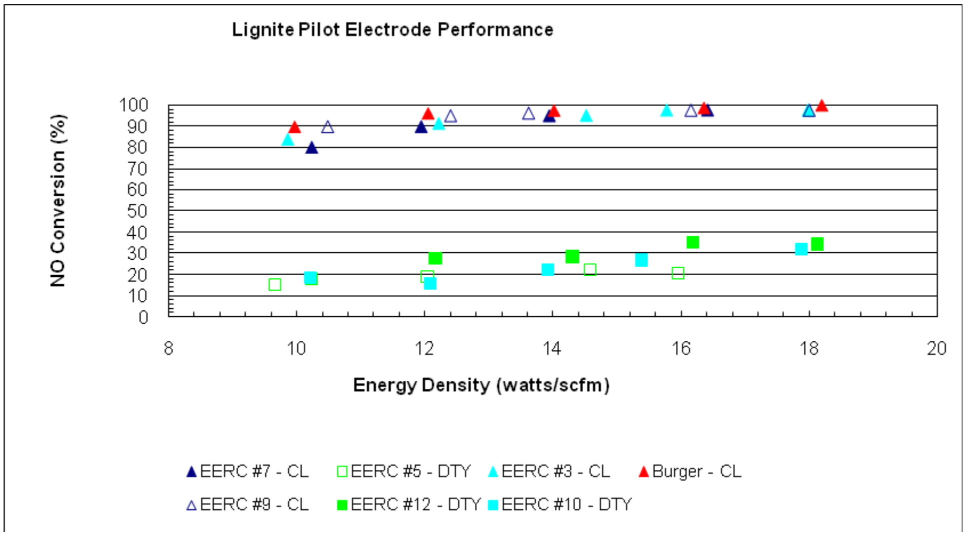

Figure C-15. NO conversion for clean (CL) and dirty (DTY) for quartz tube exposed the flue gas during the MRY testing.

Examination of the quartz rods (cross-sectioned to expose coating thickness) using scanning electron microscope elemental analysis showed significant elemental sodium, sulfur, and calcium in the ash coating the tubes after only 16 days of testing. The data is reported on Figure C-16. The thickness of the layer was approximately 25 µm. The rods were exposed to sootblowing. Images of the reactor and coatings on the electrodes are shown in Figure C-17.

Figure C-16. SEM point analysis on electrode #11 (16 days of service).

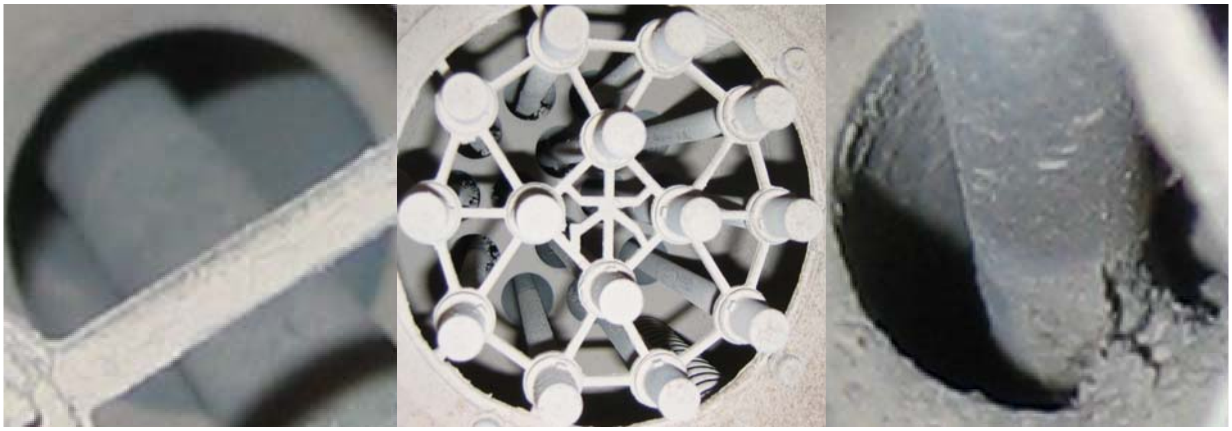

Figure C-17. Images of top of DBD reactor showing ash accumulations on electrodes and reactor surfaces.

Conclusions gained by this work were:

1. Sodium rich aerosols and small ash particles that had penetrated the ESP accumulate and become bonded on the surface of the silica electrodes in spite of soot blowing using a sonic horn as recommended by Powerspan.
2. Ash accumulations adversely affected the NOx conversion.
3. The adverse impact occurs within a two week time period.

MRY Sulfate Aerosol Sampling

The penetration of aerosols through ESP and wet scrubbers is well known and has been studied since the mid 1970s (McCain and others, 1975; Ensor and others, 1975). As a result of these challenges, the quantity of total aerosols and sulfate aerosols was measured at the MRY by Markowski and others, 1983. Markowski and others (1983) collected EPA Method 17 particulate samples and size-segregated the particles using an impactor (aerodynamically separates particles and allows for the characterization of each fraction). The results of the EPA method 17 sampling (mass concentration) conducted over a four-day period are illustrated in Figure C-18 for the inlet and outlet of the scrubber. At the inlet, aerosol mass concentrations ranged from a high of more than 10,000 µg/m^3 to a low of 4,000 µg/m^3. Significant levels were also found at the scrubber outlet, ranging from 8,800 to 2,500 µg/m^3. The removal efficiency varied from -25 to 66%.

Markowski and other (1983) offered no explanation of the differences in the levels of aerosols measured in the flue gas and removal efficiency. They did not consider that the ash content of the coal varied significantly during the testing. Results of testing at MRY have shown significant differences in the quantity vaporized for coals that have different ash contents (see Figure C-3). The variations in ash content shown in Figure C-18 reflect changing coal characteristics that resulted in differences in aerosol mass concentration.

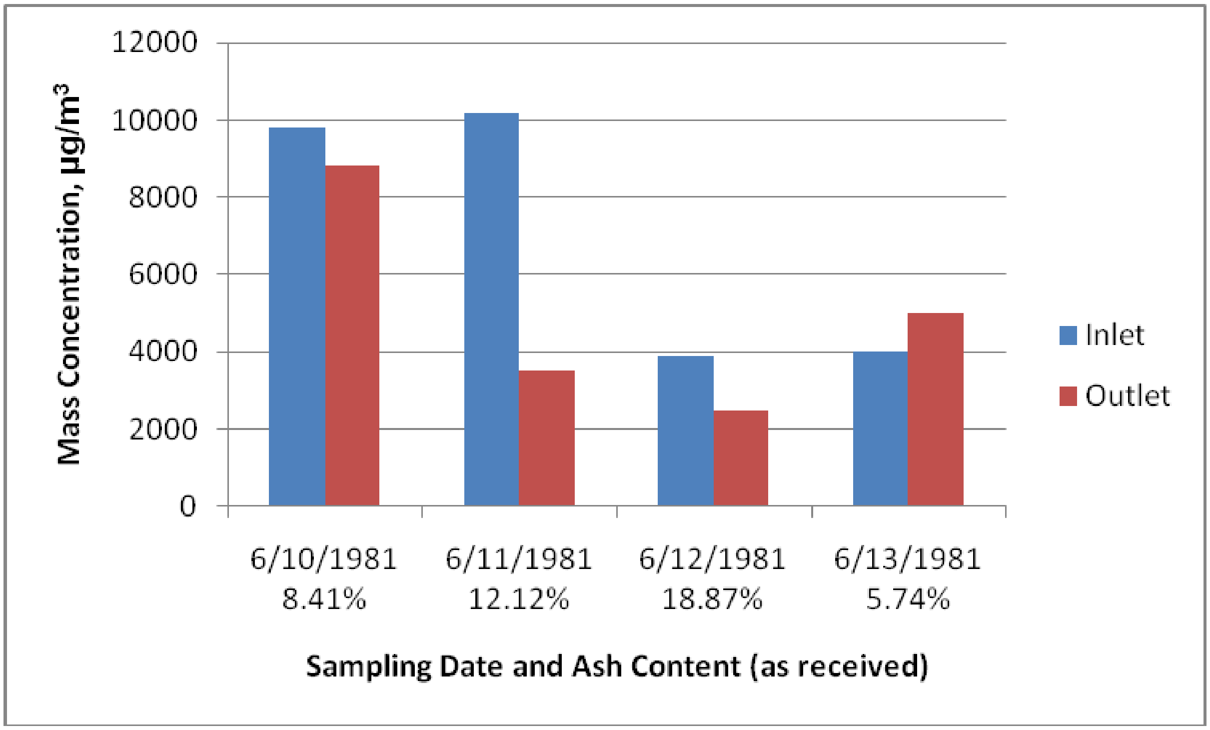

Figure C-18. Mass Concentration of Aerosol Collected at MRY Unit 2 at the Scrubber Inlet and Outlet (Markowski and others, 1983).

The results of the measurements of aerosol capture are illustrated in Figure C-19. The results show that aerosols less than one micrometer in diameter are not effectively captured in the wet FGD at the MRY facility. The graph also indicates the penetration of the particles through the FGD as a function of particle size. The penetration is the outlet size distribution divided by the inlet size distribution. (*Note: Penetration = 1- efficiency*). Markowski and others (1983) showed that the "metallic" sulfate aerosols (sodium sulfate) penetrated the FGD much more effectively than the larger particulate materials.

The mass of each of the impactor size fractions for the aerosols collected at the inlet and the outlet of the wet FGD upstream and downstream of the scrubber are illustrated in Figure C-20 and 21 with the results tabulated in Table C-5. The total mass distributions are summarized in Figure C-20 and the sulfate mass distribution is illustrated in Figure C-20.

Based on the impactor data the total mass of particulate that penetrates the scrubber is 5990 µg/m^3 (Markowski and others, 1983). These ash materials consist of a combination of sulfates and oxides of sodium, calcium, and sulfur. Much of the aerosol is present in the >14 µm size fraction. There are also significant mass in the less than 1 µm size fraction. All of these particles have the potential to penetrate the pores of the catalyst. In addition, there is a significant mass in the <0.26 µm fraction. This fraction represents the ultrafine component that has been implicated as the most significant contributor to catalyst poisoning (Kling and others, 2007).

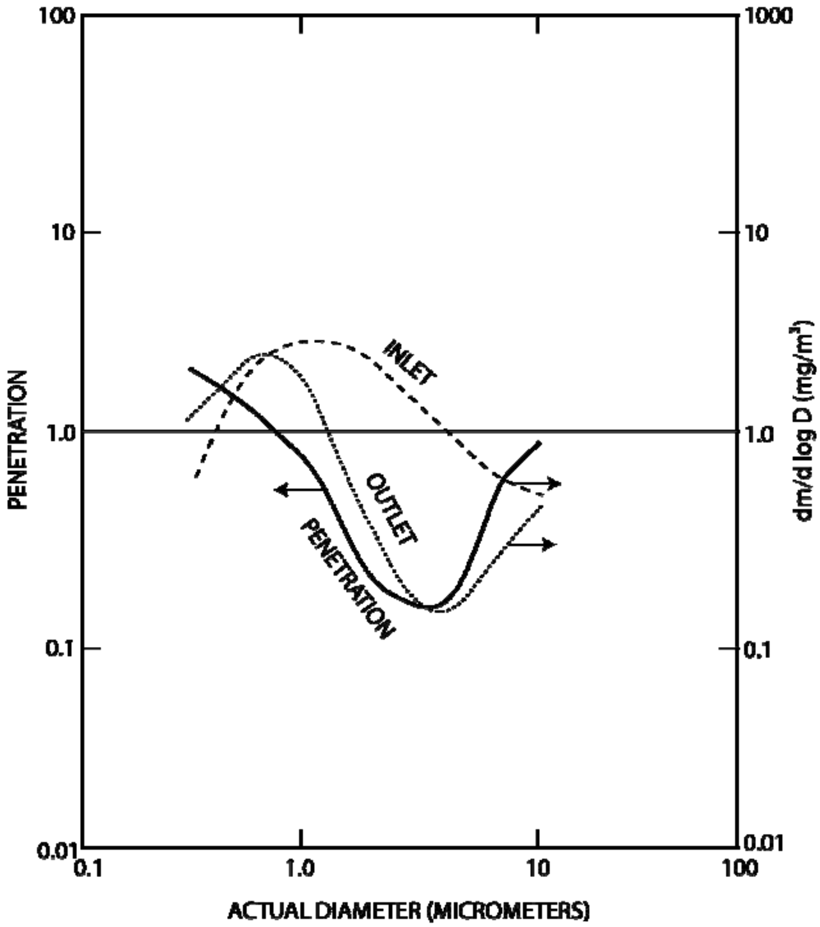

Figure C-19. Penetration through the wet scrubber (Markowski and others, 1983).

Table C-5. Size-segregated total and sulfate particulate collected upstream and downstream of the MRY FGD. (Markowski and others, 1983).

	Inlet	**Outlet**	**Inlet**	**Outlet**
Size, µm	Total, µg/m^3	Total, µg/m^3	Sulfate, µg/m^3	Sulfate, µg/m^3
<0.26	1910	769	436	602
0.26-0.52	401	640	164	274

Figure C-21. Sulfate particulate removal across scrubber at MRY.

Estimation of Alkali Aerosol Loading and Catalyst Deactivation

The following data was used to estimate alkali aerosol loading and catalyst deactivation. The particle loading was based on the results of testing conducted by Markowski and others (1983) where they determined the mass loadings of aerosols at the inlet and outlet of the wet FGD at MRY Unit 2. The key data utilized is illustrated in Figure C-22 to estimate the loadings. The data provided shows a range of mass concentrations up to 8,800 µg/m^3 at the outlet of the scrubber. Based on results in mass size distribution of the aerosol 47 to 80% of the aerosols that pass through the scrubber is less than 1.1 µm. Much of this material is in the ultrafine fraction.

These materials have the potential to penetrate into the catalyst causing plugging and can react with active components in the catalyst. There are numerous publications supporting these mechanisms. Kling and others(2007) found that the rate of catalyst deactivation was related to the accumulation of sodium and potassium on the catalyst as shown in Figure C-23 and 24. The work by Kling and others (2007) is consistent with the work conducted by Khodayari (2001) illustrated in Figure C-25 where it was shown that the deactivation rate is more significant for PC fired systems as compared to fluidized beds. The work based on Kling and others when applied to PC- and cyclone-fired systems will likely underestimate the degree of deactivation because of the firing methods.

Table 4 – MRYS Unit Design and Operating Parameters

Design Unit Operating Characteristics(1)	**Unit 1 Design**	**Unit 2 Design**
Boiler Type	Cyclone	Cyclone
Boiler Manufacturer	B&W	B&W
Boiler Design Heat Input Capacity (nameplate), mmBtu/hr	2,510	4,696
Unit Nameplate Generator Output Capacity, MW_g (gross)	257	477
Unit Nominal Full Load (NFL) Output, MW_g (gross)	235	450
Boiler Heat Input for Unit NFL Output, mmBtu/hr	2,508	4,814
Boiler Excess O_2, %, (wet, NFL)	3.17	4.04
Boiler Excess Air, % (NFL)	21.3	28.5
Fly Ash Portion of Total Ash, % (NFL)	45	50
Typical Maximum Continuous Rating (MCR) output, MW_g	253	462
Maximum Unit Output (URGE) Rating, MW_g	278	512
Boiler Firing Conditions for Flue Gas Flow Calculations:		
Boiler Heat Input, mmBtu/hr	2,852	4,740
Coal Higher Heating Value, Btu/lb as-received	6,578	6,578
Coal Flow Rate for heat input, lb/hr	433,500	720,500
Fly Ash Portion of Total Ash, %	50	50
Flue Gas Conditions at the boiler flue gas outlet:		
Boiler Excess O_2, %, (wet)	2.87	4.77
Boiler Excess Air, %	19.0	35.4
Flue Gas Mass Flow Rate, lb/hr	3,811,000	7,117,000
Flue Gas Volumetric Flow Rate, acfm	2,502,000	4,371,000
Flue Gas Temperature, degrees F	910	818
Flue Gas Pressure, in. w.g.	-11.5	-13.5
Boiler Outlet Maximum SO_2, lb/mmBtu	3.0(2)	3.0(2)
Boiler Outlet Maximum SO_2, lb/hr	8,970	15,474
Average Boiler Heat Input for SO_2, mmBtu/hr	2,990	5,158
Expected Boiler Outlet Maximum 30-day average SO_3, lb/hr	135(3)	236(3)

(1) – Boiler unit operating parameters are provided for more than one load or output condition.

(2) – Boiler Outlet Maximum SO_2 lb/mmBtu is based on 1.0% S and 6,578 Btu/lb higher heating value content in the as-received lignite coal.

(3) – Boiler Outlet Maximum SO_3 lb/hr is based on the assumed conversion of 1.5% of the boiler outlet SO_2 to SO_3 upstream of any flue gas treatment. This conversion percentage has not been confirmed by actual boiler outlet flue gas test measurements. The SO_2 lb/mmBtu and lb/hr values have not been reduced by this assumed SO_3 conversion.

Table C2 summarizes the average, maximum and minimum values for the entire as-fired coal database. The ranges on the various components can be very large. For example, the ash content ranges from 5 to 25%. Sodium oxide content ranges from 0.6 to 13% of the ash.

Table C2. Average, maximum, and minimum of basic coal analysis for all the coals in the as-fired database - Center Lignite Coal

1. Ash weight percent was determined on an “as-fired” lignite coal basis.
2. BTU (higher heating value) content expressed on an “as-fired” lignite coal basis.
3. Constituent weight percent of the ash, elemental weight percent expressed as equivalent oxide.
4. B/A is the base to acid weight ratio of the ash constituents (B/A=[Na_2O+MgO+CaO+ K_2O+FeO]/[SiO_2+Al_2O_3+TiO_2]).

Subject: Minnkota SCR Catalyst Recommendations

Attachments: Scope of Services 26Aug09.doc; Report 1084 - Particulate - FINAL 8-20-09.pdf; MRY SCR Vendor Query (4-18-07) - Abbreviated.pdf

Noel

Minnkota Power is requesting recommendations on SCR catalyst design for low-dust and tail-end applications as discussed in our offices on August 11.

Attached are the following documents for your consideration:

1. Scope of Services 26Aug09
2. Report 1084 - Particulate - FINAL 8-20-09
3. MRY SCR Vendor Query (4-18-07) – Abbreviated

The first document summarizes items Minnkota Power is requesting in support of the required BACT.

The second document is flue gas testing data performed at the Milton R. Young Station. This information should be treated confidential.

The third document includes some basic boiler operating parameters and was extracted from the MRY SCR Vendor Query originally transmitted in April of 2007.

Please contact us if you need any additional information or would like to discuss the project.

Thank you for your assistance.

Scope of Services
SCR Catalyst Recommendations

Minnkota Power Cooperative
Milton R Young Station
August 26, 2009

1. Minnkota Power Cooperative (MPC) operates two coal-fired electric generating units at the Milton R. Young Station. Both units are Babcock & Wilcox balanced-draft cyclone fired boilers burning 100% North Dakota lignite coal supplied from an adjacent mine. Unit 1 has a gross design output capacity of 257 MW and was initially placed into commercial service in 1970. Unit 2 has a gross original design output capacity of 477 MW and was initially put into service in 1977. The units are located approximately 40 miles northwest of Bismarck, ND.

2. MPC is performing a SCR cost estimate for both units as part of a NO_X BACT Study required by the North Dakota Department of Health. Because of the unique characteristics of North Dakota lignite, MPC is requesting assistant with SCR catalyst selection and sizing.

3. The scope of services MPC is requesting includes the following for both low dust and tail end SCR applications for both units:

   a. Size the reactors to provide the optimal gas velocity and NO_X reduction for the specific applications.

   b. Provide anticipated guarantees for NO_X reduction for the specific applications. Nominal anticipated NO_X concentration entering the reactors is 0.5 lb/million Btu. Nominal desired maximum NO_X concentration exiting the reactors is 0.05 lb/million Btu.

   c. Provide anticipated guarantees for ammonia usage and ammonia slip for the specific applications. The maximum ammonia slip should not exceed 5 ppm.

   d. Provide anticipated guarantees for catalyst deactivation rate and life (number of operating hours between catalyst replacement). It is desired to have a 3 year interval between catalyst layer change-out. If a 3 year interval is not achievable, provide the longest interval the catalyst vendor is able to guarantee.

   e. Provide budgetary pricing for the recommended catalyst.

   f. Review preliminary ductwork layout drawings to determine if any fatal flaws are apparent.

4. Additional design parameters and flue gas testing results are included as an attachment. It is the intent that Dr. Steve Benson and other team members will discuss the test data and related implications of the catalyst selection and design with the catalyst supplier.

5. Please provide requested items by September 18, 2009.

EXECUTIVE SUMMARY

Particulate sampling was conducted at Minnkota Power Cooperative's Milton R. Young plant to determine the particulate size and composition distribution of samples collected upstream of the ESP, upstream of the wet scrubber, and downstream of the wet scrubber. Emphasis was placed on determining the fate of sodium, potassium, and calcium since these elements can cause significant plugging and deposition problem.

During the testing, operating conditions of the plant were constant and there was no gas bypass. The coal fired during the testing remained relatively consistent. The as-received ash content ranged from 7.73 to 7.89%. Sodium oxide content of the ash ranged from 7.22 to 7.57% and the base-to-acid ratio decreased the last two days of testing (a result of a decrease in CaO content and an increase in SiO_2 and Al_2O_3 levels). Sampling upstream of the ESP and scrubber were conducted using a combination multicylones and impactors. The cyclones collected sized fractions of larger particles (greater than one to five microns) and the impactor collected the sub-micron particulate. Sampling downstream of the scrubber was conducted with a single cyclone followed by a 13-stage advanced impactor. In addition, the submicron particle number concentration was measured using a scanning mobility particle sizer (SMPS).

The results of the particulate mass information indicated a high loading at the ESP inlet of 4.96×10^6 µg/dscm, a scrubber inlet loading of 1.1×10^4 µg/dscm, and a scrubber outlet loading of 1.08×10^4 µg/dscm. These results show very little overall removal of the submicron particulate across the wet scrubber system. A significant fraction of the particulate was removed by the ESP, with a removal efficiency of 99.76%.

The size distribution of the particulate collected upstream of the ESP and upstream of the scrubber was multi-modal as summarized below:

- Upstream of the ESP there were at least three modes – a larger mode at 40 to 50 µm, a second mode at just under 10 µm, and third mode at about 1 µm. The larger particles are typically derived from mineral grains in the coal such as quartz, clays, and pyrite. The intermediate-sized particles are typically derived from small minerals and organically associated elements. The smaller mode (about one-micron and smaller) contains fine particles and condensed vapor phase species.
- Upstream of the scrubber there were two distinct modes – a larger mode between 8 to 10 µm and another mode centered at about 1 to 2 µm in diameter. The smaller mode is typically condensed vapor phase and small particles.
- Downstream of the scrubber, the primary mode centered at about 0.5 to 0.7 µm, and another possible mode occurred at 3 µm and larger.
- Particle number distributions were as follows:
    - Inlet to the ESP – between 1×10^7 to 10^8 particles per dry normal cubic centimeter (dncc);
    - Inlet to the scrubber is 10^5 particles/dncc;
    - Outlet of the scrubber 7×10^5 particles/dncc.

- Particle number distributions into the nanometer scale (1 µm = 1000 nm) was found to be as high as 10^5 particles/dncc.

Particle composition distributions of the particulate were determined for each of the major elements. The results were reported as µg/dscm of the element as illustrated in the Appendix and in the figures in the text.

- Upstream of the ESP the composition trends for sodium, potassium, calcium and sulfur showed greater concentrations of these elements in the particles that are smaller than 10 µm, with a significant increase in concentration in the flue gas at a particle size of less than 2 µm. There is another increase at 0.1 µm.
- Upstream of the scrubber the compositional trends for sodium, potassium, calcium and sulfur show higher levels at the 1 µm level. The ESP was effective in removing larger-sized particles, as well as some of the 0.1 µm particles. However, in the intermediate 1 µm particles, the ESP is not as effective in removing the particles.
- Downstream of the scrubber the composition size distribution determined for sodium, potassium, calcium and sulfur showed significant levels of sodium and sulfur in size fraction finer than 1 µm. The DLPI sampling system provides very accurate sizing data in the submicron size range. Other elements such as aluminum, silicon and iron show a significant depletion below 1 µm.

Comparison of the characteristics of the particles in terms of mass and composition indicate that, at the time of the testing, the total average mass of the particulate was about 10,800 µg/dscm. The particulate consisted mainly of sodium, potassium, and sulfur. The total quantity of sodium and potassium exiting was between 2000 to 3000 µg/dscm.

INTRODUCTION AND BACKGROUND

Microbeam Technologies, Inc. (MTI) teamed with Energy & Environmental Research Center (EERC) and the Chemical Engineering Department at the University of North Dakota (UND-ChE) to determine the abundance and composition of particulate materials produced at Unit #2 of Minnkota Power Cooperative's Milton R. Young Station (MRY), equipped with an electrostatic precipitator (ESP) and a wet flue gas desulfurization (FGD) system.

Very small particles or aerosols are produced upon combustion of all fuels. These particles have diameters less than ten microns, and in many cases less than one micron. They are formed during the combustion process - when the fuel is exposed to high temperatures and gaseous environments, impurities within the fuel are vaporized. When the gas is cooled, the vaporized species condense to form the small particles or aerosols.

Abundance and composition of the aerosols vary depending upon the fuel type and the combustion system. High-temperature combustion systems, such as cyclone-fired systems, produce higher levels of vaporized species than other combustion system types. Fuels (such as biomass or lignite) that contain high levels of alkali (sodium and potassium) and alkaline earth elements (calcium and magnesium) are especially likely to produce abundant aerosols in the cooler regions of combustion systems, such as air pollution control systems.

Collection of aerosol particles finer than five- to ten-microns in electrostatic precipitators and scrubbers is difficult because physical processes used by these technologies to capture particles are very limited in the one-tenth to five-micron size range. Detailed discussion of the processes can be found in the appendix of this report.

This report contains the results of analyses performed on coal and ash samples collected during field testing at MRY Unit 2. The work was performed to determine the properties (including size, mass, and composition) of particulates collected upstream and downstream electrostatic precipitator and wet FGD.

GOALS AND OBJECTIVES

Objectives of the project were as follows: 1) obtain representative, size-segregated samples of particulate material, including super- and sub-micron particulate, from three locations; 2) perform analyses on these samples to determine the size, mass, and composition distribution; and 3) provide an assessment of the probable impact of particulate inorganic species on the performance of NO_x reduction technologies.

SAMPLE COLLECTION AND CHARACTERIZATION

Sampling

Particulate material in the flue gas was collected and measured upstream and downstream of the MRY electrostatic precipitator, also denoted as the "air heater inlet" and at the wet flue gas desulfurization (FGD) or "scrubber inlet". Multi-cyclone samples were taken at the locations during the impactor testing. Sampling at the ESP inlet and scrubber inlet were conducted at single port locations and traversed for depth. The sampling at the ESP inlet was performed using two different ports; the total sampling time was divided equally between the selected sampling depths. The sampling depths, along with a summary of sampling activities, are summarized in **Table 1**. Sampling locations are shown on a simplified schematic in **Figure 1**.

Multicyclone Sampling

Size-fractionated fly ash samples were collected with a Southern Research Institute multi-staged multi-cyclone placed in the duct work at the air heater inlet (ESP inlet). The multicyclone consists of five cyclones, with decreasing d50 cut points, placed in series. The d50 particle size for each test is determined by the temperature and gas flow rate through the cyclone. For the testing at the MRY station, three of the five cyclone stages were used, along with the impactor, to collect selected coarser and finer fractions simultaneously. Size cut data for the multicyclone sampling performed at the air heater inlet are shown in **Table 2**.

Impactor Sampling

Size-fractionated fly ash samples were collected with a University of Washington seven-stage impactor placed in the gas stream behind the three multi-cyclone stages at the ESP inlet, and was used without multi-cyclone stages at the ESP outlet/scrubber inlet sampling location. The impactor is a round hole, multiple jet-type impactor with seven stages and a backup filter. Each stage has a decreasing d50 cut point. The d50 particle sizes for each test are determined by temperature and gas flow rate through the impactor. Cut points for the impactor at the air heater inlet are shown in **Table 2**. Cut points for the impactor at the scrubber inlet are shown in **Table 3**.

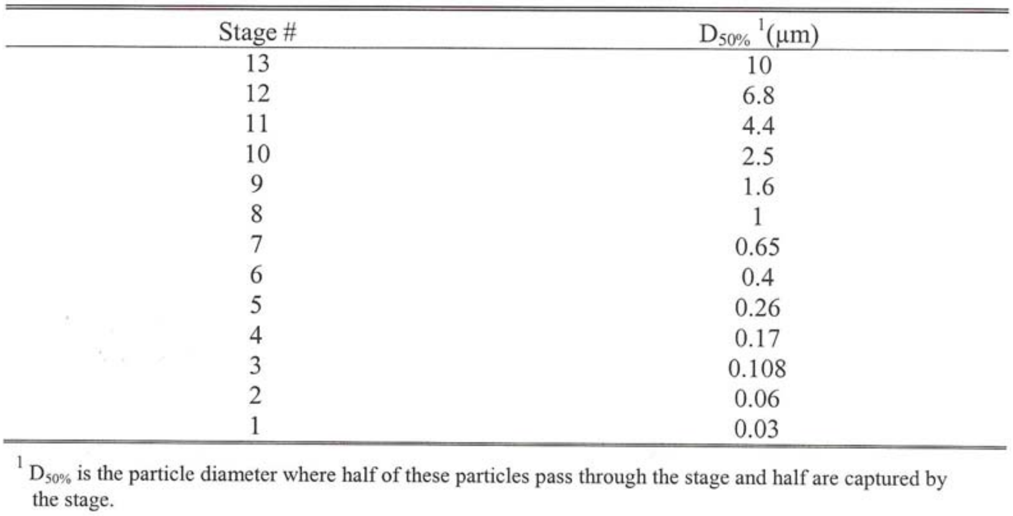
DLPI Sampling

The Dekati Low Pressure Impactor (DLPI) is a state-of-the-art 13-stage cascade impactor for measuring gravimetric particle size distribution of very small particles. It size-classified particles from 10 microns (µm) to 30 nm, and a filter stage accessory enables collection of particles smaller than 30 nm in diameter. **Figure 2** shows the impactor and stages. The d50 cut points for sampling with the DLPI are shown in **Table 4**.

Figure 2. Dekati Low-Pressure Impactor.

Table 4. D50 cut points for sampling (Dekati Low Pressure Impactor) at the B scrubber outlet.



Stage #	$D_{50\%}$ [1] (μm)
13	10
12	6.8
11	4.4
10	2.5
9	1.6
8	1
7	0.65
6	0.4
5	0.26
4	0.17
3	0.108
2	0.06
1	0.03

[1] $D_{50\%}$ is the particle diameter where half of these particles pass through the stage and half are captured by the stage.

SMPS Sampling

Sampling at the scrubber outlet was conducted utilizing the scanning mobility particle scanning (SMPS) system that consists of an electrostatic classifier (EC), a condensation particle counter (CPC), and data analysis center (DAC). A schematic of the system is shown in **Figure 3**. The EC classifies the particles, and the concentration is measured by the CPC. The DAC includes a personal computer with custom software, which controls individual instruments and performs data reduction. The components of the SMPS system, particularly the CPC, function normally at about 35°C (95°F). However, the EC does not appear to be too sensitive to temperature conditions.

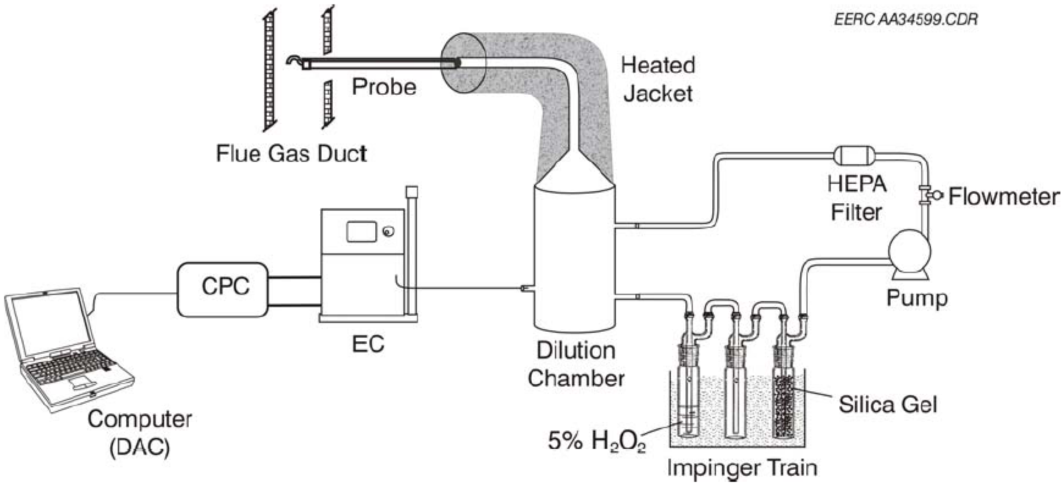


Figure 3. Schematic of the scanning mobility particle scanning (SMPS) system used at the B scrubber outlet.

The procedure for making particulate measurements with the SMPS system is conceptually simple, although manipulating the entire system is quite complex. Typically, flue gas enters the dilution chamber and is mixed with excess air fed through an external pump and at the flow rate of about 45–50 liters per minute (lpm). Dilution air from the pump passes through a HEPA filter to remove any particles that may be in the air. Part of the dilution air is sucked back from the dilution chamber and passed through an impinger train; the wet impinger contains about 250 milliliters (mL) of a 5% hydrogen peroxide (H_2O_2) solution, and the air is dried by passing it through a silica gel flask. The air from the flask is circulated through the pump back to the dilution chamber, and the recirculation process continues for the duration of the measurement. At the bottom of the dilution chamber, a ¼-inch line extracts a sample of the diluted flue gas and delivers it to the EC. The flow rates and pressure drop used in the EC are shown in **Table 5**.

Table 5. Electrostatic classifier (EC) flow meter set points.

Parameter	Monodisperse Air	Sheath Air	Excess Air
Flow Rate, lpm	0.3	3	3
Output, volts	2.305	2.735	2.627
Pressure Drop, cm H_2O	9	N/A*	N/A

* Not applicable.

Measurement does not begin until the CPC is running normally and flow is stable. At a typical working temperature of about 35°C (95°F), indicator lights are checked to ensure all parts are functioning properly (including the liquid level, laser, optics, pump flow, condenser, and saturator). The liquid used in running the CPC is n-butyl alcohol (n-butanol).

Analysis

Table 6 contains a full list of the samples collected and analyses performed. Samples collected were analyzed to determine chemical composition. Scanning electron microscopy with x-ray elemental analysis was performed on the ash samples. Information gained from this method included images and point and area (average) analyses. This type of analysis is called "morphology" because it combines image analysis for features of interest with chemical analysis.

The multicyclone samples were analyzed using bulk chemical anlaysis at EERC. The bulk analysis involved microwave digestion of the ash followed by inductively-coupled plasma-mass spectrometry (ICP-MS). Concentrations of the major elements sodium, potassium, phosphorus, calcium, magnesium and iron were determined.

The coal samples collected during the tests were composited for standard ASTM tests (proximate and ash composition or "mineral ash" analysis) and for computer-controlled scanning electron microscopy (CCSEM) analysis, which provides information on mineral types, abundance, and sizes within the coal.

RESULTS AND DISCUSSION

Coal Analysis and Plant Operating Conditions during Testing

The coal samples for each day were composited to form one larger sample; the four resulting composite coal samples were subjected to proximate and ash composition analyses. The results of the analyses are shown in **Table 7**. The coal was relatively consistent over the time period sampled. The as-received ash content ranged from 7.73 to 7.89%. Sodium content ranged from 7.22 to 7.57% and the base-to-acid ratio decreased the last two days of testing as a result of a decrease in CaO content and an increase in SiO_2 and Al_2O_3 levels.

Table 7. Proximate and ash composition analyses for four composite coal samples taken from MRY coal feeders on March 16 through 19, 2009.

Figures 4 and **5** show the overall coal flow rate, along with the ash quantity and base-to-acid ratio determined with the Full-Stream Elemental Analyzer (FSEA) during the test period. The FSEA data was corrected for a 23-hour lag time between filling the hoppers and feeding coal to the cyclones. These data show a decrease in the base-to-acid ratio during the testing period. This was observed in the analysis of the four daily composite samples.

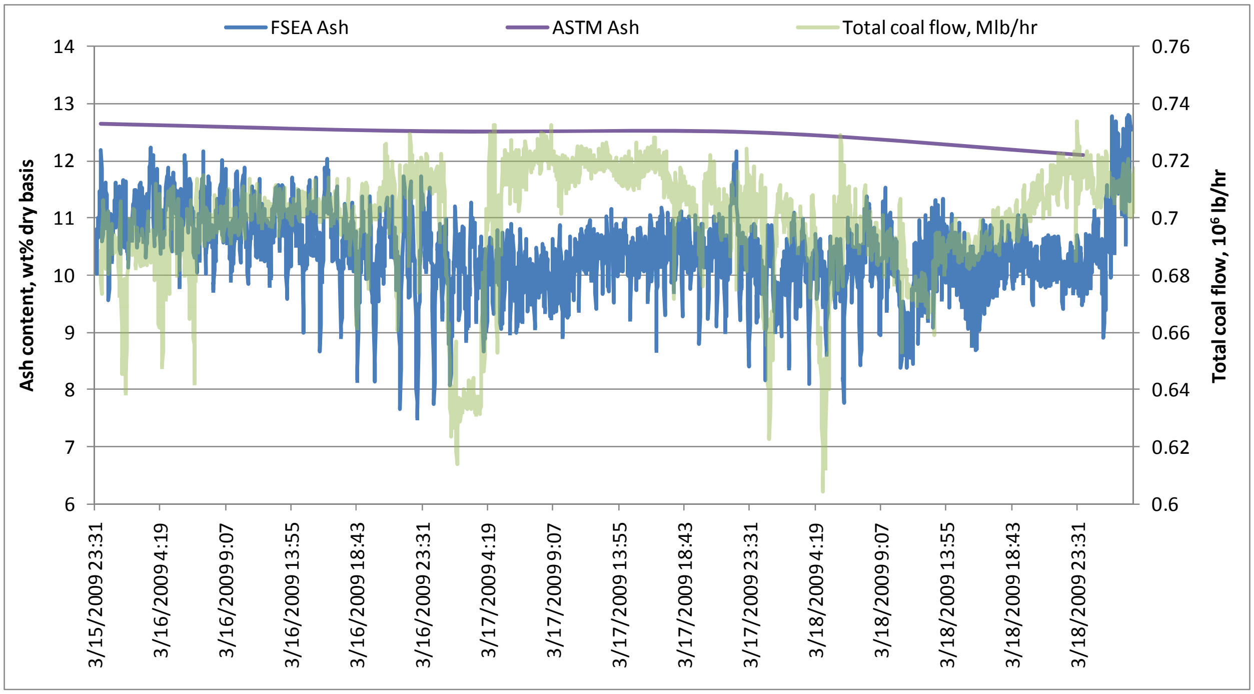

Figure 4. Coal belt flow and fuel ash quantity (determined with FSEA and by ASTM method on composite coal samples) during the testing. The FSEA data was corrected for a 23-hour lag time between filling the hoppers and estimated fuel fed to the cyclones.

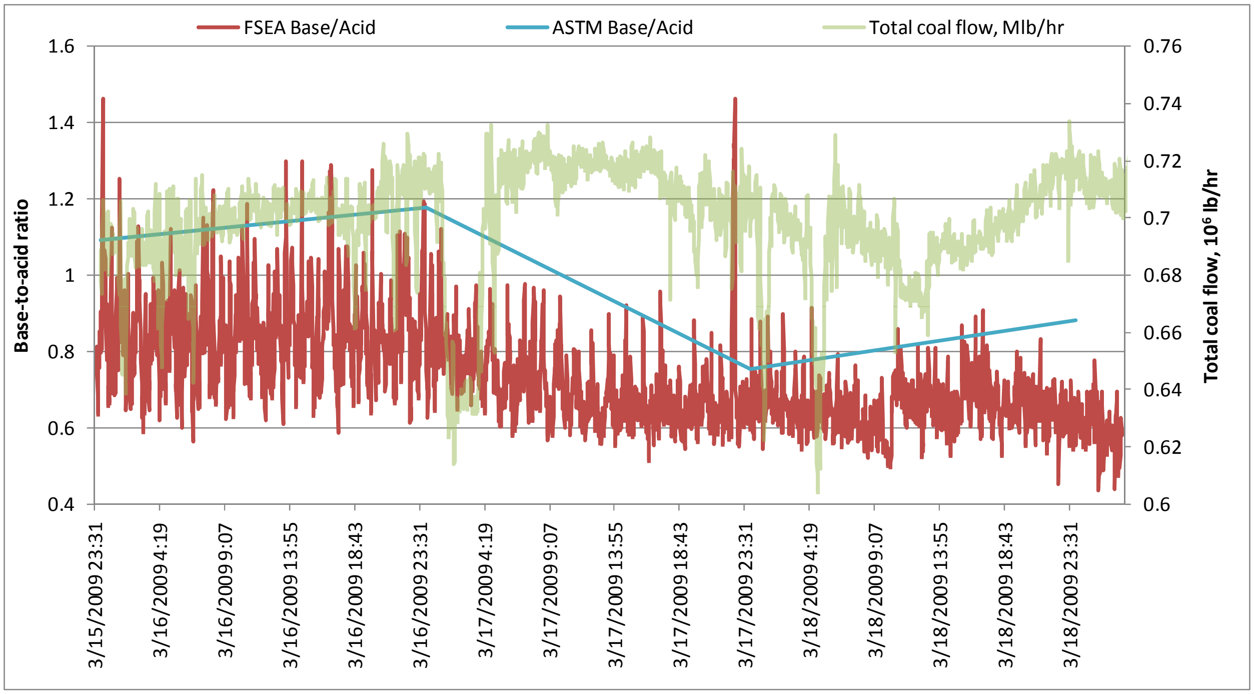

Figure 5. Coal belt flow and base-to-acid ratio (determined with FSEA and by ASTM ash composition analyses performed on composite coal samples) during the testing. The FSEA data was corrected for a 23-hour lag time between filling the hoppers and estimated fuel fed to the cyclones.

Particulate Mass and Number Distribution

Mass Distribution as Function of Location

The total mass loadings obtained with the multicyclone and impactors are illustrated in **Figure 6**. The results show a high average loading of $4.96\text{x}10^6$ micrograms per dry standard cubic meter (µg/dscm) at the ESP inlet, and average scrubber inlet and outlet loadings of $1.1\text{x}10^4$ µg/dscm and $1.08\text{x}10^4$ µg/dscm, respectively. Significant removal of particulate occurred across the ESP, with removal efficiency of 99.76%. These results show that very little removal of particulate material has occurred across the wet scrubber system. This is consistent with past work conducted by Markowski and others (1983) (a literature review is contained in **Appendix B** of this report). The results are also summarized in **Table 8**.

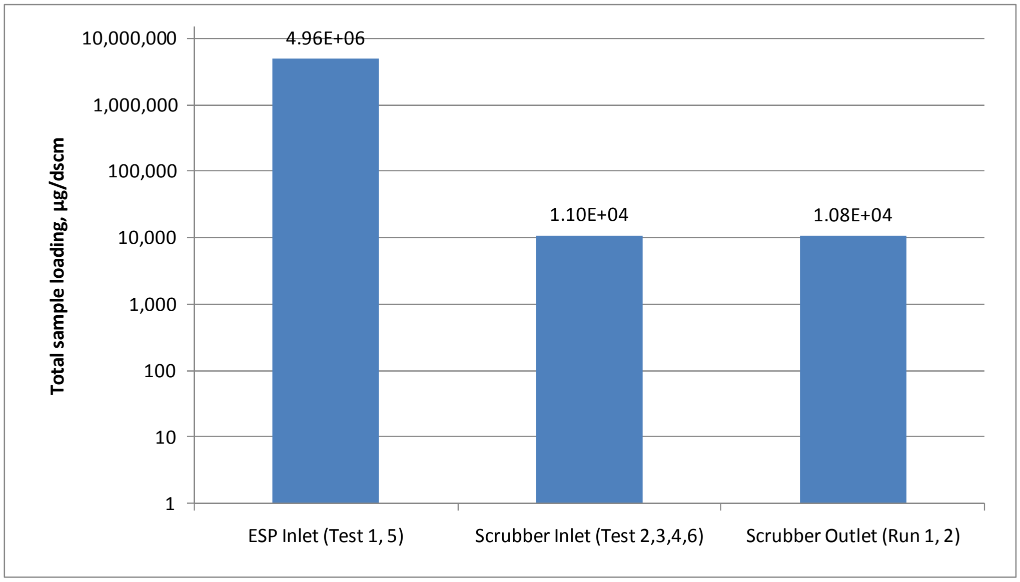

Figure 6. Total mass loadings at ESP inlet, wet scrubber inlet, and wet scrubber outlet.

Table 8. Total mass loadings for all testing conducted at ESP inlet, wet scrubber inlet, and wet scrubber outlet.

				Sampler loading		Total loading

Particulate Mass Loading as a Function of Size

Sampling at the ESP inlet was conducted using both the multicyclone and the impactor. The cyclones are designed to capture larger-size particles and the impactor collects small particles. **Figure 7** shows the mass size distributions for the cyclone and impactor. The size distribution of the particulate at the ESP inlet is multimodal. The larger particles are typically derived from mineral grains in the coal such as quartz, clays, and pyrite minerals. The intermediate-sized particles are typically derived from small minerals and organically associated elements. Particles less than a micron in diameter and finer are condensed vapor phase species.

The sample collected on 3/17/09 show a multimodal size distribution, with a mode occurring at one to three microns, and another mode at 0.1 µm. The sample collected on 3/19/09 also has a multimodal distribution, with a shift in the finer mode from 0.1 µm to about 0.5 µm. This shift may be due to the change in fuel composition (the coal sample collected on 3/17/09 had a higher base-to-acid ratio as compared to the coal collected on 3/19/09).

The mass size distribution of the particulate collected upstream of the scrubber is illustrated in **Figure 8**. Sampling was conducted at this location on all four days of the period. The results show a bimodal distribution of particles with a mode between one to two microns and another mode between seven and eleven microns. A general trend of decreasing abundance of the modes during the testing is observed. The change in abundance is likely due to changes in coal ash composition. Coals sampled on 3/16 and 3/17 had higher base-to-acid ratios; coals on 3/18 and 3/19 had lower ratios.

The mass size distribution of the scrubber outlet particulate is illustrated in **Figure 9**. The size distribution shows a main mode at about 0.8 µm and possibly a minor larger mode of 2 µm. The particle size distribution is shifted to finer particles downstream of the scrubber and the smaller particle size mode appears to dominate the size distribution. The samples were collected on 3/18 and 3/19, when the coals fired had lower base-to-acid ratios.

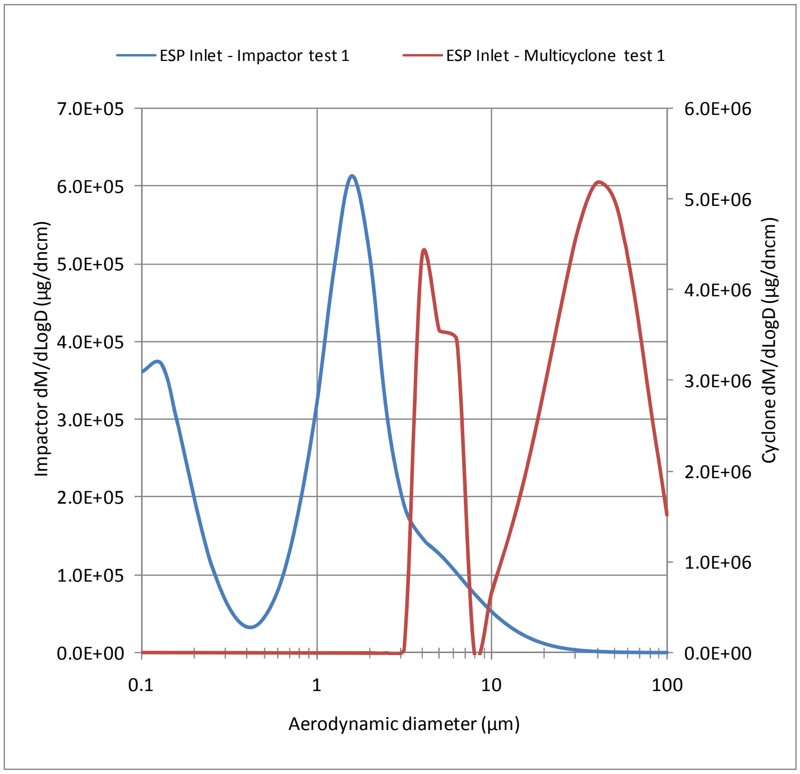

Figure 7a. Multicyclone and impactor data collected at ESP inlet on 3/17/09.

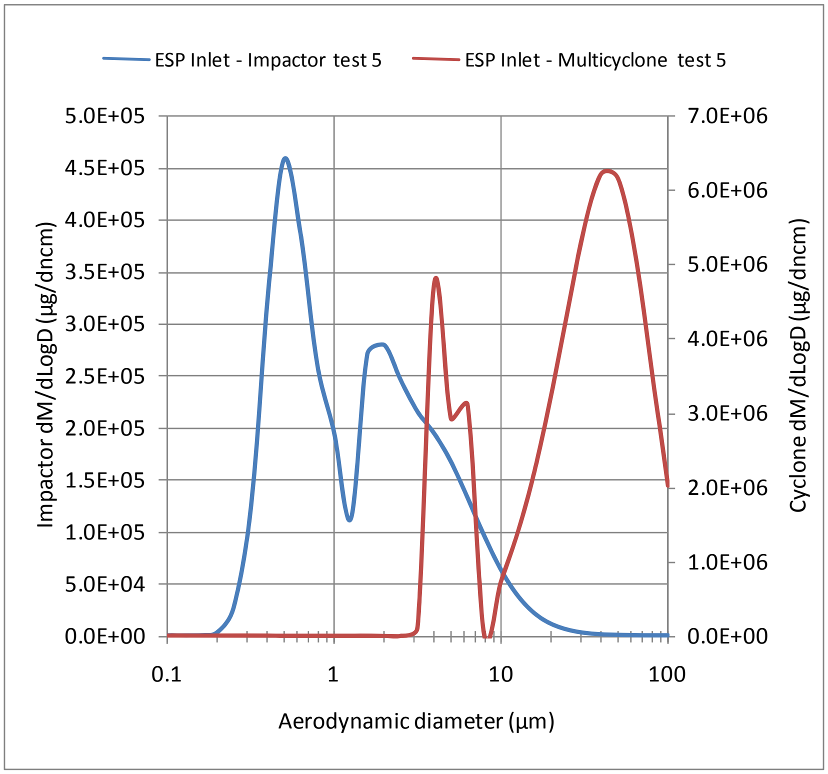

Figure 7b. Multicyclone and impactor data collected at ESP inlet on 3/19/09.

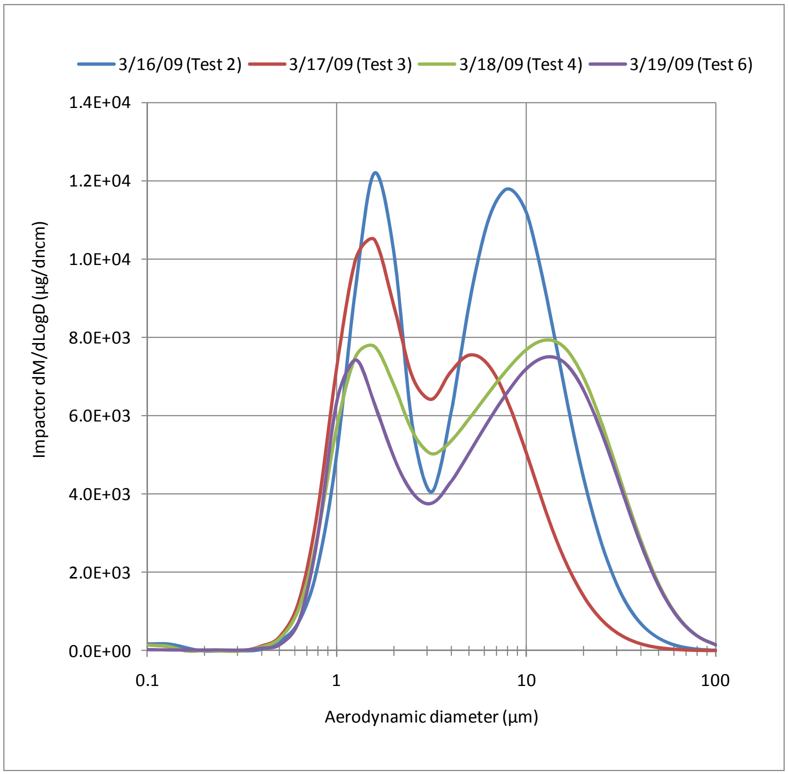

Figure 8. Mass versus size distribution of ash collected downstream of the ESP at the scrubber inlet.

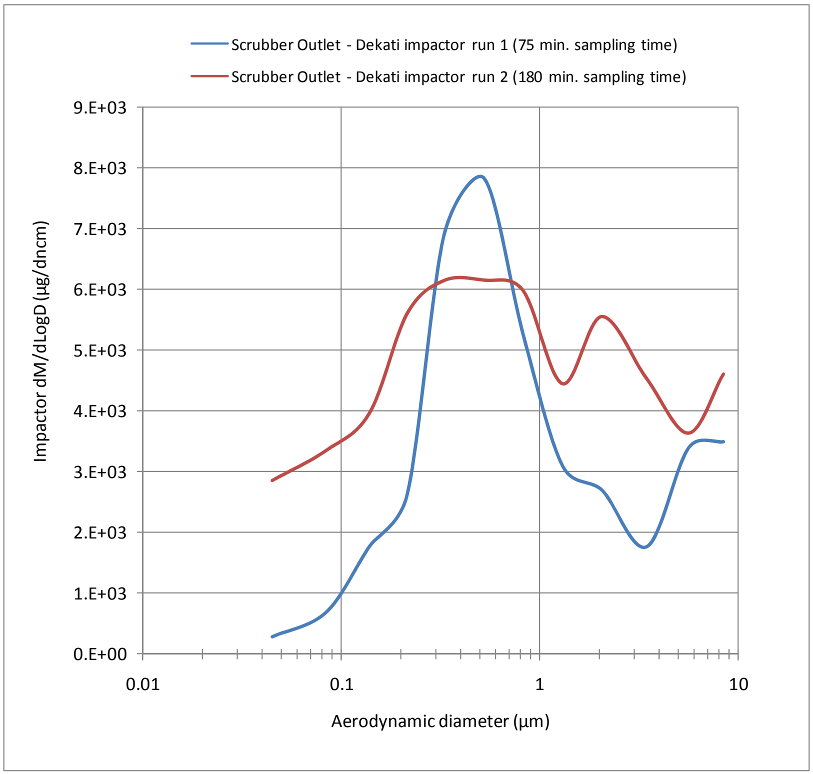

Figure 9. Mass distribution of particulate collected downstream of scrubber.

Particle Number Size Distribution

The number distributions for the particles are shown in **Figures 10** through **12** for the ESP inlet, scrubber inlet, and scrubber outlet. This information is shown as the number of particles per dry normal cubic centimeters (*not* cubic meters ash summarized above). This is the convention used by researchers.

The number of particle increases significantly with decreasing particles size. **Figure 10** shows the number of particles for the scrubber inlet. The ESP inlet sample had the highest number of particles in the smallest size fraction. The number of particles in the smallest size fraction at the scrubber inlet and outlet are similar – the slight increase in number at the scrubber outlet is likely to differences in sampling methods.

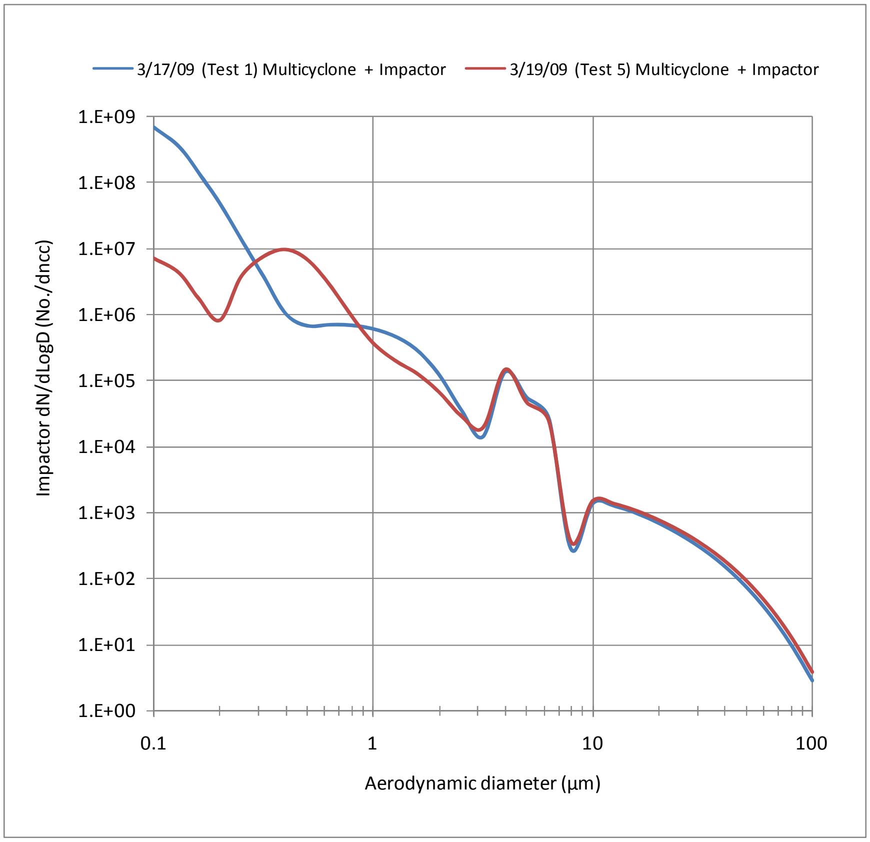

Figure 10. Number of particles as a function of size at the ESP Inlet.

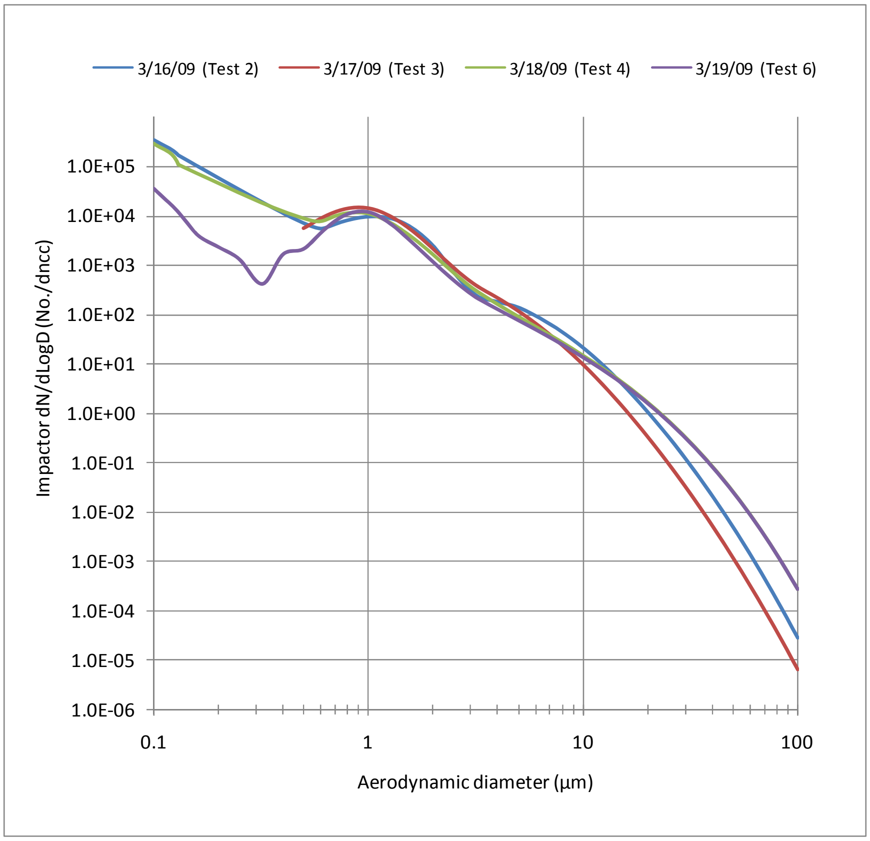

Figure 11. Number of particles as a function of size at the scrubber inlet.

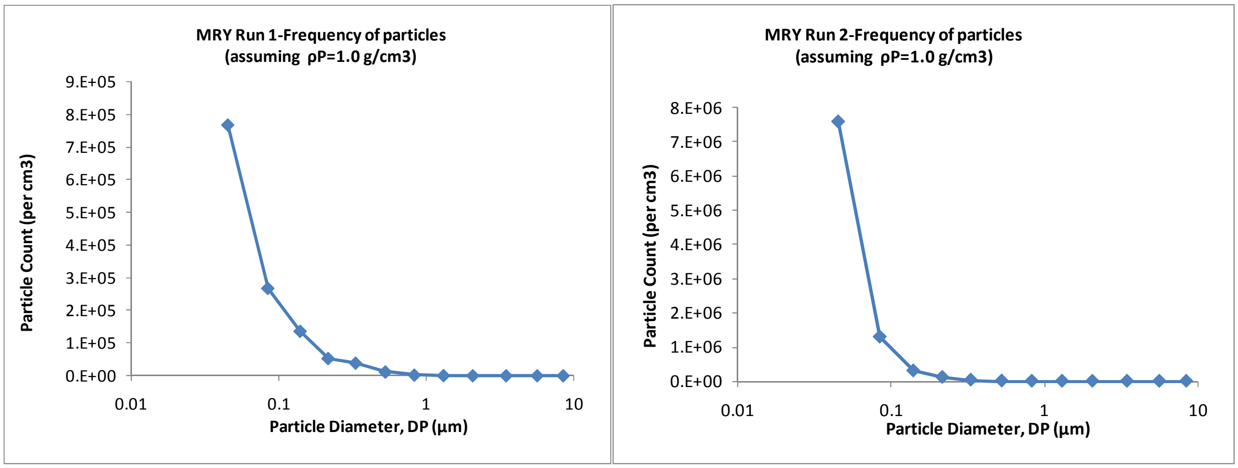

Figure 12. Number of particles as a function of size at the scrubber outlet.

Scanning Mobility Particle Scanning (SMPS)

Number-based concentration data obtained by the SMPS system at the scrubber outlet is shown in **Figures 13** and **14**. The data shown are for the on one good data set obtained during the sampling trip. A summary of the conditions at the sampling site that limited the ability of the SMPS to gain reliable data is listed in the Appendix.

The SMPS reports size data on a nanometer (nm) scale, not a micrometer (µm) scale. There are 1,000 nm in one micron. The data shown was obtained from a 10-sample test run, each 60 seconds apart, and includes two scans per sample: 60 seconds for the up scan and 30 seconds for the down scan. The scan window of the instrument covers a particle range of 16.5–605 nm (0.0165–0.605 µm).

Plots of the concentration versus particle diameter are given in **Figure 13** for number basis and in **Figure 14** for the mass basis. The number of particles observed using the SMPS is larger than that observed for the impactors but it is generally consistent the impactor data.

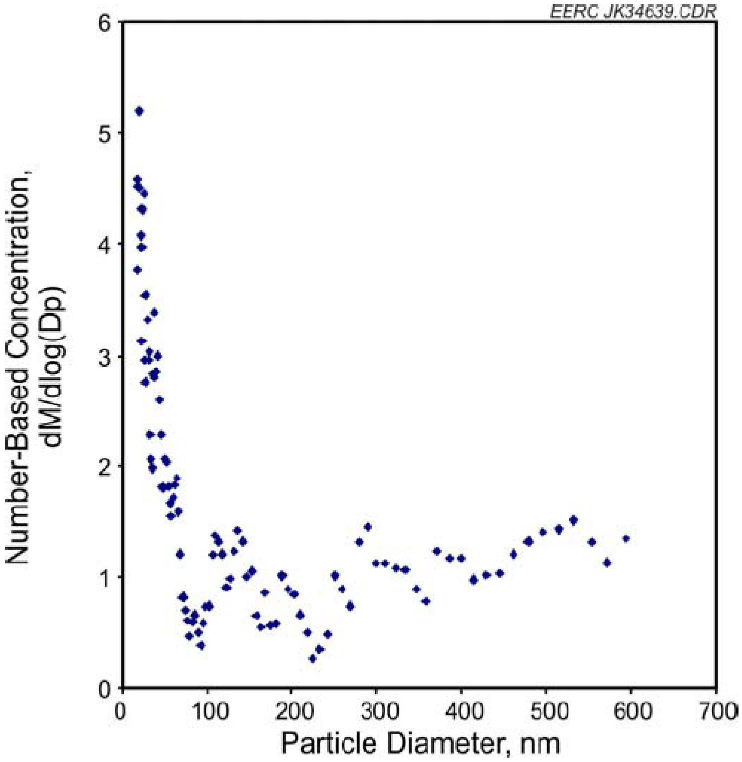

Figure 13. Plot of number-based particle concentration as a function of particle diameter (nanometers).

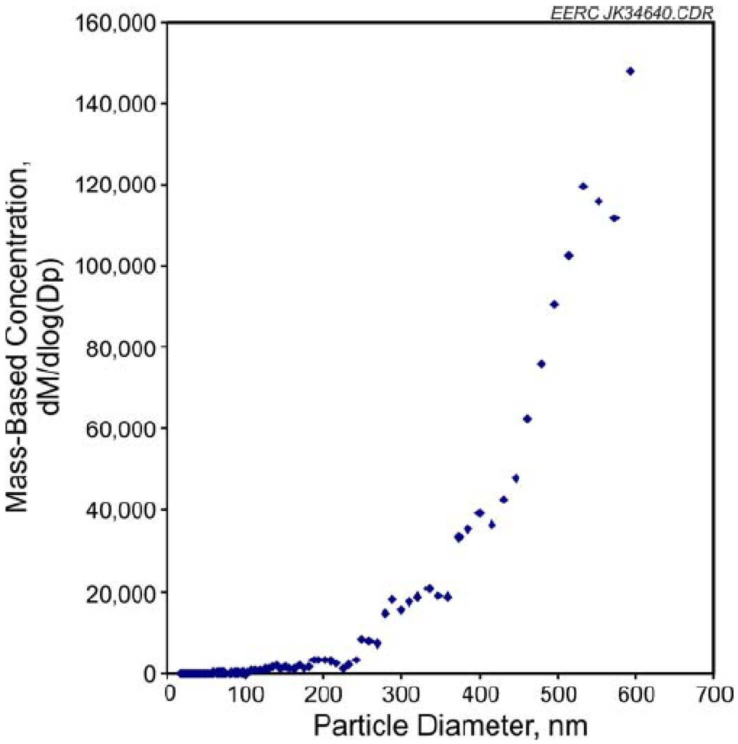

Figure 14. Plot of mass-based particle concentration as a function of particle diameter (nanometers).

Bulk Composition of Ash Materials

The composition of the size fractions of ash materials collected using the multicyclone are summarized for the element of interest specifically the Na, K, Ca, and S. These elements produce very small particles upon combustion. Data is available in the appendix that includes the major elements determined. The trends for the ESP inlet are shown in **Figure 15** for sodium, potassium, calcium and sulfur, and in **Figure 16** for silicon, aluminum, magnesium and iron. The results show concentrating of the elements in the particles that are less than 10 μm in diameter.

Figure 17 shows the trend for the ESP inlet cyclone samples (cyclones 1, 3 and 4) for sodium, potassium, calcium and sulfur and **Figure 18** shows the trends for silicon, aluminum, magnesium and iron for the ESP inlet cyclone samples.

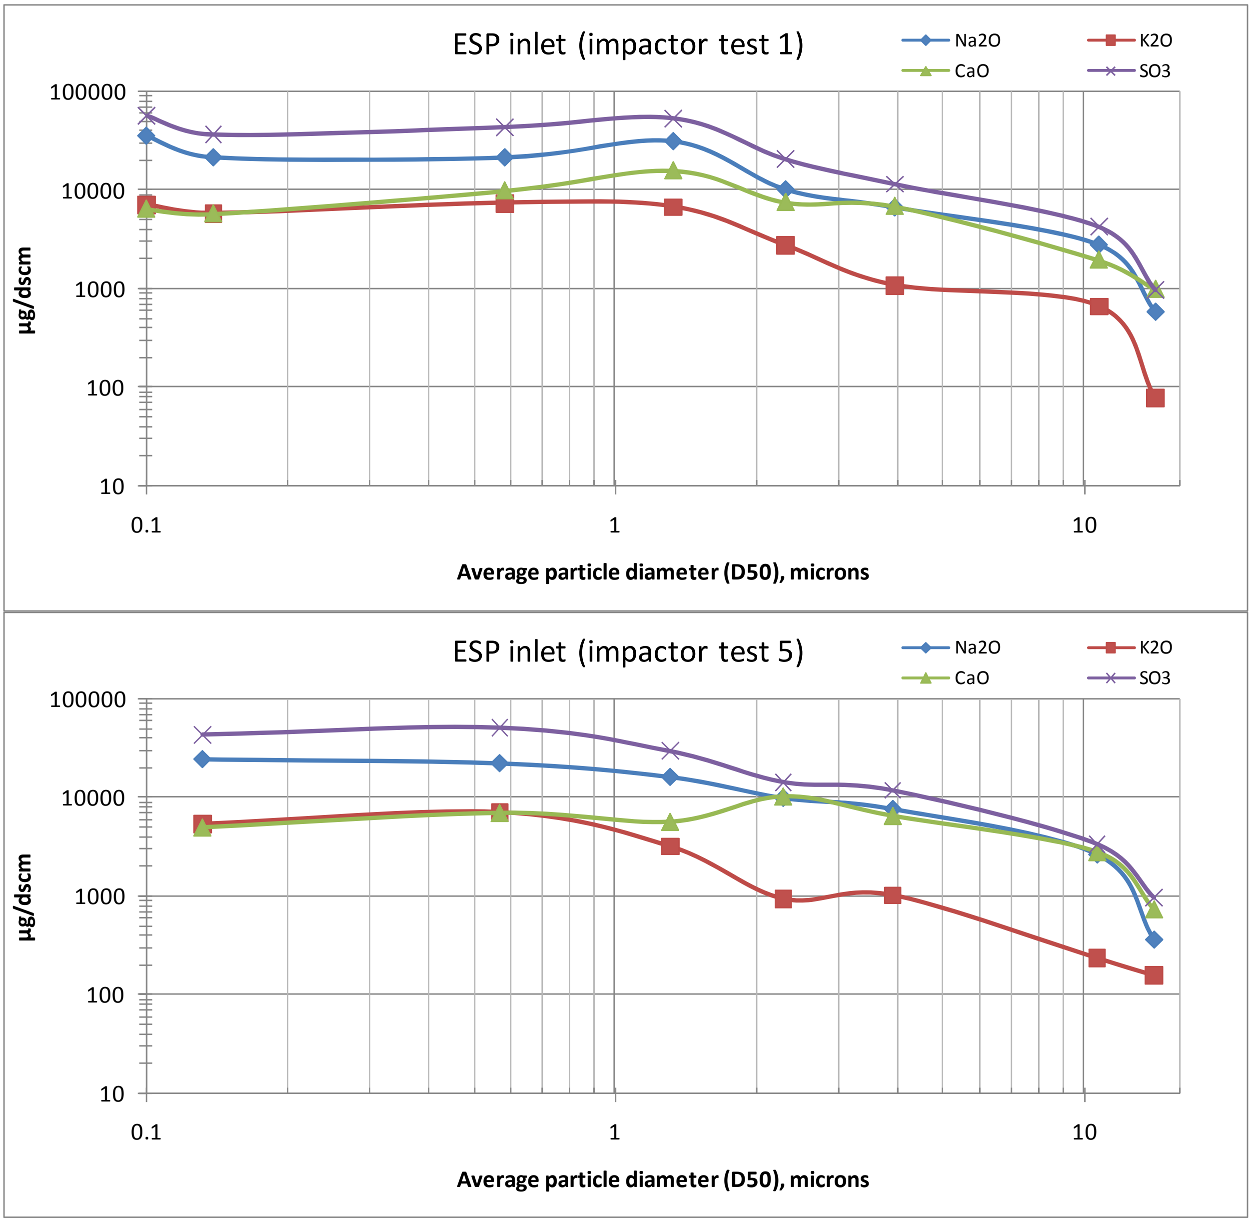

Figure 15. Sodium, potassium, calcium and sulfur concentrations as a function of average particle diameter for ESP inlet (impactor) samples.

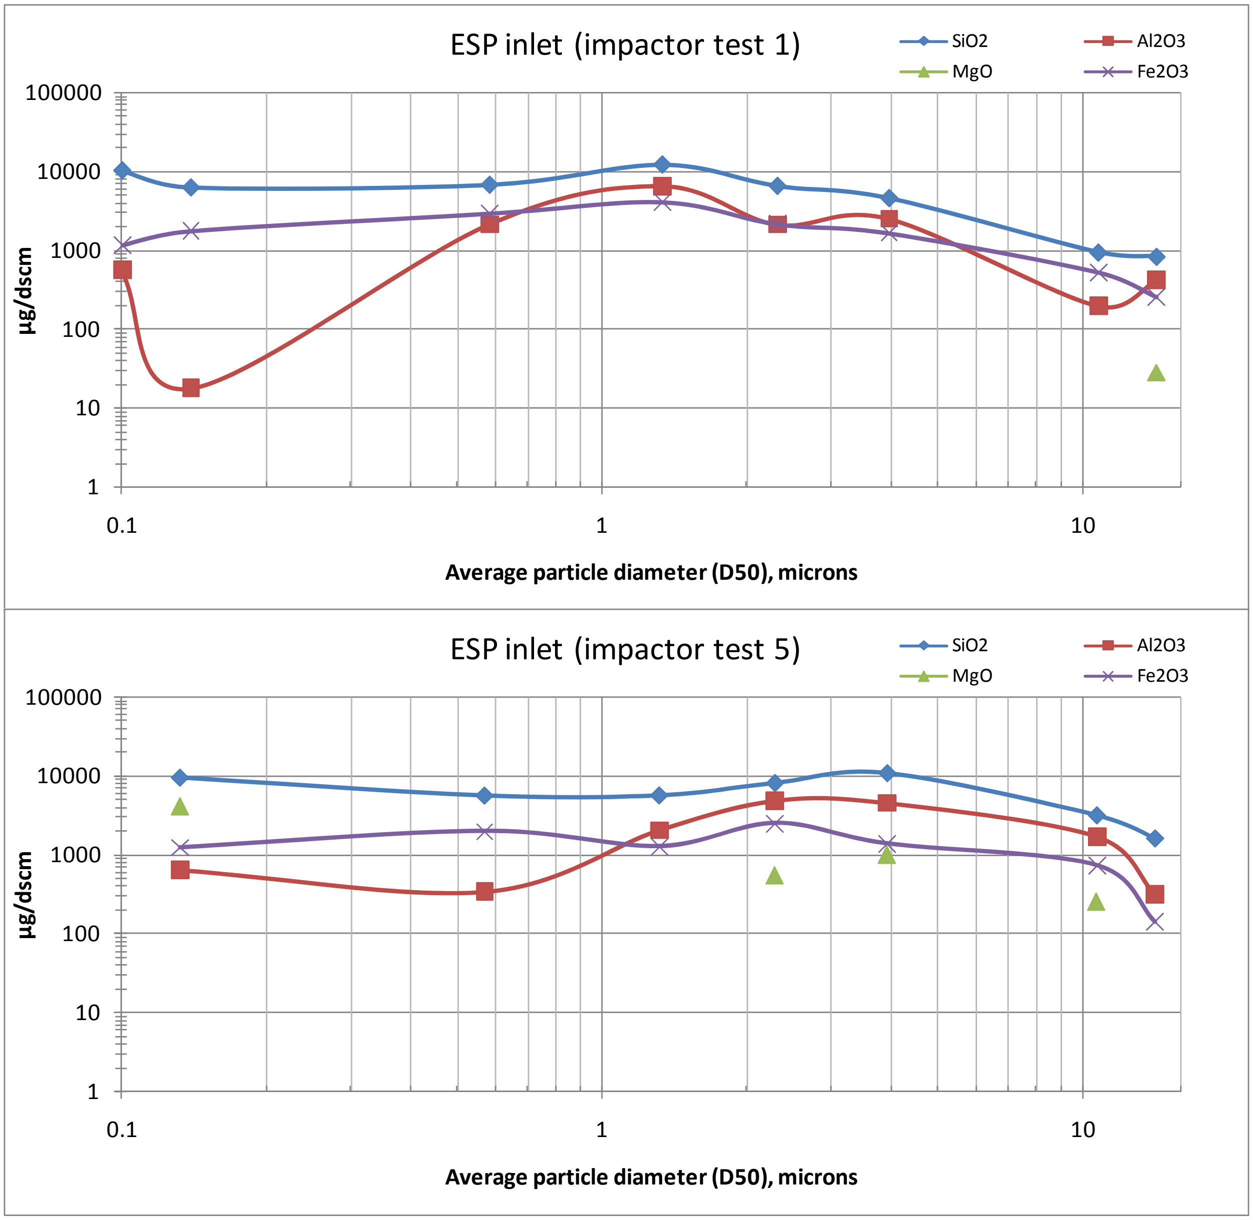

Figure 16. Silicon, aluminum, magnesium and iron concentrations as a function of average particle diameter for ESP inlet (impactor) samples.

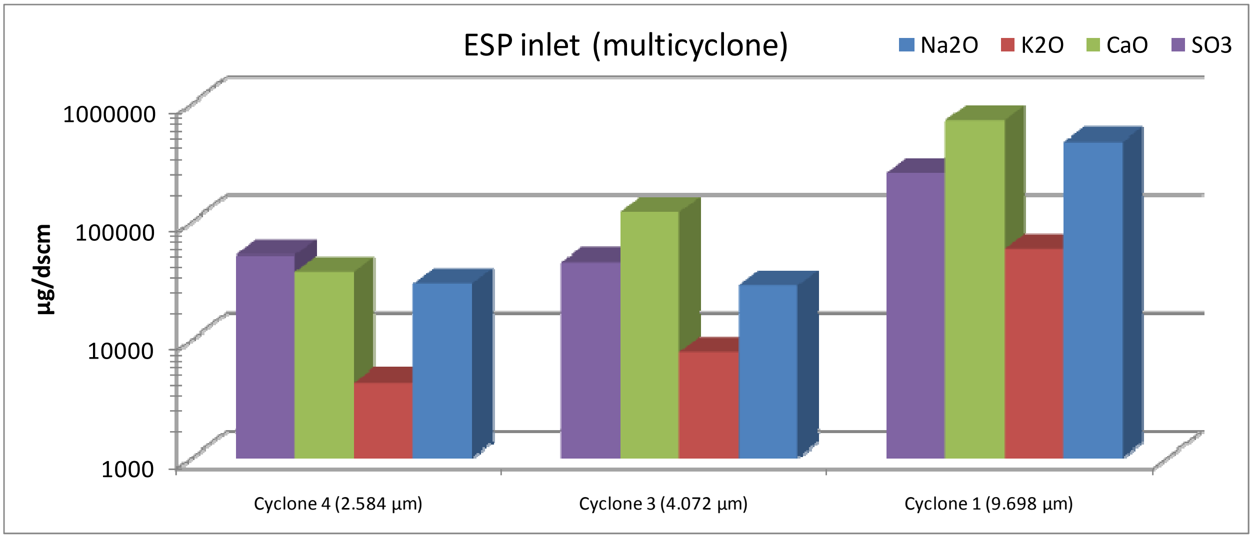

Figure 17. Sodium, potassium, calcium and sulfur concentrations for ESP inlet cyclone samples.

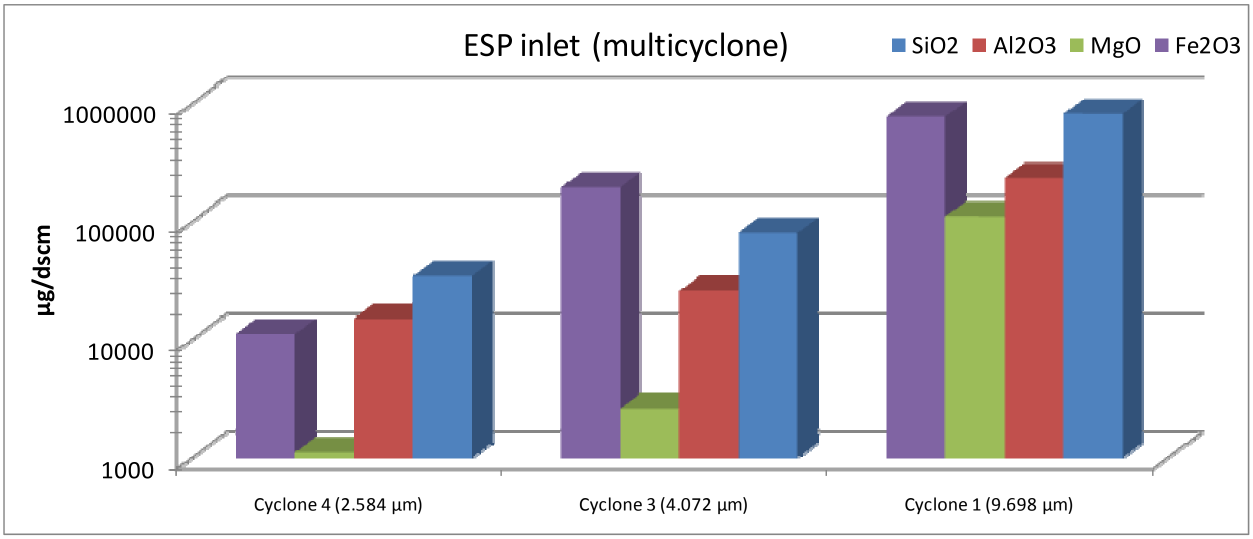

Figure 18. Silicon, aluminum, magnesium and iron concentrations for ESP inlet cyclone samples.

Analysis using digestion and inductively coupled plasma–mass spectrometry was performed to determine the concentrations of selected major elements (Ca, Fe, Mg, P, K, and Na) in the ash collected in the multicyclone stages. Table 9 lists the composition of selected elements based on the total sample collected in the multicyclone. Table 10 displays the fraction of each element, based on the total percent found in Table 9, by each cyclone stage. The largest concentrations of the selected elements were found in the first cyclone stage. The nozzle sample is material collected within the nozzle before the first multicyclone stage. This material is not size-fractionated.

The concentrations of the cyclone ash analyzed with ICP-MS cannot be compared well with the ash analyzed using SEM, as the ICP-MS samples were not analyzed for all major elements (including silicon, aluminum and sulfur).

Table 9. Percentage of each element in the total multicyclone sample (EERC).

Element	03/17/2009	03/19/2009
Calcium	13.36	12.15
Iron	6.85	6.54
Magnesium	3.27	3.14
Phosphorous	LBD*	LBD
Potassium	0.93	1.00
Sodium	6.63	6.26

*Level below detection (<400 ppm).

Table 10. Fractional percentage of each element by stage (EERC).

	03/17/2009				03/19/2009			
Element	Nozzle	Stage 1	Stage 3	Stage 4	Nozzle	Stage 1	Stage 3	Stage 4
Calcium	3.96	81.23	11.63	3.18	4.99	81.98	9.77	3.26
Iron	4.21	81.77	10.16	3.86	5.25	81.06	8.90	4.79
Magnesium	4.10	81.45	11.71	2.75	5.25	81.81	9.91	3.03
Phosphorous	LBD	LBD	LBD	LBD	LBD	LBD	LBD	LBD
Potassium	3.91	77.32	12.77	5.99	5.08	80.67	10.18	4.07
Sodium	4.21	77.80	12.82	5.17	5.67	80.59	9.88	3.85

The distribution of sodium, potassium, calcium and sulfur is illustrated in **Figure 19** and the distribution of silicon, aluminum, magnesium and iron is shown in **Figure 20**. The results show higher levels of sodium, potassium and sulfur at the one-micron level. The ESP was effective in removing larger-sized particles as well as some of the 0.1-µm particles. However, in the intermediate one-micron particle range the ESP is not as effective in removing the particles. This is a characteristic of all ESPs.

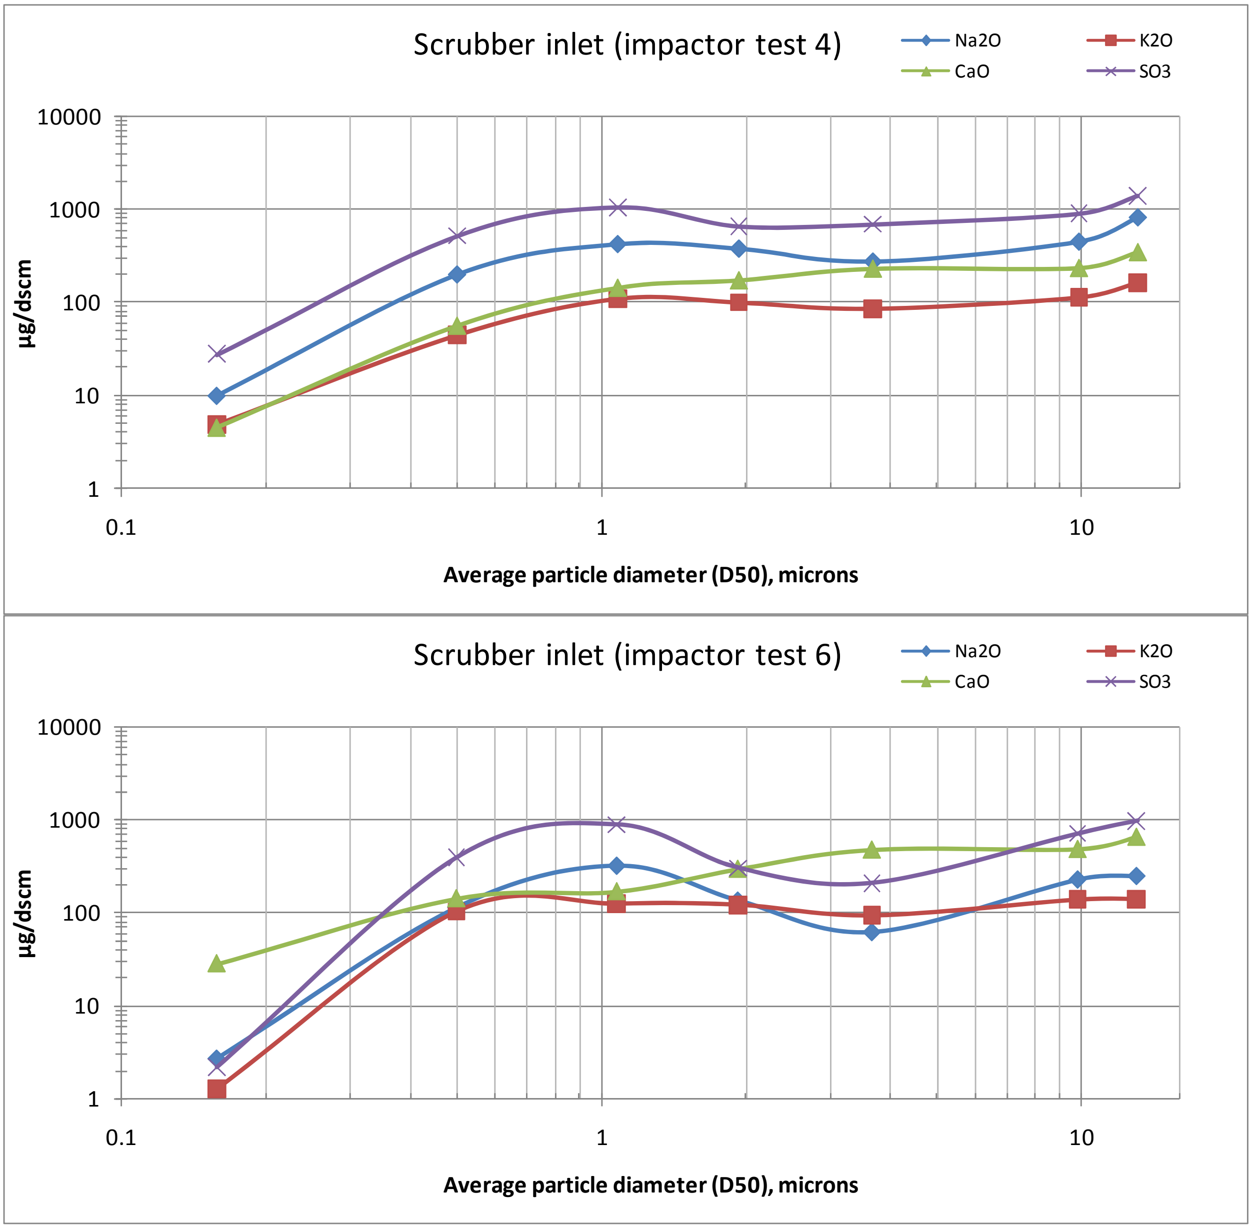

Figure 19. Sodium, potassium, calcium and sulfur concentrations as a function of average particle diameter in scrubber inlet samples.

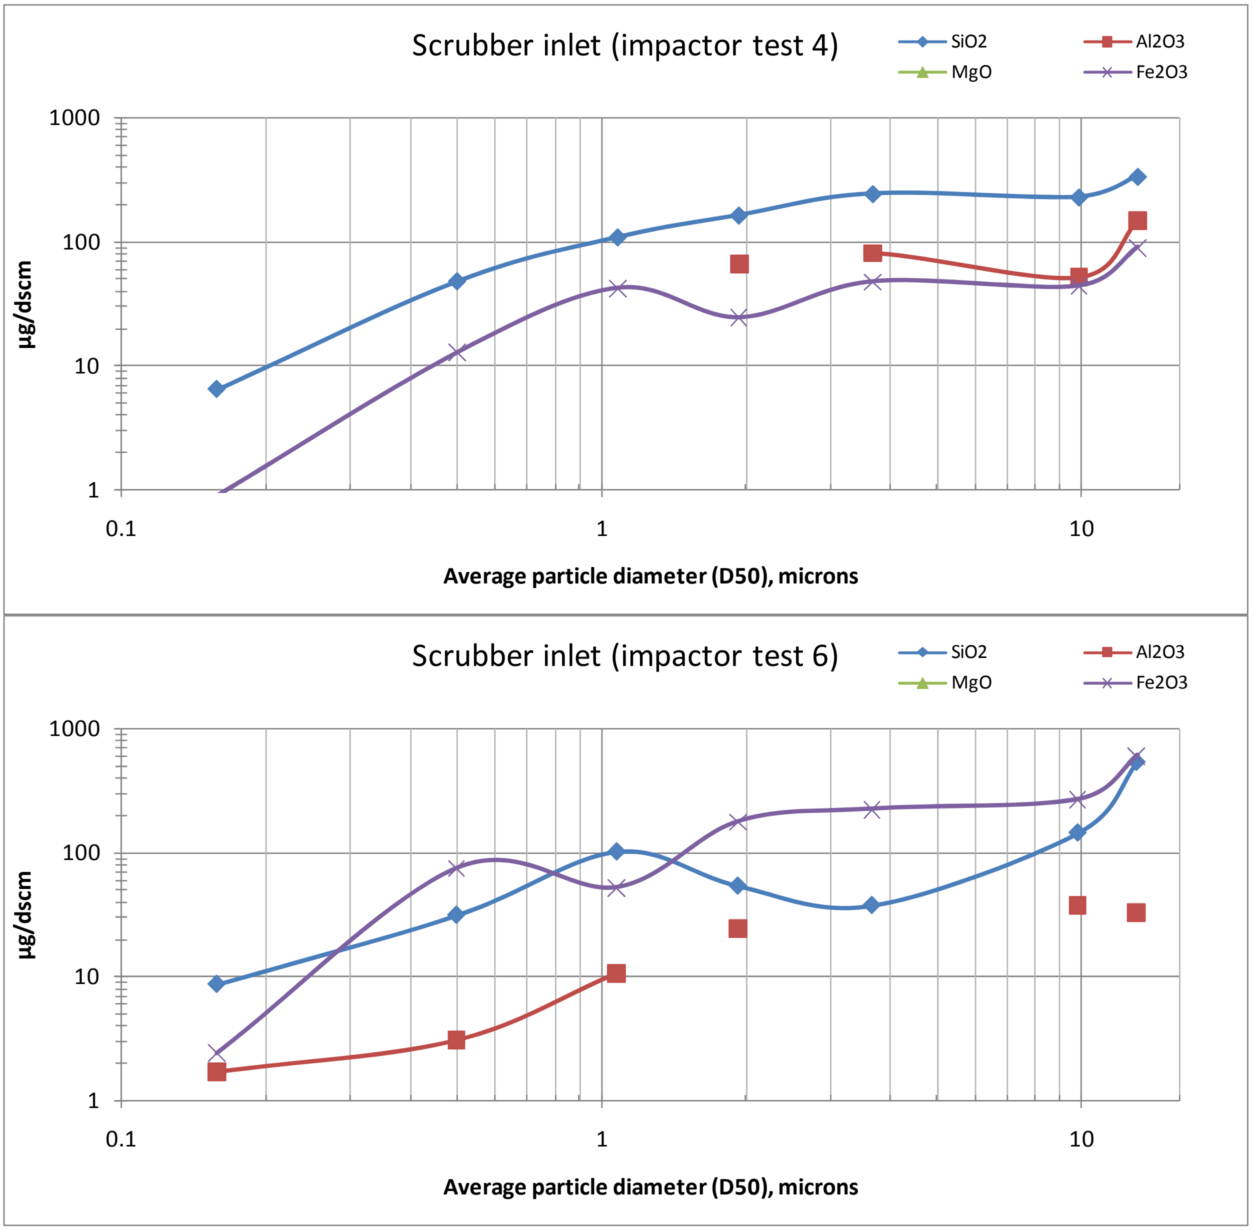

Figure 20. Silicon, aluminum, magnesium and iron concentrations as a function of average particle diameter in scrubber inlet samples.

The composition size distribution determined for sodium, potassium, calcium and sulfur downstream of the scrubber is illustrated in Figure 21. The results show a significant level of sodium and sulfur in the less than 1 µm size fraction. The DLPI sampling system provides very accurate sizing data in the submicron size range. The results show a maximum for sodium and sulfur at about 0.3 µm.

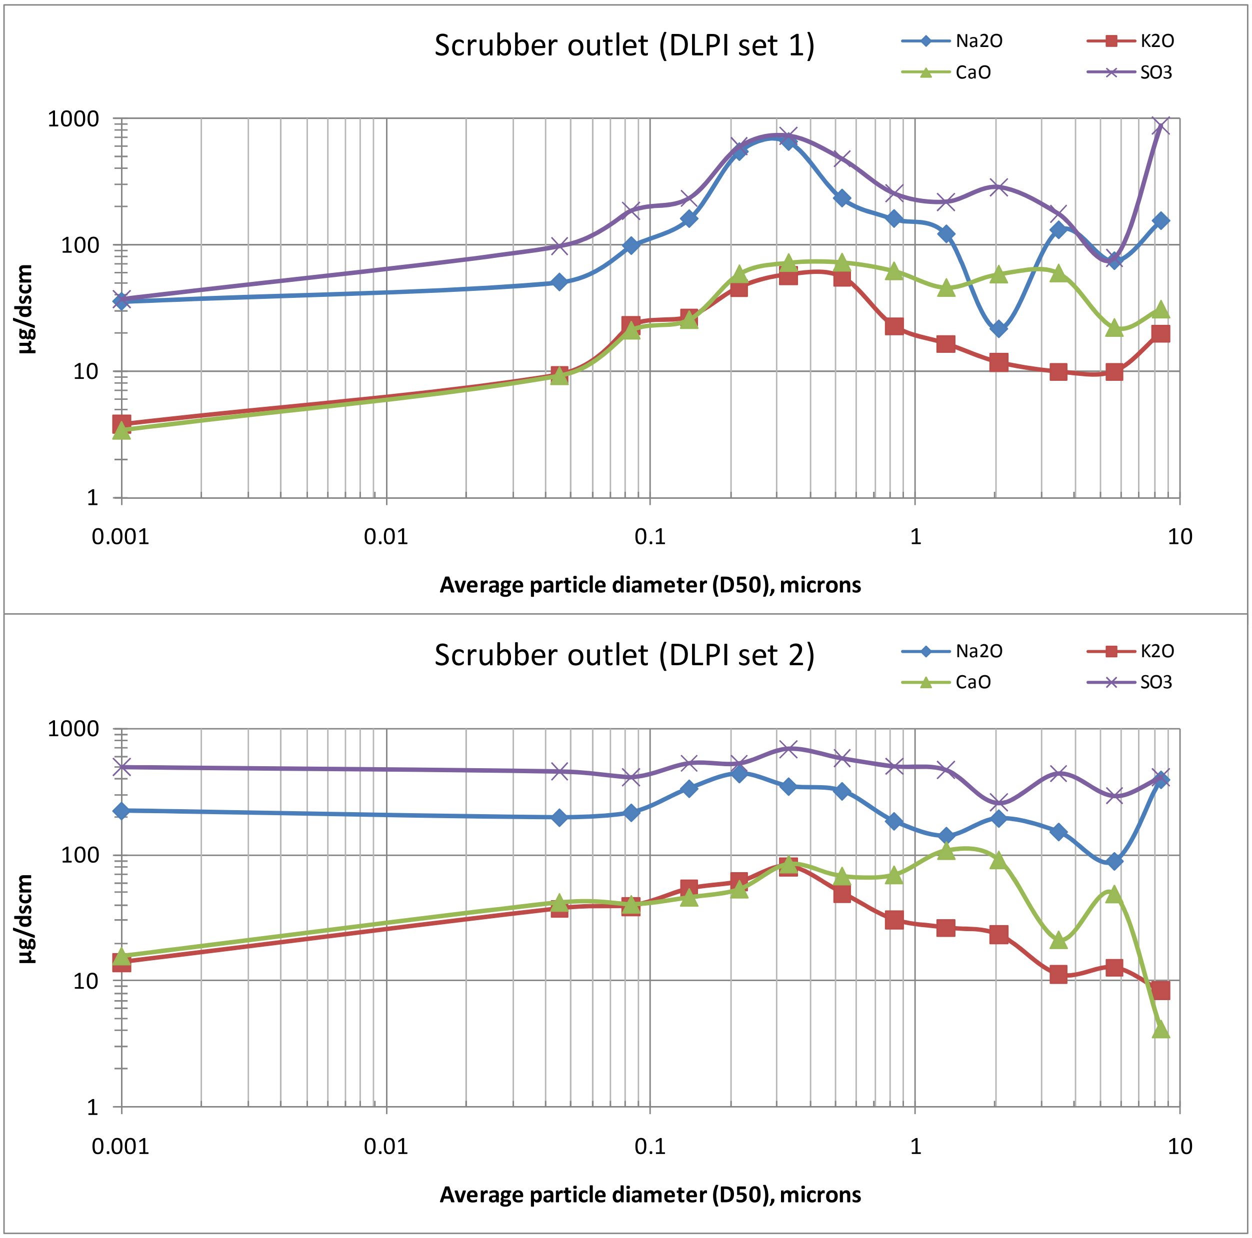

Figure 21. Sodium, potassium, calcium and sulfur concentrations as a function of average particle diameter in scrubber outlet samples.

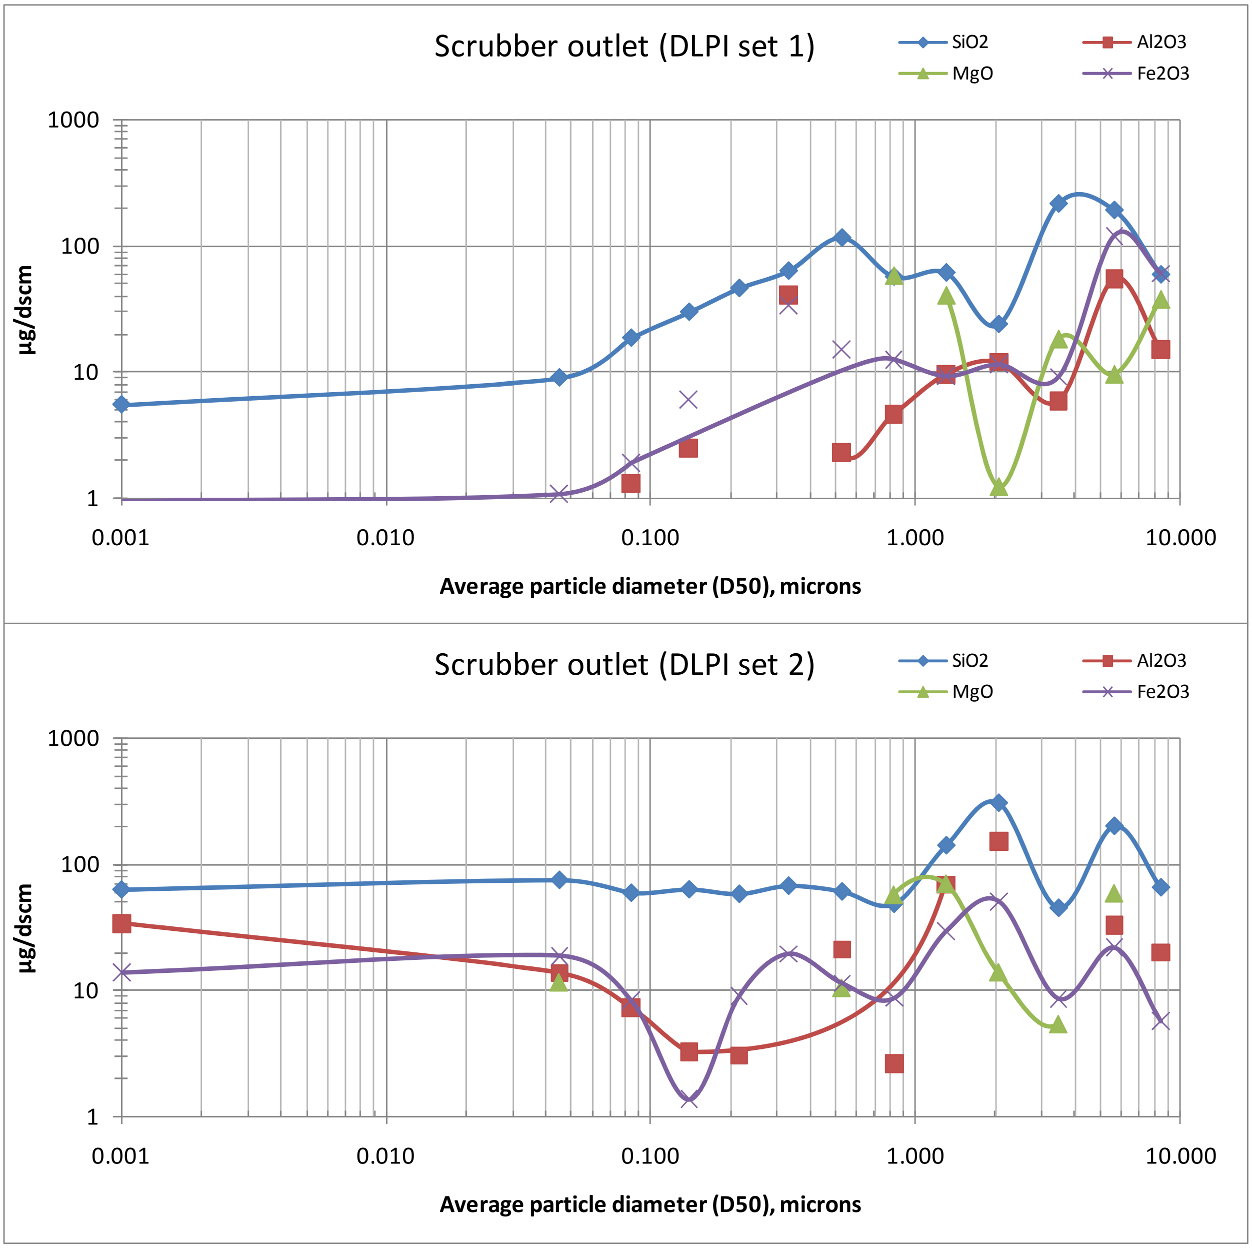

Figure 22. Silicon, aluminum, magnesium and iron concentrations as a function of average particle diameter in scrubber outlet samples.

Comparison of the mass of the particles in terms of composition is shown in **Figure 23**. The results show that sodium and potassium are reduced across the ESP. However, no reduction of sodium and potassium was observed across the scrubber. This is consistent with other scrubbers operating globally.

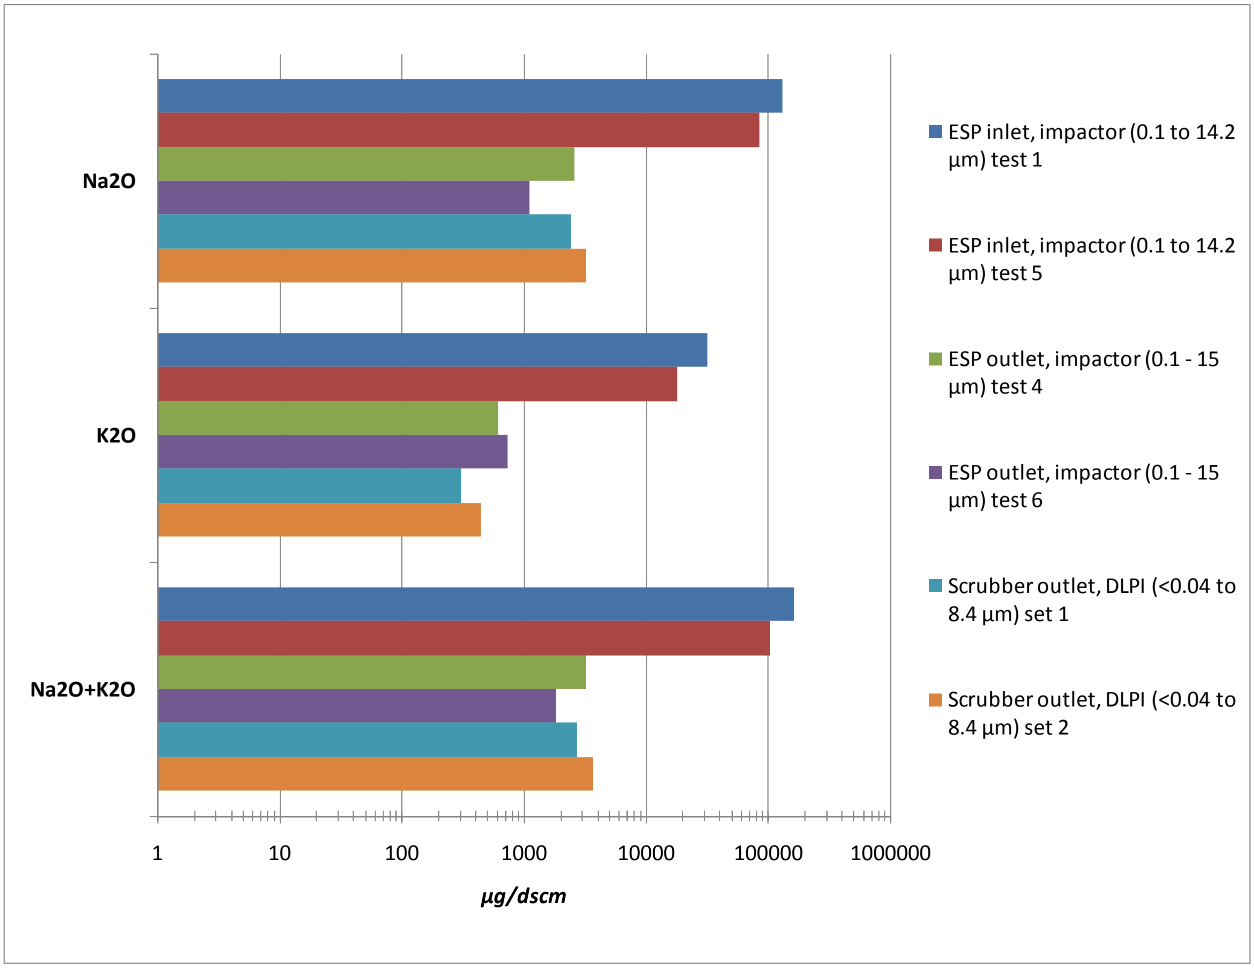

Figure 23. Mass of sodium and potassium oxide in the flue gas upstream and downstream of air pollution control devices at MRY.

SUMMARY AND CONCLUSIONS

Particulate sampling was conducted at Minnkota Power Cooperative's Milton R. Young plant to determine the particulate size and composition distribution of samples collected upstream of the ESP, upstream of the wet scrubber, and downstream of the wet scrubber. Emphasis was placed on determining the fate of sodium, potassium, and calcium since these elements can cause significant plugging and deposition problem.

During the testing, operating conditions of the plant were constant and there was no gas bypass. The coal fired during the testing remained relatively consistent. The as-received ash content ranged from 7.73 to 7.89%. Sodium oxide content of the ash ranged from 7.22 to 7.57% and the base-to-acid ratio decreased the last two days of testing (a result of a decrease in CaO content and an increase in SiO_2 and Al_2O_3 levels). Sampling upstream of the ESP and scrubber were conducted using a combination multicylones and impactors. The cyclones collected sized fractions of larger particles (greater than one to five microns) and the impactor collected the sub-micron particulate. Sampling downstream of the scrubber was conducted with a single cyclone followed by a 13-stage advanced impactor. In addition, the submicron particle number concentration was measured using a scanning mobility particle sizer (SMPS).

The results of the particulate mass information indicated a high loading at the ESP inlet of 4.96×10^6 µg/dscm, a scrubber inlet loading of 1.1×10^4 µg/dscm, and a scrubber outlet loading of 1.08×10^4 µg/dscm. These results show very little overall removal of the submicron particulate across the wet scrubber system. A significant fraction of the particulate was removed by the ESP, with a removal efficiency of 99.76%.

The size distribution of the particulate collected upstream of the ESP and upstream of the scrubber was multi-modal as summarized below:

- Upstream of the ESP there were at least three modes – a larger mode at 40 to 50 µm, a second mode at just under 10 µm, and third mode at about 1 µm. The larger particles are typically derived from mineral grains in the coal such as quartz, clays, and pyrite. The intermediate-sized particles are typically derived from small minerals and organically associated elements. The smaller mode (about one-micron and smaller) contains fine particles and condensed vapor phase species.
- Upstream of the scrubber there were two distinct modes – a larger mode between 8 to 10 µm and another mode centered at about 1 to 2 µm in diameter. The smaller mode is typically condensed vapor phase and small particles.
- Downstream of the scrubber, the primary mode centered at about 0.5 to 0.7 µm, and another possible mode occurred at 3 µm and larger.
- Particle number distributions were as follows:
    - Inlet to the ESP – between 1×10^7 to 10^8 particles per dry normal cubic centimeter (dncc);
    - Inlet to the scrubber is 10^5 particles/dncc;
    - Outlet of the scrubber 7×10^5 particles/dncc.
- Particle number distributions into the nanometer scale (1 µm = 1000 nm) was found to be as high as 10^5 particles/dncc.

Particle composition distributions of the particulate were determined for each of the major elements. The results were reported as µg/dscm of the element as illustrated in the Appendix and in the figures in the text.

- Upstream of the ESP the composition trends for sodium, potassium, calcium and sulfur showed greater concentrations of these elements in the particles that are smaller than 10 µm, with a significant increase in concentration in the flue gas at a particle size of less than 2 µm. There is another increase at 0.1 µm.
- Upstream of the scrubber the compositional trends for sodium, potassium, calcium and sulfur show higher levels at the 1 µm level. The ESP was effective in removing larger-sized particles, as well as some of the 0.1 µm particles. However, in the intermediate 1 µm particles, the ESP is not as effective in removing the particles.
- Downstream of the scrubber the composition size distribution determined for sodium, potassium, calcium and sulfur showed significant levels of sodium and sulfur in size fraction finer than 1 µm. The DLPI sampling system provides very accurate sizing data in the submicron size range. Other elements such as aluminum, silicon and iron show a significant depletion below 1 µm.

Comparison of the characteristics of the particles in terms of mass and composition indicate that, at the time of the testing, the total average mass of the particulate was about 10,800 µg/dscm. The particulate consisted mainly of sodium, potassium, and sulfur. The total quantity of sodium and potassium exiting was between 2000 to 3000 µg/dscm.

APPENDIX B - SMPS FIELD CONDITIONS AND CHALLENGES

Temperature

The temperature in the field during this test was approximately 24°F. This made it very difficult for the equipment to start and warm up to normal operation conditions, especially the CPC. With the help of a fish tent, carpets, and small blow heaters, the CPC was brought to normal operating temperature. Because of the cold conditions, there was a significant condensation issue in the lines that fed the SMPS system. Although this problem was reasonably resolved for all lines from the probe end to the EC by applying heat/thermal tapes, the lines connecting the EC and CPC also had a buildup of condensed fluid to the extent that they had to be drained at one point to help stabilize the flow via the CPC pump.

Wind

Another challenge faced in the field was the high winds of more than 20 mph. With the scrubber outlet location being about 105 feet above the ground, such windy conditions constantly shook the grid and the equipment; thereby introducing turbulence to the flow through the CPC pump.

Pore Flue Gas Pressure

A more serious problem was the lack of adequate positive pressure from the sampling port to supply enough flue gas through lines into the SMPS system. This resulted in very low counts observed in many data sets. Although the sampling port at the scrubber outlet is at positive pressure, it probably was not high enough to feed enough flue gas through the small nozzle of the sampling probe to the SMPS system.

Milton R. Young Unit 2

MRY Unit 2 is a Babcock & Wilcox (B&W) Carolina-type radiant boiler designed to burn high-moisture, high-slagging/fouling North Dakota lignite. Nominally rated at 3,050,000 lb/hr, this unit is a cyclone-fired, balanced-draft, pump-assisted circulation boiler. The unit began commercial operation in May 1977 and is base-loaded at 470 MW gross. The unit is equipped with a cold-side ESP for particulate control and a wet FGD unit for SO_2 control. The cold-side ESP has a specific collection area (SCA) of 375 ft^2/1000 acfm. The wet FGD for SO_2 control utilizes alkaline ash and lime. The MRY Station fires North Dakota lignite coal from the Kinneman Creek and Hagel Seams at the Center Mine.

Form of Sodium in Center Lignite

Sodium is associated with the organic matrix in Center lignite. That means the sodium is atomically dispersed in the organic matrix. The sodium is associated with a carboxylic acid groups (ion exchange sites). The carboxylic acid groups act as bonding sites for various elements such as Ba, Ca, Mg, and Sr along with minor amounts of K. Figure C-1 illustrates the bonding of sodium to the organic fraction of the coal and the association of other coal impurities.

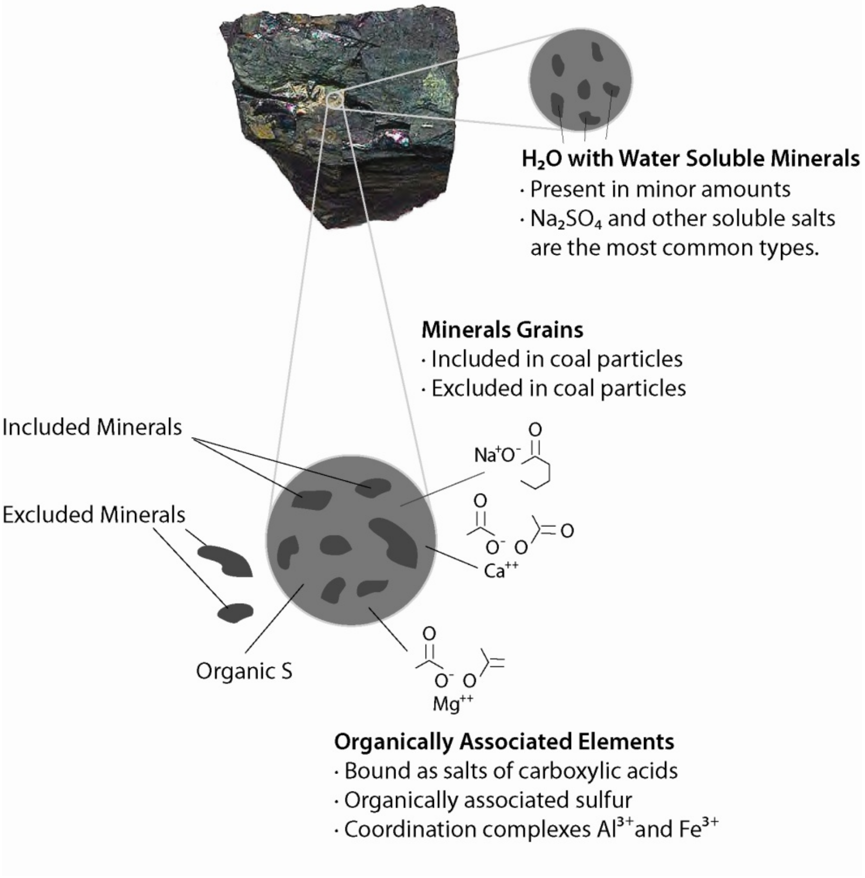

Figure C-1. Form of sodium in coal (Benson and Laumb, 2008).

Vaporization of sodium in PC and cyclone-fired systems

Sodium is a volatile element and will be transformed into a gas upon combustion. The vaporization of sodium during the combustion of lignite is a very well known fact that has been examined by numerous investigators; include work conducted by MIT, CalTech, Sandia National Laboratory, National Energy Technology Laboratory, University of Utah, and others. For example, research conducted by Senior and others (2000) reported that relative to other coals, North Dakota lignite produced more vaporized ash. The actual amount vaporized for ND lignite is double the level vaporized as compared to subbituminous and lignite coals from Montana as illustrated in Figure C-2. Work conducted at the MRY plant related to the vaporization of sodium from a cyclone fired systems is illustrated in Figure C-3. The results show over two thirds of the sodium is not retained in the slag and is vaporized.

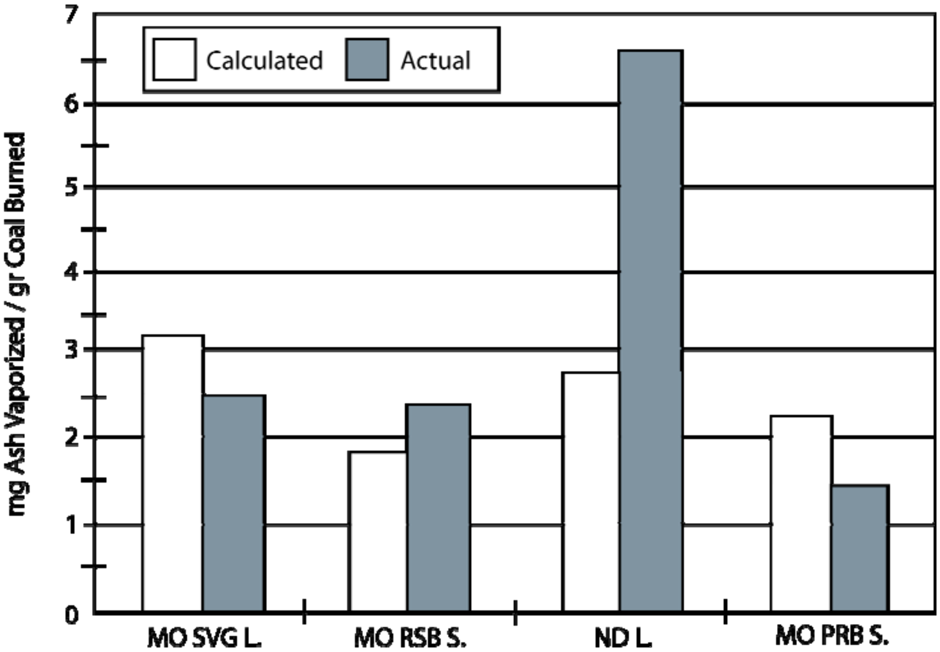

Figure C-2. Ash vaporized during combustion of lignite and subbituminous coals (Senior and others, 2000).

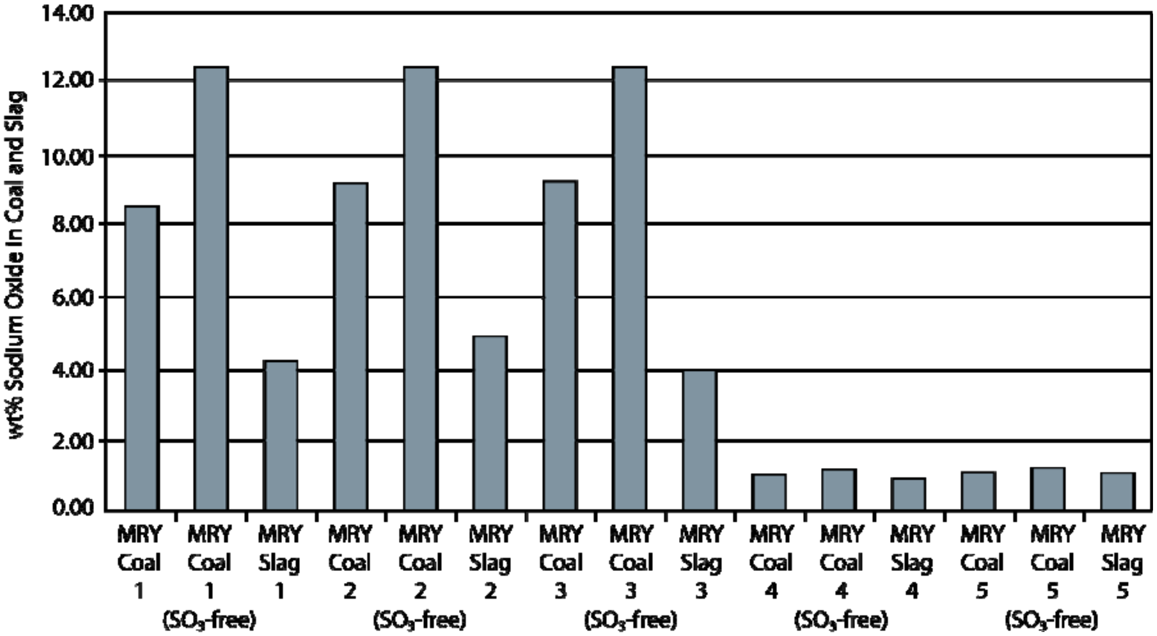

Figure C-3. Comparison of sodium levels in Center lignite coal and slag samples.

Condensation of vaporized species to form aerosols

EPA has evaluated the literature on particle formation during combustion and from other sources and incorporated it into an educational module that can be found on the following website (http://www.epa.gov/apti/bces/module3/formation/formate.htm). The classification of particle types shown by EPA is illustrated in Figure C-4. The EPA classification is consistent with the review conducted by Lighty and others (2000). Vaporized species can condense heterogeneously on surface of other entrained coarse ash particle and can condense homogeneously to form the fine and ultrafine particles. The distribution of particles depicted in Figure C-4 is shown on a frequency percent of particles by mass basis. The particle number versus size is also important and a comparison of the number of particles and particle size is summarized in Table C-1. The number of aerosol particles is significant. These particles have high surface areas and are very reactive.

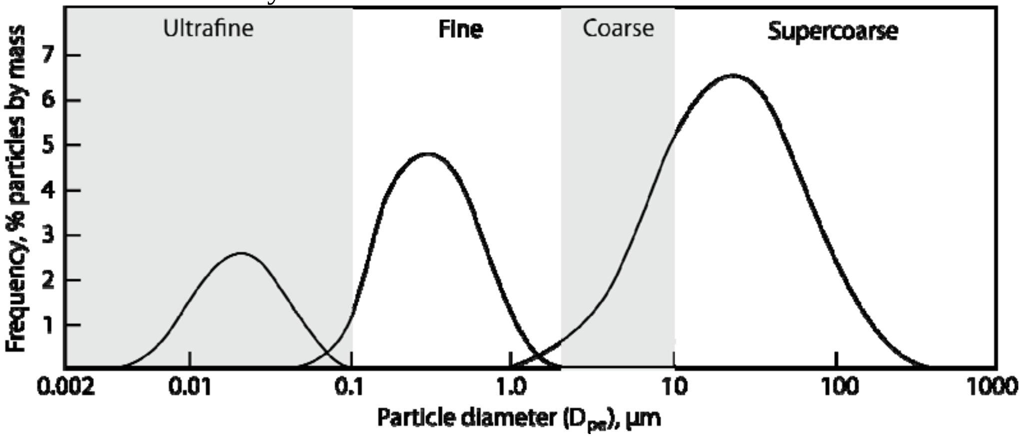

Figure C-4. Particle size categories used to classify particles (http://www.epa.gov/apti/bces/module3/category/category.htm)

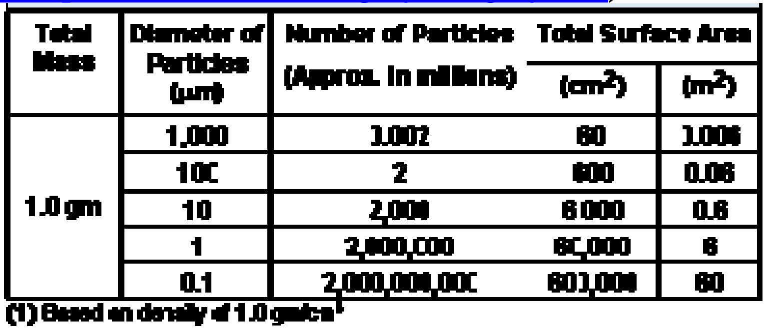
Table C-1. Particle size, number of particles, and surface area[1] **(http://www.epa.gov/apti/bces/module3/category/category.htm)**



Total Mass	Diameter of Particles (µm)	Number of Particles (Approx. In millions)	Total Surface Area (cm²)	(m²)
1.0 gm	1,000	0.002	60	0.006
	100	2	600	0.06
	10	2,000	6 000	0.6
	1	2,000,000	60,000	6
	0.1	2,000,000,000	600,000	60

(1) Based on density of 1.0 gm/cm³

Figure C-5 provides a comparison of the mass distribution and particle number distribution. As the particle size decreases the number of particles in the size fraction increases. In addition, as illustrated in Table C-1, the surface area increases significantly with decreasing particle resulting in the opportunity for reactive gases such as sulfur oxides to react forming sticky phases that bond particles together.

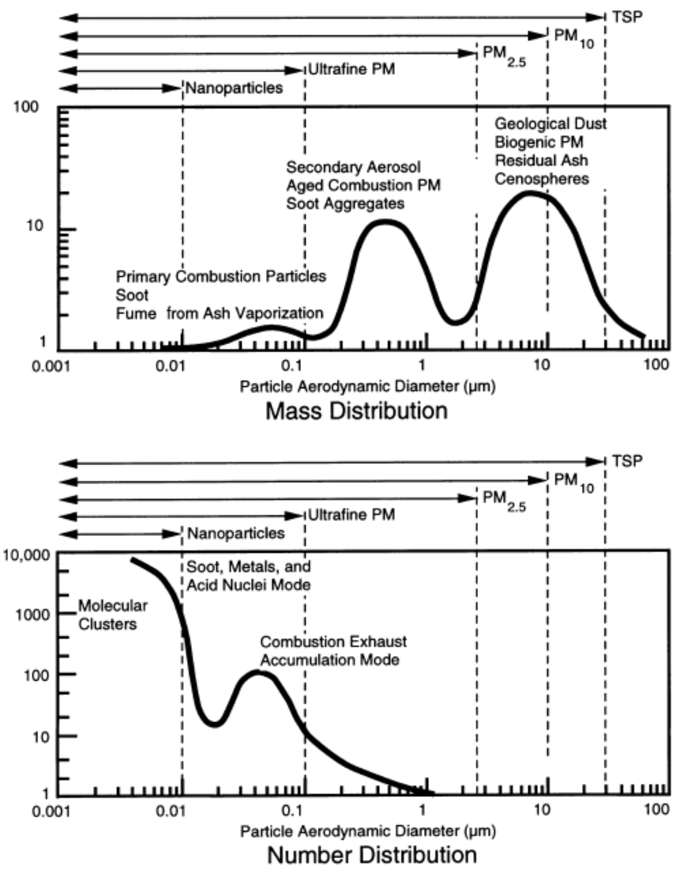


Figure C-5. Comparison of mass distribution and particle number distribution for combustion derived particles and aerosols (Lighty and others, 2000).

Particle size distributions for fly ash collected upstream and downstream of an ESP are illustrated in Figure C-6. This work was conducted by Markowski and others (2000) specifically aimed at characterizing the submicron aerosol mode of fly ash formation.

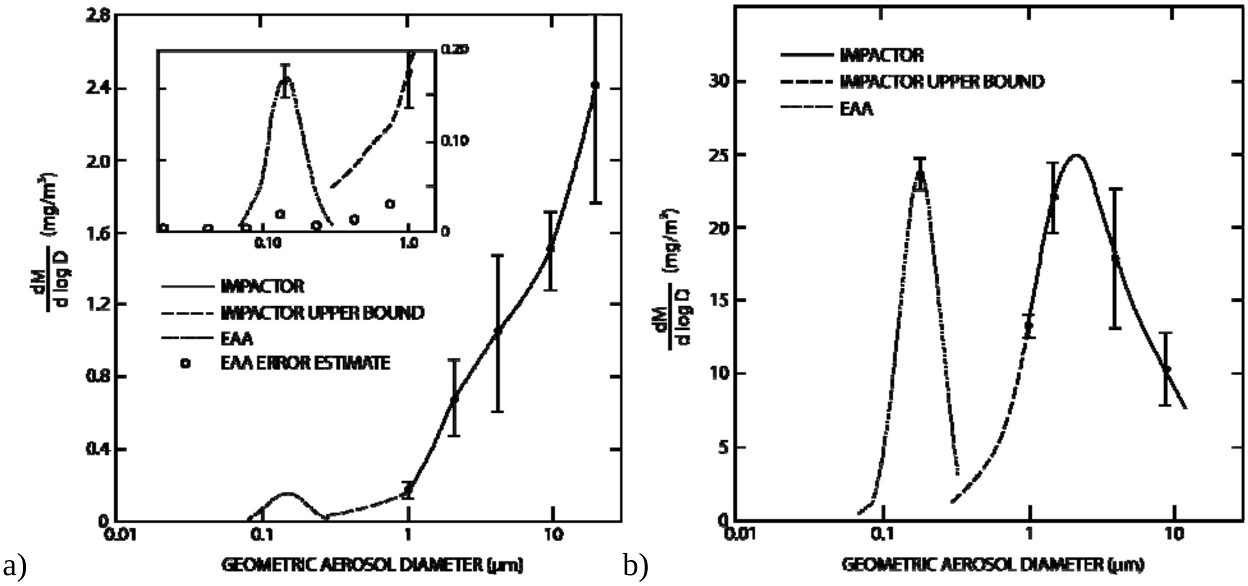

Figure C-6. Typical differential mass distributions of particulate collected a) upstream and b) downstream of an ESP (Markowski and others, 2000).

Fly ash produced upon the combustion of high sodium lignites in a pulverized coal (PC) fired system shows significant enrichment of sodium in the smaller size fractions as shown in Figure C-7. This figure illustrates the increase in the sodium content in the finer size fractions of ash as a result of firing high sodium lignite. The sodium and sulfur content of the less that 3 micrometer size fraction of the sampling train approached 20% Na_2O, and 25% SO_3. The form of the sodium is likely sodium oxide and sulfate.

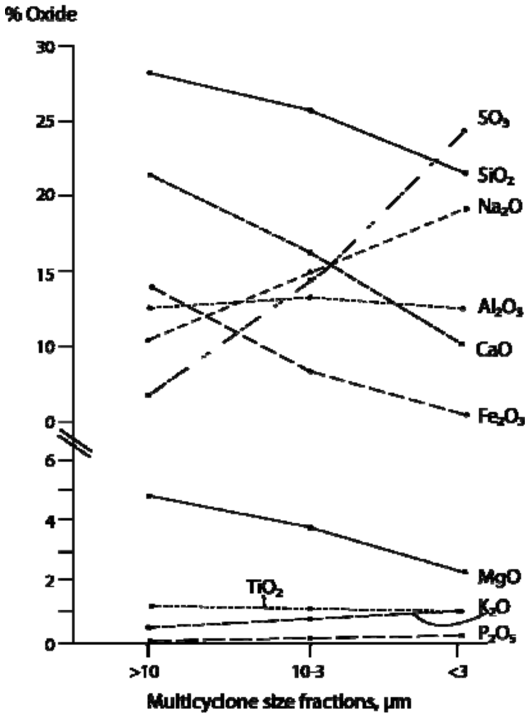

Figure C-7. Composition distribution of ash particles during combustion of North Dakota Lignite (Benson and others, 1984).

Electrostatic precipitator collection efficiency

The classical curve for ESP particle collection efficiency is shown in Figure C-8. This curve is typical of well behaved ash materials that do not present significant problems in collection. The collection efficiency is very good for particles greater than 5 to 10µm and the collection efficiency decreases with decreasing particles size with minimum collection efficiency between 0.2 to 2 µm in diameter. The collection efficiencies vary significantly because of particle size and composition.

Low collection efficiency for difficult to collect particles is between 0.1 to 1 µm in particle diameter. Figure C-9 provides an illustration of the range of collection efficiencies. Based on EPA education modules, no air pollution control device shows high collection efficiency in this range (0.1 to 1.0 µm) due to inherent limitations of the collection devices and particle characteristics (http://www.epa.gov/apti/bces/module3/collect/collect.htm). The following mechanisms of particle capture are impacted by the size of the particles:

- Inertial impaction and interception
- Brownian diffusion
- Gravitational settling
- Electrostatic attraction
- Thermophoresis
- Diffusiophoresis

The EPA (http://www.epa.gov/apti/bces/module3/collect/collect.htm) has indicated that based on a number of studies of actual "*sources stationary sources generating high* *concentrations of particles in the 0.1 to 0.5 micrometer range may be an especially challenging control problem. … The gap is most noticeable in wet scrubbers and electrostatic precipitators.*" A generalized plot showing the range of collection efficiencies is shown in Figure C-9. Overlaid on the diagram is the mass size distribution of particles collected downstream of the ESP wet FGD at the MRY plant (Markowski and others, 1983). This shows that ash produced in the MRY plant have a particle size that can pass through the scrubber and that these particles are rich in sodium as shown in Figure C-7.

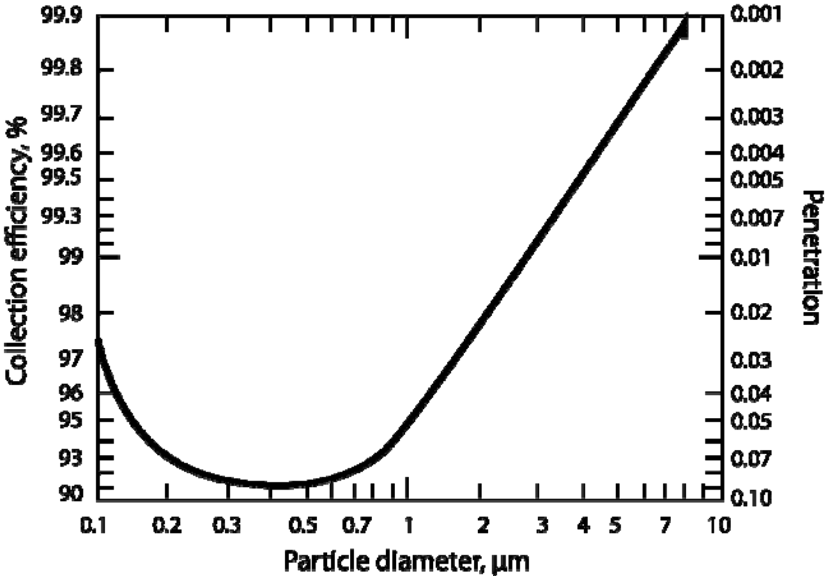

Figure C-8. Typical ESP Collection efficiency curve for removal of particulate from gas streams (http://www.epa.gov/apti/bces/module3/collect/collect.htm).

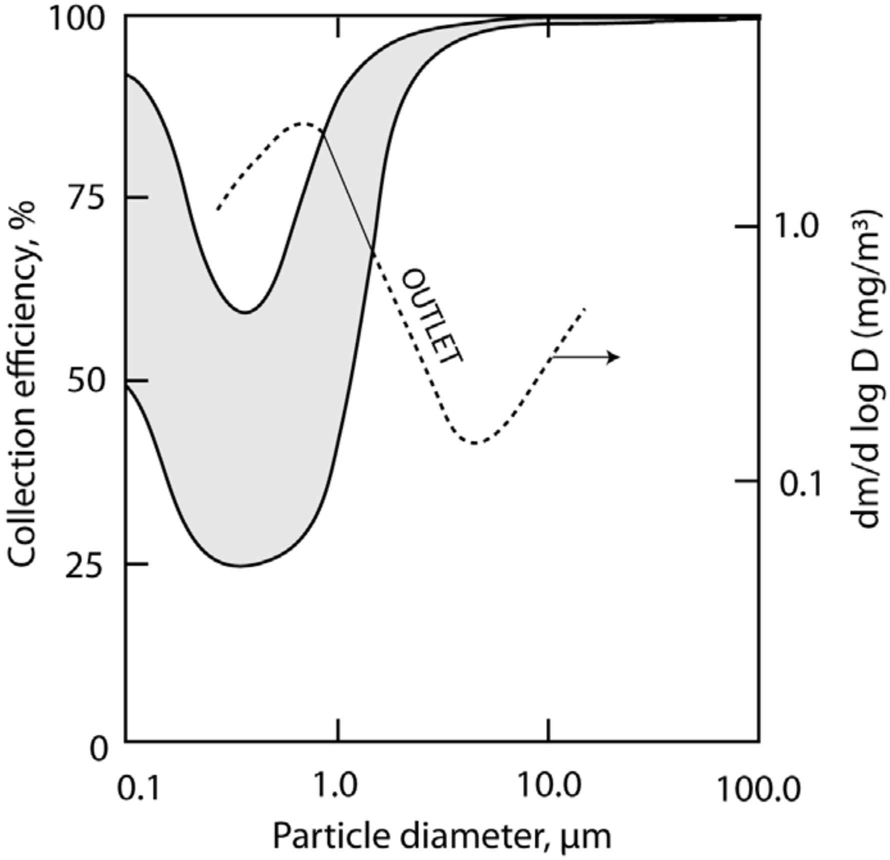

Figure C-9. Particulate control efficiency for difficult to control particulate combined with the mass distribution of particulate collected downstream of the scrubber at MRY (Markowski and others, 1983, http://www.epa.gov/apti/bces/module3/collect/collect.htm)

Field Experience and Testing

As indicated by EPA (Woodward, 1998), scrubbers do not effectively remove particulate less than 1µm in diameter. There is significant evidence that sodium-rich aerosols penetrate ESPs as well as scrubbers at full-scale power plants when firing high-alkali-containing fuels. An example is a biomass fired system using a tower type scrubber where the removal efficiency of the smaller size fraction of ash is low, as shown in Figure C-10 (Ohlström and others, 2006).

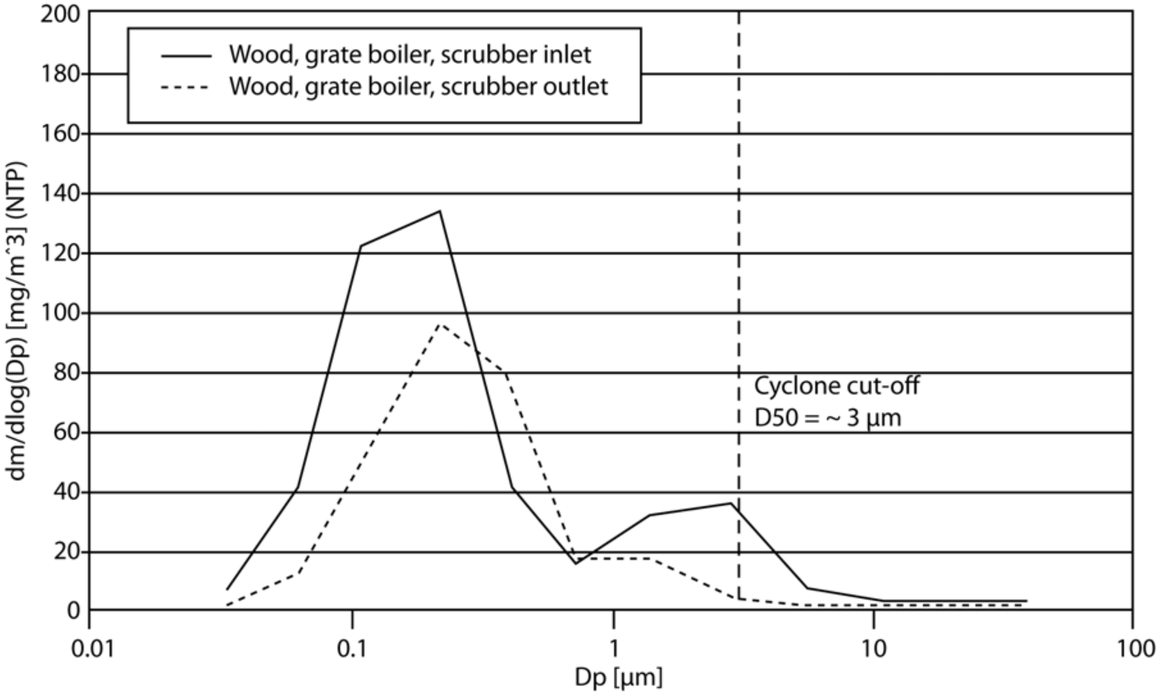

Figure C-10. Removal of fine aerosols using a scrubber on a wood fired combustor (Ohlström and others, 2006).

Minnesota Power's Boswell Energy Station found that when it fired high-sodium, lower-ash northern Powder River Basin subbituminous coal (7% Na_2O in the ash), it experienced increases in opacity. Hurley and Katrinak (1992) conducted a field-testing project on Unit No. 4, a pulverized coal-fired boiler equipped with a venturi wet scrubber, to better understand the reasons for the opacity problems. During the field testing, sampling of the coals, flue gases, and scrubber materials was conducted. The particulate in flue gases downstream of the scrubber was aerodynamically classified using multicyclone followed by an impactor and a Nucleopore filter. The sized fractions were weighed and analyzed to determine the abundance and composition of the submicron-sized fractions. The mass loadings in the various size bins are plotted in Figure C-11, showing that the scrubber is quite effective in removing the larger particles. However, the scrubber is not very effective in removing the aerosols less than 1 micrometer in diameter for both the blended coal and the high sodium coal (Coal A).

The results of the study indicated that the particulate collected downstream of the scrubber was coal-related and caused by the high sodium content of the coals. Vapor-phase sodium condenses in the boiler's convective pass to form fine sodium-rich aerosols or other Na species that later react with ash particles. Pure Na_2SO_4 particles are too small to be removed by such scrubbing. Figure C-12 shows the spikes of the ash material collected on Stage 10 of the impactor. This impactor accumulation represents particles of less than 0.7 to 2.5 micrometer size fraction of the submicron aerosol. The spikes are made up of submicron particulate matter, and the chemical analyses of the spikes and ash particles collected on the Nucleopore filters downstream of the impactor plates are shown in Table C-4. Both samples are dominated by sodium and sulfur that are likely in the form of sodium sulfate. These sulfate materials exhibit highly cohesive tendencies.

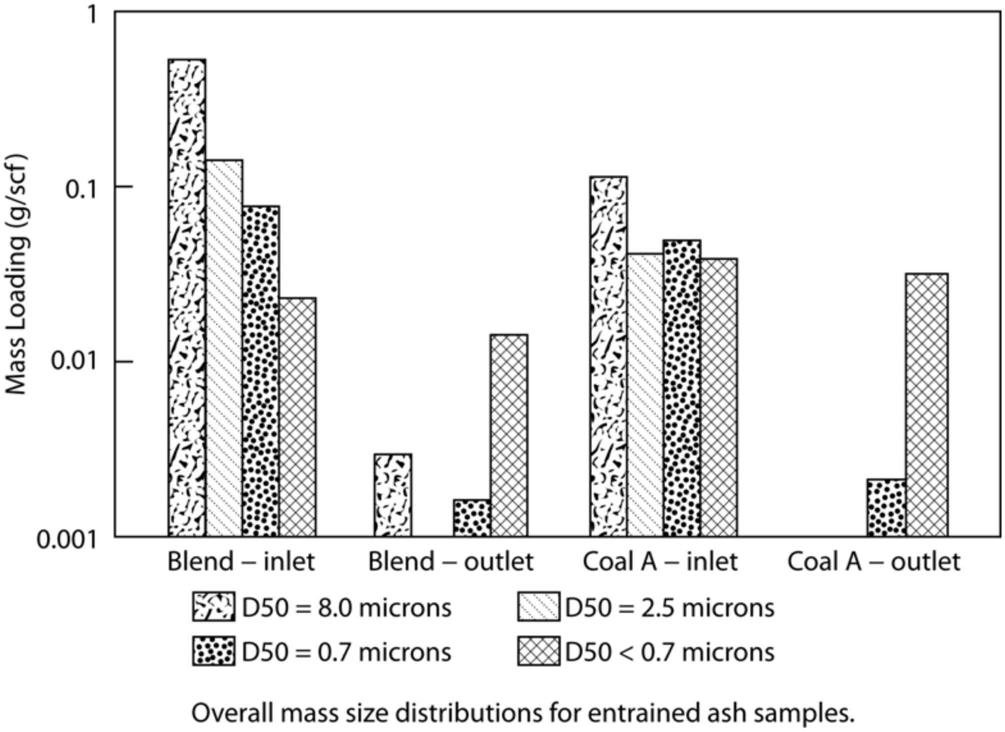

Figure C-11. Mass loadings and size for particulate collected upstream and downstream of the wet venturi scrubber at Clay Boswell (Hurley and Katrinak, 1992).

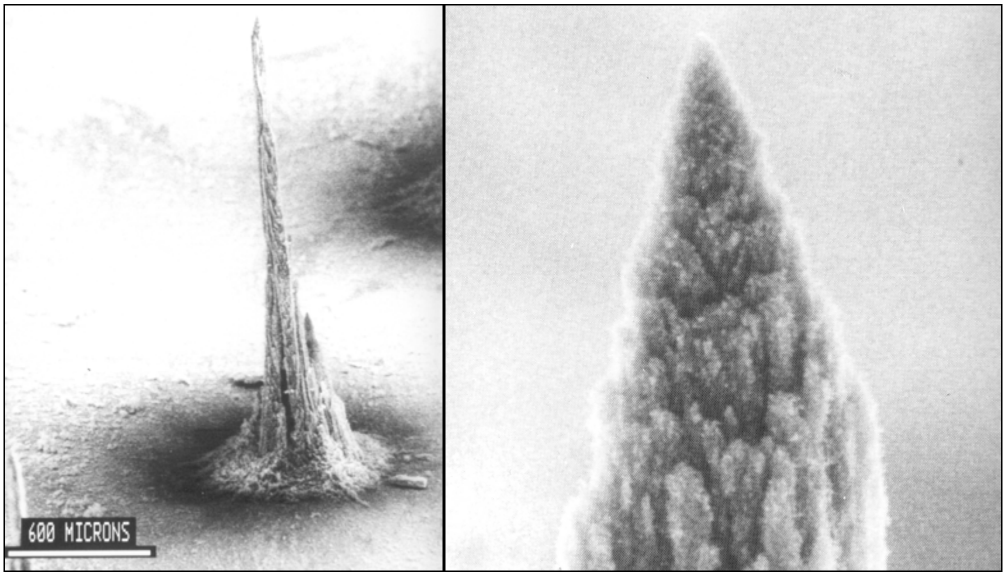

Figure C-12. Scanning electron microscope images of spike formed on impactor plate upon combustion of high-sodium subbituminous coal (right - close-up of spike) (Hurley and Katrinak, 1992).

Table C-4. Chemical Composition of the Spike Shown in Figure C-12 and the Filter (weight percent expressed as equivalent oxide).

	100% Coal A	
Oxide	**Spike**	**Filter**
Na_2O	**35.1**	**17.3**
MgO	1.4	7.8
Al_2O_3	2.0	9.8
SiO_2	9.1	10.6
P_2O_5	0.4	0.2
SO_3	**39.7**	**28.0**
K_2O	2.6	1.5
CaO	6.2	15.7
TiO_2	0.2	1.8
Cr_2O_3	1.4	0.1
Fe_2O_3	0.9	2.9
BaO	0.5	2.6

In addition to the aforementioned testing results, penetration of submicron particles through ESP and scrubbers has been reported by numerous researchers (Markowski and others, 1983, and Lighty and others, 2000).

Power Span Testing at MRY

Aerosols passing through the ESP at MRY Unit 1 resulted in significant accumulation on Powerspan's ECO barrier discharge reactor resulting in significant degradation in performance. The ECO DBD reactor is located just downstream of the plant's ESP or fabric filter (FF) and can be exposed to aerosols. The DBD reactor has quartz electrode rods inside where electric current is passed in order to generate the plasma used to oxidize NO. The temperature of the flue gas at the DBD reactor ranged between 300°F and 350°F. The temperature of the quartz electrodes is approximately 100°F higher than the gas temperature.

The Powerspan ECO reactor slip stream system was designed by Powerspan and the EERC. The slip stream system was installed by the EERC at Minnkota Power Company's Milton R. Young Station Unit #1 down stream of the ESP where the flue gas temperature was ranged from 300°F to 350°F. The system was commissioned on July 3, 2007, operated for 107 days. Operational performance of the system was monitored and data were archived for post processing. A pair of electrodes were extracted and replaced on a bi-weekly basis. Each pair of electrodes were shipped to Powerspan for testing in their laboratory reactor. Tested electrodes were then shipped to the EERC for scanning electron microscopy imaging and x-ray microanalysis. Measurement of NOx conversion by the slip stream system was not possible due to the nitric acid production of the DBD reactor.

The operational observations, performance results, and lab testing showed that the system was adversely affected by ash fouling. NOx conversion by ash covered electrodes was significantly reduced. Figure C-13 compares rods exposed to flue gas and aerosols downstream of the ESP at MRY Unit 1. The abundance of sodium in coal fired during the Powerspan testing is shown in Figure C-14. The results show sodium levels measured by the full stream elemental analyzer (FSEA) ranged from 3.5 to 6 % Na2O in ash. Figure C-15 shows the degradation in NO conversion as a result of being coated with aerosols. The NO conversion was severely impacted.

Figure C-13. Comparison of (left) clean quartz rod and (right) dirty quartz rod exposed to flue gas downstream of ESP at MRY Unit 1 for sixteen days.

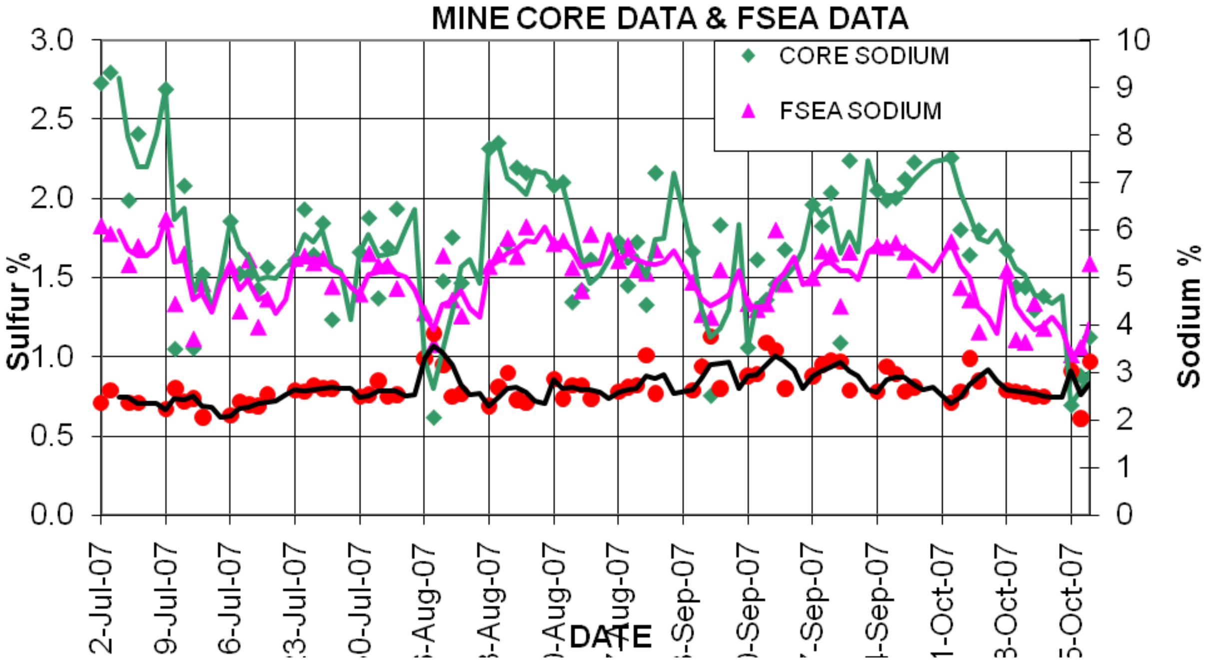

Figure C-14. Sodium and sulfur levels in lignite delivered during testing of the Powerspan barrier discharge reactor.

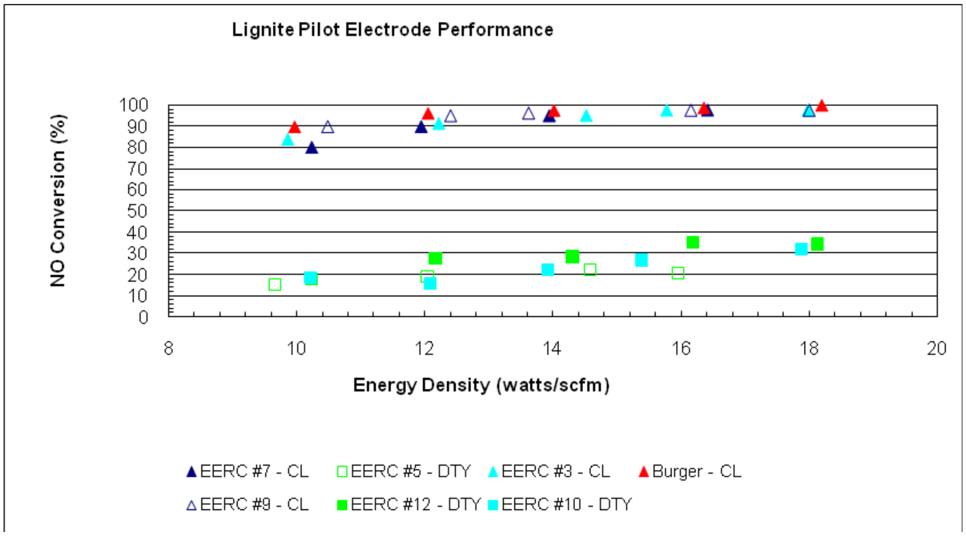

Figure C-15. NO conversion for clean (CL) and dirty (DTY) for quartz tube exposed the flue gas during the MRY testing.

Examination of the quartz rods (cross-sectioned to expose coating thickness) using scanning electron microscope elemental analysis showed significant elemental sodium, sulfur, and calcium in the ash coating the tubes after only 16 days of testing. The data is reported on Figure C-16. The thickness of the layer was approximately 25 µm. The rods were exposed to sootblowing. Images of the reactor and coatings on the electrodes are shown in Figure C-17.

Figure C-16. SEM point analysis on electrode #11 (16 days of service).

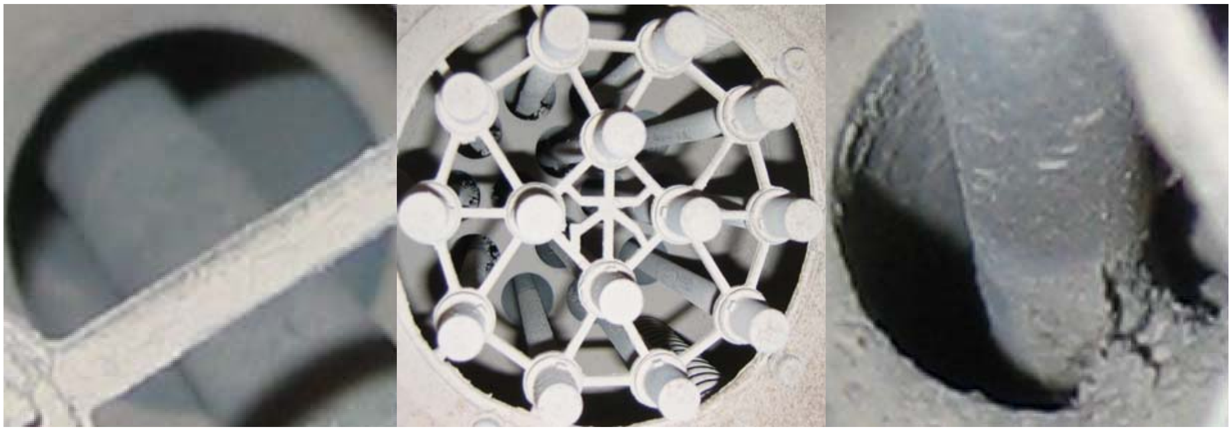

Figure C-17. Images of top of DBD reactor showing ash accumulations on electrodes and reactor surfaces.

Conclusions gained by this work were:

1. Sodium rich aerosols and small ash particles that had penetrated the ESP accumulate and become bonded on the surface of the silica electrodes in spite of soot blowing using a sonic horn as recommended by Powerspan.
2. Ash accumulations adversely affected the NOx conversion.
3. The adverse impact occurs within a two week time period.

MRY Sulfate Aerosol Sampling

The penetration of aerosols through ESP and wet scrubbers is well known and has been studied since the mid 1970s (McCain and others, 1975; Ensor and others, 1975). As a result of these challenges, the quantity of total aerosols and sulfate aerosols was measured at the MRY by Markowski and others, 1983. Markowski and others (1983) collected EPA Method 17 particulate samples and size-segregated the particles using an impactor (aerodynamically separates particles and allows for the characterization of each fraction). The results of the EPA method 17 sampling (mass concentration) conducted over a four-day period are illustrated in Figure C-18 for the inlet and outlet of the scrubber. At the inlet, aerosol mass concentrations ranged from a high of more than 10,000 µg/m^3 to a low of 4,000 µg/m^3. Significant levels were also found at the scrubber outlet, ranging from 8,800 to 2,500 µg/m^3. The removal efficiency varied from -25 to 66%.

Markowski and other (1983) offered no explanation of the differences in the levels of aerosols measured in the flue gas and removal efficiency. They did not consider that the ash content of the coal varied significantly during the testing. Results of testing at MRY have shown significant differences in the quantity vaporized for coals that have different ash contents (see Figure C-3). The variations in ash content shown in Figure C-18 reflect changing coal characteristics that resulted in differences in aerosol mass concentration.

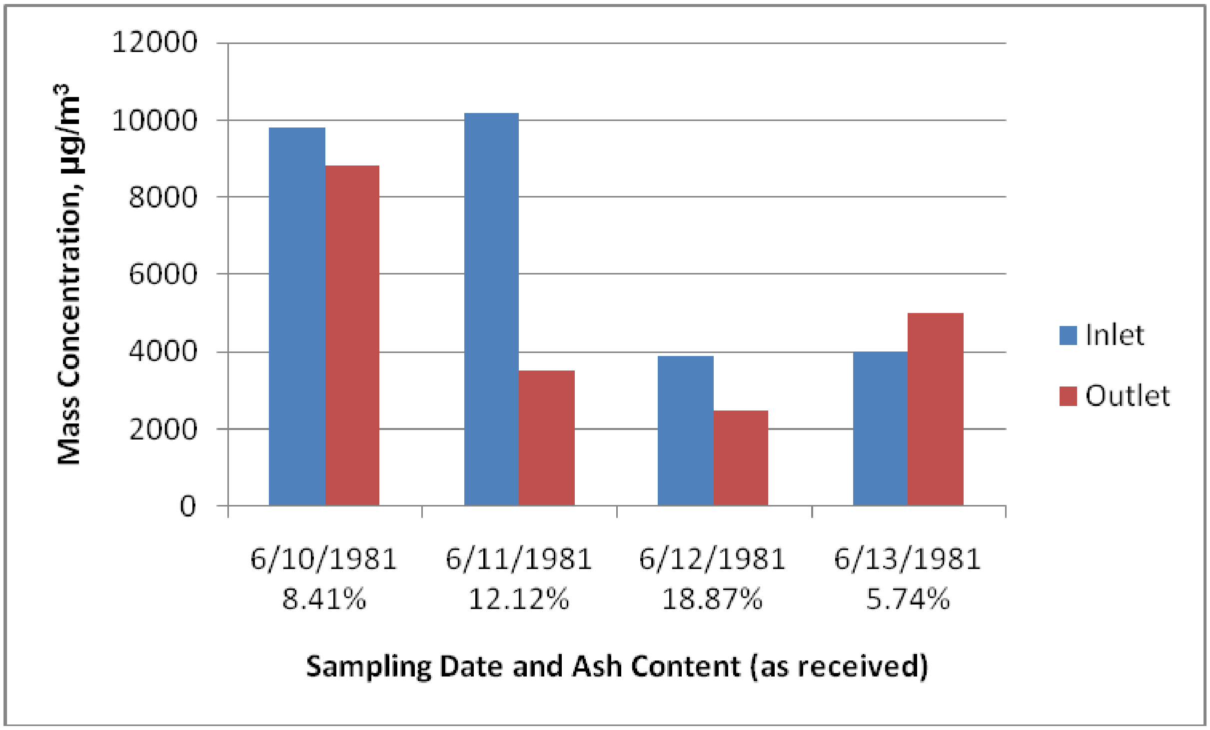

Figure C-18. Mass Concentration of Aerosol Collected at MRY Unit 2 at the Scrubber Inlet and Outlet (Markowski and others, 1983).

The results of the measurements of aerosol capture are illustrated in Figure C-19. The results show that aerosols less than one micrometer in diameter are not effectively captured in the wet FGD at the MRY facility. The graph also indicates the penetration of the particles through the FGD as a function of particle size. The penetration is the outlet size distribution divided by the inlet size distribution. (*Note: Penetration = 1- efficiency*). Markowski and others (1983) showed that the "metallic" sulfate aerosols (sodium sulfate) penetrated the FGD much more effectively than the larger particulate materials.

The mass of each of the impactor size fractions for the aerosols collected at the inlet and the outlet of the wet FGD upstream and downstream of the scrubber are illustrated in Figure C-20 and 21 with the results tabulated in Table C-5. The total mass distributions are summarized in Figure C-20 and the sulfate mass distribution is illustrated in Figure C-20.

Based on the impactor data the total mass of particulate that penetrates the scrubber is 5990 µg/m^3 (Markowski and others, 1983). These ash materials consist of a combination of sulfates and oxides of sodium, calcium, and sulfur. Much of the aerosol is present in the >14 µm size fraction. There are also significant mass in the less than 1 µm size fraction. All of these particles have the potential to penetrate the pores of the catalyst. In addition, there is a significant mass in the <0.26 µm fraction. This fraction represents the ultrafine component that has been implicated as the most significant contributor to catalyst poisoning (Kling and others, 2007).

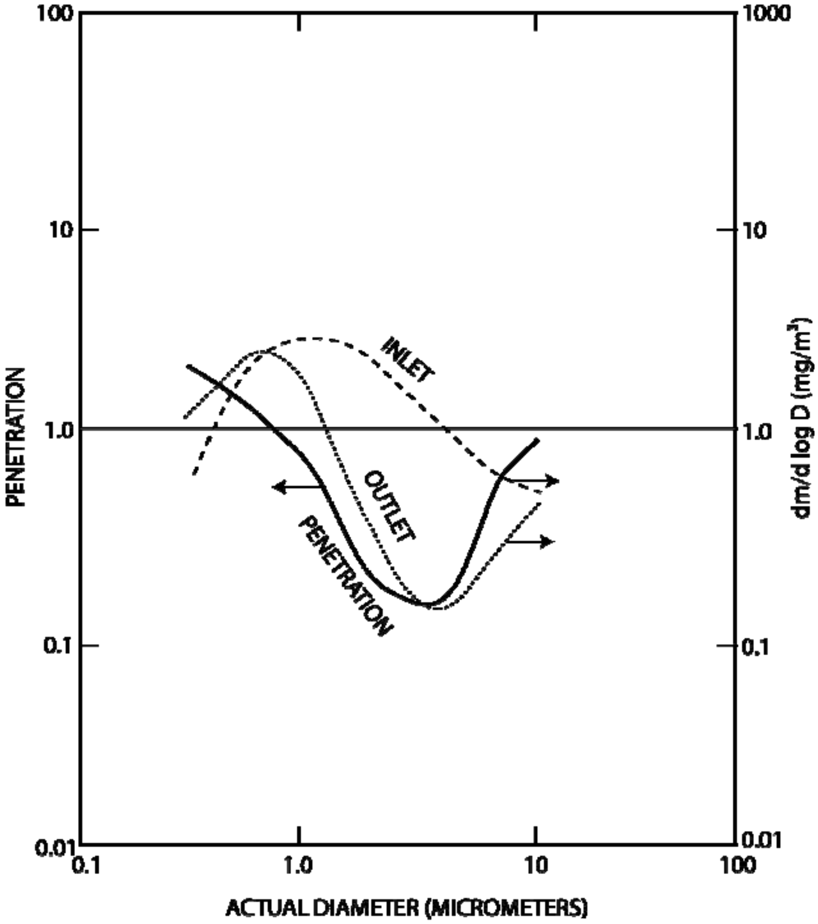

Figure C-19. Penetration through the wet scrubber (Markowski and others, 1983).

Table C-5. Size-segregated total and sulfate particulate collected upstream and downstream of the MRY FGD. (Markowski and others, 1983).

	Inlet	Outlet	Inlet	Outlet
Size, µm	Total, µg/m^3	Total, µg/m^3	Sulfate, µg/m^3	Sulfate, µg/m^3
<0.26	1910	769	436	602
0.26-0.52	401	640	164	274

Figure C-21. Sulfate particulate removal across scrubber at MRY.

Estimation of Alkali Aerosol Loading and Catalyst Deactivation

The following data was used to estimate alkali aerosol loading and catalyst deactivation. The particle loading was based on the results of testing conducted by Markowski and others (1983) where they determined the mass loadings of aerosols at the inlet and outlet of the wet FGD at MRY Unit 2. The key data utilized is illustrated in Figure C-22 to estimate the loadings. The data provided shows a range of mass concentrations up to 8,800 µg/m^3 at the outlet of the scrubber. Based on results in mass size distribution of the aerosol 47 to 80% of the aerosols that pass through the scrubber is less than 1.1 µm. Much of this material is in the ultrafine fraction.

These materials have the potential to penetrate into the catalyst causing plugging and can react with active components in the catalyst. There are numerous publications supporting these mechanisms. Kling and others(2007) found that the rate of catalyst deactivation was related to the accumulation of sodium and potassium on the catalyst as shown in Figure C-23 and 24. The work by Kling and others (2007) is consistent with the work conducted by Khodayari (2001) illustrated in Figure C-25 where it was shown that the deactivation rate is more significant for PC fired systems as compared to fluidized beds. The work based on Kling and others when applied to PC- and cyclone-fired systems will likely underestimate the degree of deactivation because of the firing methods.

Table 4 – MRYS Unit Design and Operating Parameters

Design Unit Operating Characteristics(1)	Unit 1 Design	Unit 2 Design
Boiler Type	Cyclone	Cyclone
Boiler Manufacturer	B&W	B&W
Boiler Design Heat Input Capacity (nameplate), mmBtu/hr	2,510	4,696
Unit Nameplate Generator Output Capacity, MW_g (gross)	257	477
Unit Nominal Full Load (NFL) Output, MW_g (gross)	235	450
Boiler Heat Input for Unit NFL Output, mmBtu/hr	2,508	4,814
Boiler Excess O_2, %, (wet, NFL)	3.17	4.04
Boiler Excess Air, % (NFL)	21.3	28.5
Fly Ash Portion of Total Ash, % (NFL)	45	50
Typical Maximum Continuous Rating (MCR) output, MW_g	253	462
Maximum Unit Output (URGE) Rating, MW_g	278	512
Boiler Firing Conditions for Flue Gas Flow Calculations:		
Boiler Heat Input, mmBtu/hr	2,852	4,740
Coal Higher Heating Value, Btu/lb as-received	6,578	6,578
Coal Flow Rate for heat input, lb/hr	433,500	720,500
Fly Ash Portion of Total Ash, %	50	50
Flue Gas Conditions at the boiler flue gas outlet:		
Boiler Excess O_2, %, (wet)	2.87	4.77
Boiler Excess Air, %	19.0	35.4
Flue Gas Mass Flow Rate, lb/hr	3,811,000	7,117,000
Flue Gas Volumetric Flow Rate, acfm	2,502,000	4,371,000
Flue Gas Temperature, degrees F	910	818
Flue Gas Pressure, in. w.g.	-11.5	-13.5
Boiler Outlet Maximum SO_2, lb/mmBtu	3.0(2)	3.0(2)
Boiler Outlet Maximum SO_2, lb/hr	8,970	15,474
Average Boiler Heat Input for SO_2, mmBtu/hr	2,990	5,158
Expected Boiler Outlet Maximum 30-day average SO_3, lb/hr	135(3)	236(3)

(1) – Boiler unit operating parameters are provided for more than one load or output condition.

(2) – Boiler Outlet Maximum SO_2 lb/mmBtu is based on 1.0% S and 6,578 Btu/lb higher heating value content in the as-received lignite coal.

(3) – Boiler Outlet Maximum SO_3 lb/hr is based on the assumed conversion of 1.5% of the boiler outlet SO_2 to SO_3 upstream of any flue gas treatment. This conversion percentage has not been confirmed by actual boiler outlet flue gas test measurements. The SO_2 lb/mmBtu and lb/hr values have not been reduced by this assumed SO_3 conversion.

Table C2 summarizes the average, maximum and minimum values for the entire as-fired coal database. The ranges on the various components can be very large. For example, the ash content ranges from 5 to 25%. Sodium oxide content ranges from 0.6 to 13% of the ash.

Table C2. Average, maximum, and minimum of basic coal analysis for all the coals in the as-fired database - Center Lignite Coal

ID NUMBER	Moisture	Ash	Sulfur	Btu	Volatile Matter	Fixed Carbon	Aluminum Oxide	Barium Oxide	Calcium Oxide	Iron Oxide	Magnesium Oxide	Manganese Dioxide	Phosphorus Pentoxide	Potassium Oxide	Silicon Dioxide	Sodium Oxide	Strontium Oxide	SO3	Titanium Dioxide	Basic total	Acid Total	Base/Acid Ratio

1. Ash weight percent was determined on an “as-fired” lignite coal basis.
2. BTU (higher heating value) content expressed on an “as-fired” lignite coal basis.
3. Constituent weight percent of the ash, elemental weight percent expressed as equivalent oxide.
4. B/A is the base to acid weight ratio of the ash constituents (B/A=[Na_2O+MgO+CaO+ K_2O+FeO]/[SiO_2+Al_2O_3+TiO_2]).

Bob,
Attached are the preliminary PFDs for Minnkota. Volker and I have yet to discuss these in detail, but we should be able to finalize them by the end of the week.

We can review these later at your office.

Thanks, Bob

Attachments: Risiko_SINOx_E.pdf; GGH Brochure.pdf

Bob,
Thanks for compiling the discussion minutes. Volker and I have discussed these once and plan to do so again tomorrow. I will summarize our comments and send them along.

But, all of the attachments in your message are the same, though titled differently.

Attached is a brochure of the Hitachi FGD GGH that they have installed in Japan. it may be suitable and you may find the information useful.

Also, in anticipation of a response from the catalyst suppliers, I studied the Na concentrations from the tests at MRY. If I calculated correctly, 5,000 to 10,000 micrograms/Nm^3 are approximately 3 to 6 ppmv or 3.2 to 6.4 mg/Nm^3. according to Argillons Risk Analysis, this is right at the edge of their range. Let's see what Ceram and Topsoe have to say.

Best Regards, Bob

Subject: RE: LD and TE SCR Review and Recommendations for MRYS

Bob and Volker -

Here are the latest BMcD conceptual layout drawings of the ductwork and SCR/GGH "towers" that assume the Babcock Power approach for low-dust and tail end SCCR configurations. We are looking at one reactor for Unit 1 low dust or tail-end, and two reactors in parallel for Unit 2 low-dust or tail-end. We are looking for you to provide a review looking for "fatal flaws" or issues that could have significant impacts on function, performance, and capital cost.

Comments from our discussion with Bob in our office 9/1/09:
Our main concern is the potential leakage of untreated flue gas from the FGD GGH on the inlet side of the scrubber to the outlet side of the scrubber must be very close to zero, as any significant amount will make it difficult or impossible to maintain 95% SO2 removal across the wet scrubber. BPEI appears to be using a rotary regenerative type gas-gas heat exchanger for these SCR applications for both the FGD and SCR GGHs. They have not provided any details on these GGHs other than what we have already provided to you for review.

This approach does not reflect Steve Voss' idea raised this morning that the warm (dirty) side of the FGD GGH inlet be connected before the ID fan, so that any leakage would tend to be from the treated gas to the dirty gas side because of the higher pressure after the scrubber than before the ID fan.

We asked if there are other GGH options that have been proven successful in heat recovery-SCR operation that avoid the leakage issue. You said you could provide us with more information on such equipment.

We need to know where any special materials of construction may be required for corrosion resistance that are not obvious, such as after the tail-end SCR reactor to the chimney inlet, and the booster fan for this same location. This gas stream entering the fiberglass-reinforced plastic Unit 2 chimney liner must be less than 200 degreesF continuously, although it will tolerate 400 degrees F upset for 15 minutes. We plan on adding an emergency quench header to protect the fiberglass liner and any ductwork from failure of the TE SCR GGHs. Because the flue gas downstream of a TE-SCR may have some SO3 that has been oxidized from SO2 remaining in the gas after the scrubber removes 95-97%, we welcome your comments on duct and fan materials.

We asked about startup of a LD- or TE-SCR after an extended boiler outage where everthing is cold. Does the flue gas need to be warmed up inside the reactors before exposing the catalyst to coal flue gas, especially for tail end where the GGHs don't have much heat to recycle?

How long could it take to cool down the reactor and remove and replace the catalyst was also of interest.

It would be helpful if you could provide some idea regarding possible budgetary cost and schedule estimates for a slip stream pilot SCR test program - low dust and tail-end configurations, from start to getting the results analyzed after operating for a significant amount of time with a suitably sized reactor and system that simulates low-dust and tail-end SCR conditions.

We'll be interested in further discussions once we have received the updated preliminary mass balances and other information. Let us know if you have any questions.

Thanks,

Bob Blakley

Subject: RE: LD and TE SCR Review and Recommendations for MRYS

Bob -

Thanks for calling me back and letting me know you are available for low-dust and tail-end SCR discussions for the Minnkota SCR Cost study project here in our office on Tuesday, 9/1 at 10 am.

Ron Bryant is arranging for food (pizza) so you can stay and join us for that if you wish.

I see this starting with the process review (updated preliminary mass balances and process flow diagrams), and then moving to the conceptual design review of the various SCR layouts, discussion of duct materials, booster fan locations, materials, and design pressure rise considerations, and then review of auxiliary systems.

I looked for the photos of Mercer Station that you mentioned, but it wasn't where I thought its was saved on the server and Steve Voss wasn't here to ask.

Subject: LD and TE SCR Review and Recommendations for MRYS

Bob & Volker -

It's been awhile since we've emailed or talked. We hope you've been enjoying the summer weather. It's been relatively benign here in Kansas City.

We have been asked to proceed with performing a cost study and BACT cost effectiveness update for Minnkota's Unit 1 and Unit 2 involving low-dust and tail-end SCR technology. We are committed to having a draft cost study report to Minnkota for review by September 30, so we hope that you will be able to assist in this effort in the short term.

1. Update previous March 2009 LD and TE SCR preliminary mass balance calaculations with process flow diagrams - assuming a nominal NOx baseline of 0.50 lb/mmBtu with overfire air then 90% NOx reduction (30 day rolling average). We need you to convert numbers in the PFDs to English units (lbs/hr, deg F, in. w.c.), assuming a single SCR reactor for Unit 1 and two reactors in parallel for Unit 2.

2. Review of BMcD conceptual designs of reactors, GGH's, ductwork, and isolation damper locations (based on BPEI approaches) for "fatal flaws". Our preliminary layouts are attached, based upon a low-dust or tail-end SCR reactor "tower" that was developed by a system supplier recently involved with two low-dust projects in the U.S..

3. Recommendations for booster fans' locations for low-dust and tail-end SCR applications. We assume that avoiding a "wet" fan between the wet FGD outlet and SCR GGH is desirable, as well as having the SCR reactor under negative pressure.

4. Review of BMcD's selections for materials of construction for ductwork, and recommendations for GGHs and SCR reactor isolation dampers for TE SCR systems, assuming both Units have saturated flue gas following the wet lime FGD absorbers.

5. Recommendations for SCR catalyst online cleaning (air "knife" sootblowing rakes) and GGH online cleaning, assuming that high-pressure compressed air is preferred over steam. Is water needed to flush condensed acids from the FGD-GGH plates? Is this a continuous consumption? What do we need to consider and include in our cost estimate?

6. Recommendations for standby (outage) catalyst heating system - what do we need to consider and include in cost estimate.

7. TE SCR pilot slipstream - approach, cost and schedule estimates.

We have a total of four estimates and conceptual designs that we are developing:
>low-dust SCR for Unit 1,
> low dust SCR for Unit 2;
> tail-end SCR for Unit 1,
> tail-end SCR for Unit 2.
There are a few common systems that we also expect could be shared between the Units - urea solution receiving and storage; urea solution feed/circulation [to Fuel Tech "ULTRA" urea-to-ammonia conversion system(s)]; individual or common "ULTRA" system(s) to decompose the urea to ammonia gas; individual high-pressure compressed air compressor and air receiver tank(s) for on-line cleaning of the catalyst; individual standby (outage) catalyst heating system(s) - can this use the "Ultra" system without urea injection to provide heated air when the boiler is shutdown for fireside cleaning outages 3 or 4 times per year?

We have engaged two SCR system suppliers and two SCR catalyst manufacturers to help with our conceptual design efforts and installed cost estimates, but there are several areas (noted above) that we think that your experience could help improve the quality of our conceptual design development work.

Please confirm your interest and availability to assist on this effort. We are running short on time and your help would be very beneficial.

HITACHI Non-Leakage Type Gas-Gas Heater

Hitachi Power Systems America
Basking Ridge, NJ

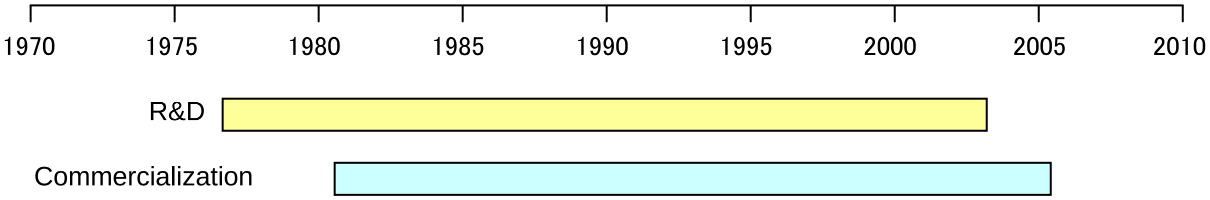
HITACHI
Inspire the Next

Technology Development

Babcock-Hitachi K.K.has started R&D activities for developing heat pipe technology in 1976. Since the first plant was delivered in 1978, Babcock-Hitachi K.K. has been working on the higher efficiency and rationalization of Gas-Gas Heater. Babcock-Hitachi K.K. has already delivered more than 10 non-leak type Gas-Gas Heater not only large-scale domestic power plant but also overseas, supported by boiler manufacturing technologies.

Non-leak type Gas-Gas heater is dispensable for stringent environmental emission.

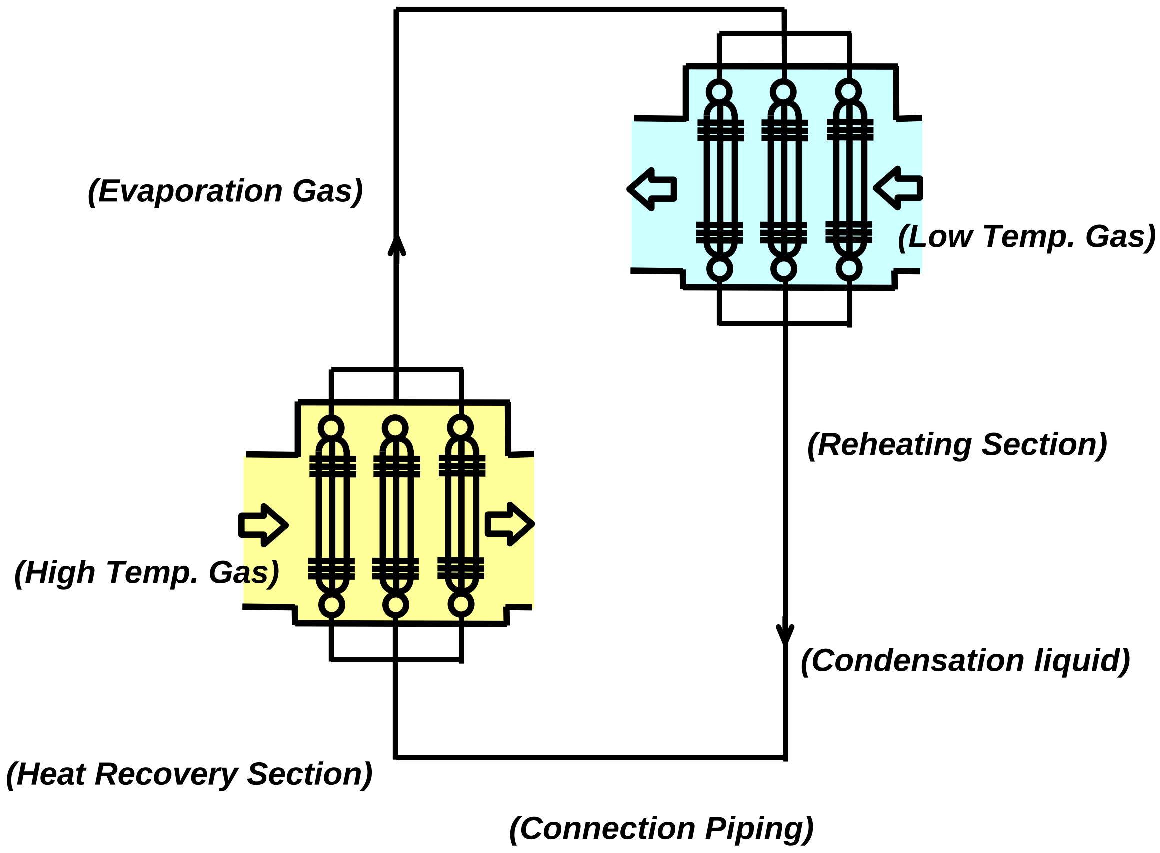
R&D and Commercialization Record



Application Concepts

(Heat Pipe Type)

A heat transfer medium,that is water, is hermetically sealed inside a vacuumed pipe container(Heat Pipe), which consists of a heat recovery (evaporation) section and a reheating (condensation) section. The transportation of the heat medium requires no power because of the use of gravity action,etc. Therefore this method requires no additional auxiliaries such as pumps, drives for rotation of heat exchanger unit which other heat exchangers do require.

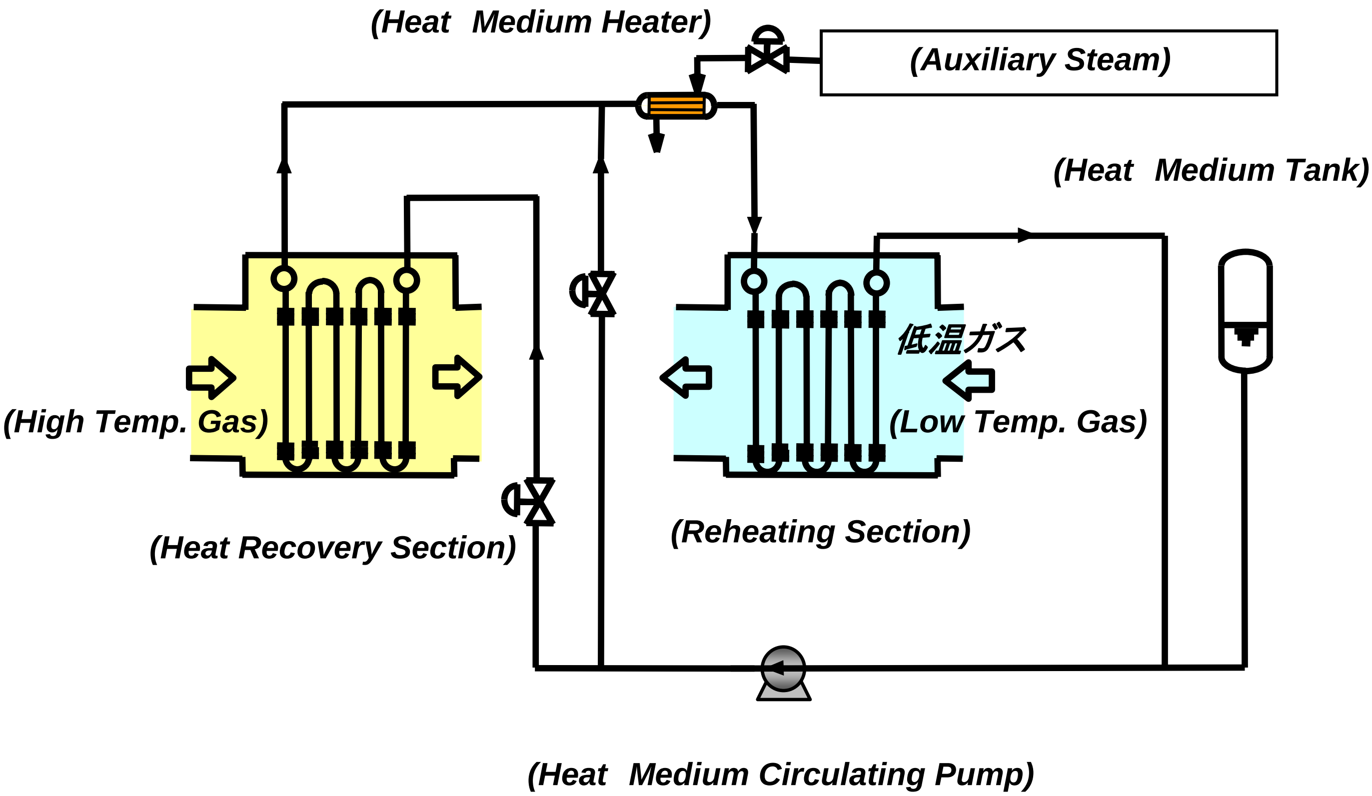


<u>Flow Diagram of Heat Pipe Type</u>

Application Concepts - continued

(Heat Medium Forced Circulated Type)

This type utilizes a pump forced hot water circulation system.Heat exchange between heat recovery section and reheating section can be achieved by circulating heat medium.
High temperature gas is cooled by heat recovery section, then low temperature gas is heated up to certain temperature by reheating section.
Although a heat pipe type needs to locate reheating section in a high position, this type does not have the restrictions on arrangement.



Flow Diagram of Heat Medium Forced Circulated Type

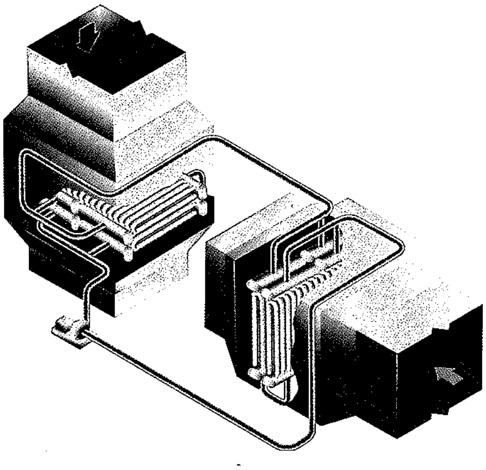
Features

EASY ARRANGEMENT

The heat recovery section and Reheating section are separated and are connected through re-circulation pipes.
This separate type helps to make duct arrangement easy.

NON LEAKAGE

There is no leakage of fluid. Therefore, this type can be used for Combustible fluid, Pressurized fluid, Poisonous fluid, etc. and can perform a high heat transfer efficiency.



Typical Configuration

Features - continued

EASY DESIGN FOR ANTI-CORROSION

Suitable material for the heat recovery section and reheating section can be selected separately.

EASY DESIGN FOR ANTI-CORROSION

By adopting the finned tube as heating tube, much heating surface area is obtained and compact arrangement is possible.
By adopting the optimal fin specification according to the flue gas composition, It makes long term stable operation possible.

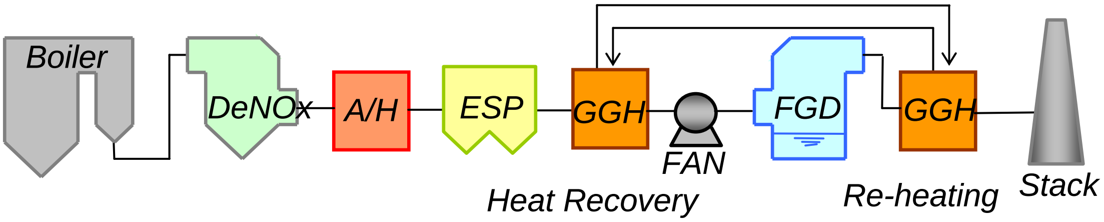
Heating Tube

The State of the Heating Tubes
(After 2 yeas of operation)

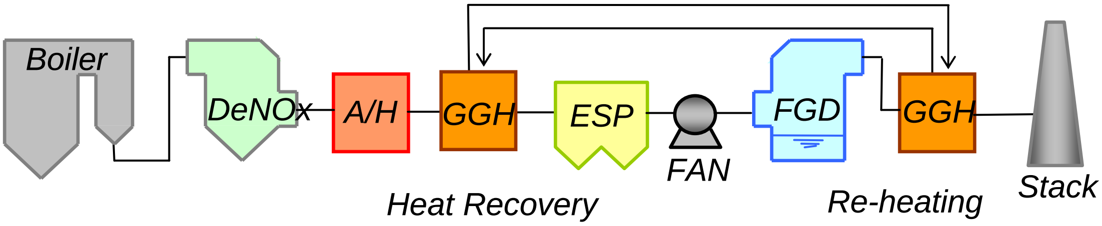
Applications

(1) (For FGD System)

TYPE —1



TYPE —2



In the FGD plant, it is necessary to make an exhaust gas re-heat as follows.

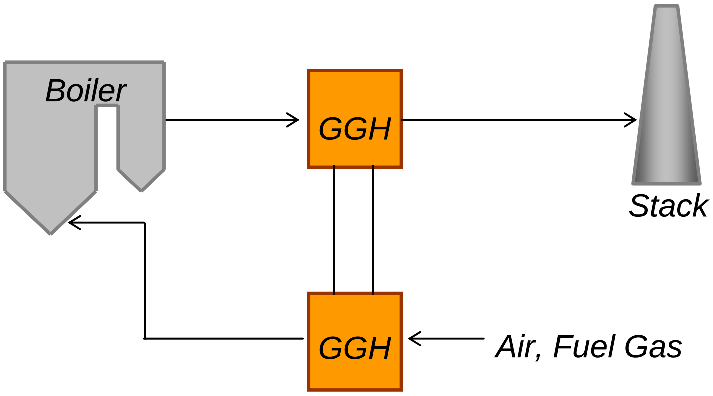
(1) Improvement of the Diffusion
(2) Prevention of the corrosion of Duct ,Stack
(3) Prevention of the visible gas

Babcock-Hitachi K.K. is one of the leader as the non-leak type Gas-Gas Heater which recovers heat from flue gas and reheat treated gas at the FGD without any leakage of untreated flue gas. According to more stringent emission, no leakage of untreated flue gas at the Gas-Gas Heater is dispensable for FGD instead of re-generative type Gas-Gas Heater.
To the 1990s, Type -1 was in use.
Recently, Type -2 which can improve the dust removal performance of ESP is becoming in use because of strengthening of regulations of dust emission

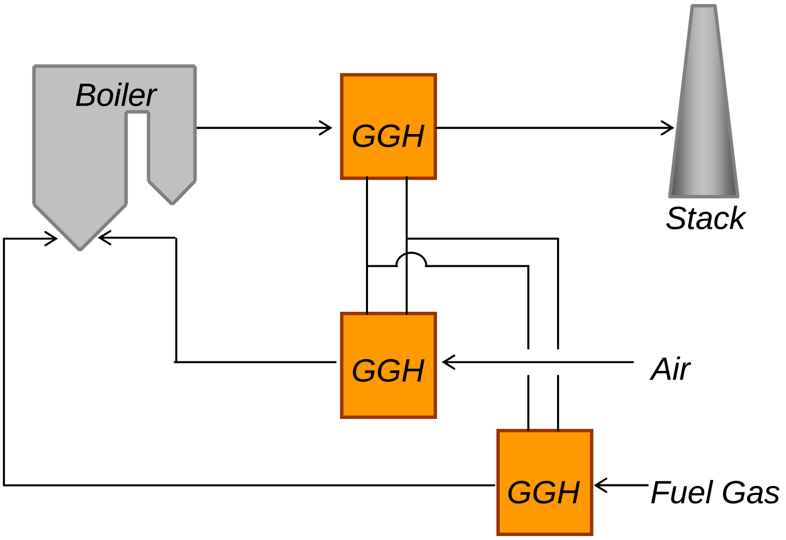
Applications - continued

(2) (For Fuel Gas/Air Preheat System)

TYPE −1



TYPE −2



Not only heat recovery of the boiler exhaust gas for power plant but reuse of various exhaust gases is possible.

Attachments:	11Sep09_MRY2TailEnd_Rev1_natgas.pdf; 11Sep09_MRY1LowDust_Rev1_natgas_580F.pdf; 11Sep09_MRY1TailEnd_Rev1_natgas.pdf; 11Sep09_MRY2LowDust_Rev1_natgas_580F.pdf

Bob,
Attached are updated PFDs and mass balance for the four options. We have added a table with flue gas constituents for the process.

After discussing the application some more, Volker and I recommend that the operating flue gas temperature for the LD cases should be raised to 580F. This is just to provide some margin pertaining to the minimum operating temperature of the SCR.

Also, as I mentioned in our discussion, these PFDs are still preliminary, pending selection of the GGH supplier and their opportunity to provide the balance around the GGH.

Volker and I are drafting comments re: other open items. We expect to issue this to you on Monday.

Best Regards, Bob

Low Dust & Tail End Selective Catalytic Reduction (SCR) Systems Comments

Conceptual Arrangement Drawings

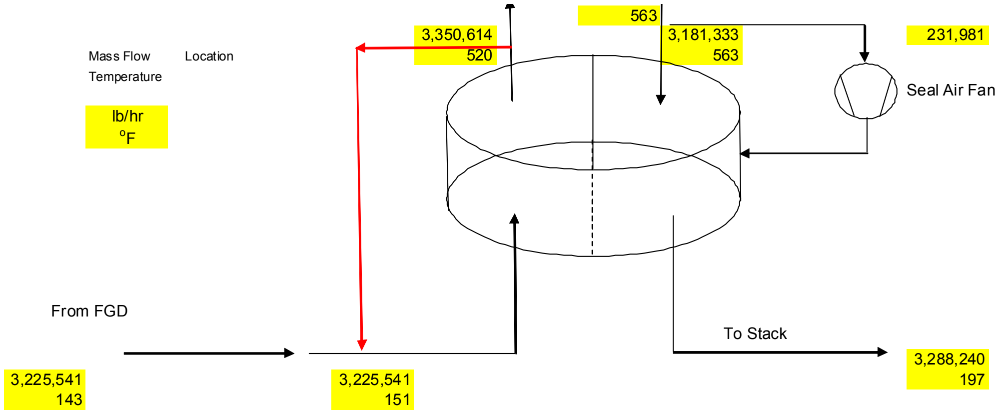
Fuel Tech has reviewed the initial arrangement drawings. Here are our comments:

- Based on what was provided, we don't see anything that could be considered a "fatal flaw."
- In general, there are two design considerations that deserve closer evaluation once we have the opportunity to review 3-D models:
  - Location of bypass dampers and ducts;
  - Duct transitions within the inlet ductwork and into the reactor hood. It is important to maintain uniform ammonia and flue gas distributions into the catalyst, and severe angles and transitions have significant effects.

Flue Gas Heating & FGD GGH Options

For Tail End systems, it is important for the flue gas temperature entering the SCR GGH to be above the water dewpoint. This will prevent condensation and potential corrosion within the GGH. There are a few methods for raising the FGD outlet temperature:

- FGD GGH: Regenerative type heat exchangers have been used in Europe for this application. When FGD systems were deployed in German powerplants, heat exchangers were needed to raise flue gas temperatures to >72°C for plume buoyancy. These same exchangers were integrated into Tail End SCR systems. Some corrosion issues have been documented. Some solutions that have been used include alloy elements, plastic elements, and enameled elements.
- FGD Heat Pipes: Another type of heat exchanger is the heat pipe technology, such as that marketed by Hitachi. Hitachi has installed this type of exchanger in Japanese plants.
- Flue Gas Heating with Duct Burners: Direct gas firing in the duct would eliminate the need for a heat exchanger. In contrast to the use of duct burners for maintaining flue gas temperature to the inlet of the SCR catalyst, continuous gas firing would be needed for controlling the flue gas temperature at the inlet to the SCR GGH.
- Heat Exchange Loop at the SCR GGH: Another method includes the use of a slipstream from the SCR GGH outlet back to the inlet to raise the inlet flue gas temperature. This alternative is shown below in red:



The latter two methods would affect the overall mass balance of the Tail End system, primarily due to the increased natural gas consumption by the duct burners.

A cost-benefit comparison of these alternatives should be prepared specifically for the MRYS installation.

Start Up Procedures

Start up procedures need to be specifically prepared for MRYS based on the final operating permit. In some cases, partial or full bypass of the SCR may be permitted for a certain period to allow the catalyst to be warmed to operating temperature before ammonia injection is permitted to commence. If bypass is not allowed, then other procedural methods will be developed for the MRYS installation.

One alternative is described here. After purging the entire flue gas duct work of the unit, FD and ID fans will ramp up to the highest capacity. The SCR GGH must be in operation. The SCR burners will be turned on to preheat the catalyst to operating temperature. Once this is established, boiler startup can be initiated and the bypass dampers to the SCR can be closed to permit flue gas to flow into the reactor. The reagent for the SCR can be injected immediately after the first fire in the boiler.

Other procedural methods may be developed in conjunction with overall system design, the final selection of a Tail End or Low Dust system, and the final permit for the plant if this kind of preheat is not acceptable.

Catalyst Exchange Information

In practice, catalyst loading, removal and exchange procedures vary widely among the operating SCR plants in the United States. It is our experience that Architect-Engineers, System suppliers, catalyst suppliers and Utilities have assimilated “best practices” and have developed site specific procedures. Unfortunately, we are unaware of specific and published comparisons or time & motion studies that document actual experience.

Fuel Tech knows specific procedures for some of our clients and we are aware of their experiences. In our opinion, it is not appropriate to use these particular experiences to validate other experiences or catalyst handling designs within the industry.

To achieve a specific requirement, such as a complete catalyst layer exchange within a certain period, the complete SCR system must be designed to accommodate this. For instance, catalyst module handling, storage, and movement must be consistent with the reactor platforms, access door number and location, catalyst transport systems from storage to platform, handling within the reactor and the number of personnel and shifts to perform the exchange.

Our "rule of thumb" estimate for catalyst installation is thirty (30) minutes per module. This is based on conventional access, use of hoists for module handling and transport, and a typical crew of 4 to 6 people. With a different system design and more personnel, the time period can certainly be reduced.

Catalyst Slipstream Test

Concerning the budgetary estimate and schedule for a comprehensive slipstream test, we suggest the following:

- The test should include a reactor large enough to house multiple catalyst types and layers;
- The test should run preferably nine (9) months to a year, in order to observe effects on the catalyst;
- An independent lab should be used to evaluate all of the catalysts at various intervals to develop trends;
- The operation of the test reactor needs to be monitored throughout the duration of the test for proper correlation of catalyst effects with flow and temperature.

Without specific details or requirements, we estimate the cost to design, build and install the test reactor to range from $400,000 to $600,000. Testing, operating and monitoring the program is estimated to cost $250,000 to $400,000 depending on the duration and final program.

Bob -

Please confirm the urea consumption rates and natural gas consumption for flue gas reheating recently provided for Unit 1 low-dust and tail-end SCRs.
These are for a single SCR reactor for Unit 1 in each of the two configurations.

Also advise on the status of the updated preliminary mass balance calculations for all 4 cases.

Let us know if questions arise.

Thanks for the comments on your review of our preliminary SCR arrangements. We will review and advise if we want additional comments that you may be able to provide.

Subject: Fuel Tech Flow Diagram Discrepancy

Robert,
I was reviewing the Fuel Tech flow diagrams to pull the urea and natural gas usages for the economic evaluation. I found that some of the numbers aren't adding up. If you compare the Sept 09 flow diagrams vs the March 09 diagrams, the urea and natural gas usages look off for the Unit 1 Tail End and Low Dust options. The ammonia values match fairly closely though. It looks like they may have forgotten that the March 09 numbers were based on two reactors while the Sept 09 numbers where only based on one reactor. The urea and natural gas numbers are half of what they should be. Attached is a spreadsheet that compares the two sets of data. Please verify this with Fuel Tech.

Subject: RE: Fuel Tech Flow Diagram and Mass Balanace Updates

Bob -

When updating the preliminary process flow diagrams and mass balance calculations, can you provide more information on:

1. flue gas reheat natural gas fuel consumption in million Btu/hr and SCFH in addition to mass flow (lb/hr)?

2. percent excess air and mass flow (lb/hr) of ambient combustion air assumed for the reheat burner natural gas firing?

3. FTI's ULTRA urea-to-ammonia system urea versus ambient dilution air mass flows (lb/hr)?

4. FTI's ULTRA urea-to-ammonia system natural gas fuel consumption in million Btu/hr and SCFH, and how much of the ambient dilution air is used in the combustion of the natural gas?

We are interested in also knowing the amount of NOx expected to be produced by the flue gas reheat natural gas firing and if the ULTRA conversion system's NOx is a significant quantity that the SCR reactor catalyst has to remove by reaction with ammonia.

It would also be beneficial to know if the amount of natural gas consumed (million Btu/hr) and NOx produced (lb/mmBtu) by the flue gas reheat natural gas firing ahead of the SCR reactors for what amount of time during system startup is higher than the steady-state rates which are shown in the preliminary PFDs/ mass balances. Our interest is whether this firing has substantially greater rates to shorten the amount of time for ramp-up of the gas temperature into the reactor and subsequent ability to start the boiler coal-firing period. This will help us include this in our economic and BACT analysis studies.

We realize that the design basis of the Fuel Tech ULTRA systems recently provided (by Julie Higgins) with budgetary pricing is slightly different than that for the SCRs' design basis, i.e. slightly higher inlet NOx lb/mmBtu, lower NOx removal percentage. This is acceptable, as we can assume the numbers you provide for the SCRs and know that the ULTRA proposal design basis numbers are slightly higher so we have a conservative approach, i.e. built-in capacity margin above maximum expected demand.

Thanks,

Bob Blakley

Bob,
Attached are the revised PFDs for Unit 1 to reflect the single reactor.
Also attached is the summary of data you requested last Thursday.

At this time, we have not estimated the natural gas consumption during startup. This is in part a function of the GGH design and the specific startup procedure. Volker and I will discuss and see if we can provide some context.

Please let us know if we can clarify anything.
Best Regards,
Bob

Bob -

We have discovered several inconsistencies that we need you to confirm and/or clarify, as noted in the email below. I have not independently verified the natural gas heat inputs for the flue gas reheating that Zac has provided in the tables for Unit 2 from September 11th PFDs. My numbers below are different for Unit 2 "differential heat" gas consumption inputs.

We also note that the updated flue gas reheat mMMBtu/hr numbers provided in the summary table included in your 9/22/09 email do not match the values shown on the individual process flow diagrams and preliminary mass balance calculations:

		Unit 1 Low Dust	Unit 1 Tail End	Unit 2 Low Dust	U Tai
Reheat Natural Gas	MMBtu/hr	30	33	43.1	4

9/22 PFD	MM Btu/hr	31.1	60.3		
9/11 PFD	MM Btu/hr			48.1	50.8

Please review and let us know promptly with your findings and any corrections needed. We are trying to wrap this up for submittal to Minnkota next week.

Bob Blakley

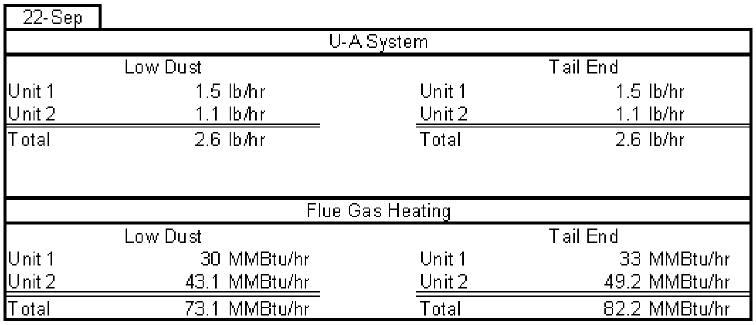
Subject: RE: 22Sep_MRYS Additional Data & Revised PFDs

Bob,
There are some additional discrepancies in the documents attached. The NG and Urea rates are now different between the Unit 1 Low Dust and Tail End options. The NG and Urea flow rates for the U1 Tail End case is 180 and 1970 lb/hr respectively. The NG and Urea flow rates for the U1 Low Dust case is 190 and 2081 lb/hr respectively. The rates for both U1 options should be the same. The U1 Tail End case is the same as previous PFD's so I would assume that the Low Dust case is incorrect.

Also, NG usage rates presented in the Additional Mass Balance Data table are different than what was shown in the previous PFD's. See the comparison below. The lb/hr rates look very odd and the lb/MMbtu rates are different that the previous PFD's.



22-Sep

U-A System			
Low Dust		Tail End	
Unit 1	1.5 lb/hr	Unit 1	1.5 lb/hr
Unit 2	1.1 lb/hr	Unit 2	1.1 lb/hr
Total	2.6 lb/hr	Total	2.6 lb/hr

All -

Here are the updated preliminary process flow diagrams with abbreviated mass balance calculations of Unit 1.
Unit 2's updates were previously provided on Sept. 11.

Please advise if additional information is desired.

Subject: 22Sep_MRYS Additional Data & Revised PFDs

Bob,
Attached are the revised PFDs for Unit 1 to reflect the single reactor.
Also attached is the summary of data you requested last Thursday.

At this time, we have not estimated the natural gas consumption during startup. This is in part a function of the GGH design and the specific startup procedure. Volker and I will discuss and see if we can provide some context.

Please let us know if we can clarify anything.
Best Regards,
Bob

Subject: RE: [aregc] SCR Maintenance

Stu

I will try to give you some answers to your questions although as you are aware, in this business there are so many variables that affect the outcome, it is difficult come up with some absolutes.

1) cool-down of the SCR; Depending upon the outside air temperature and specific operating procedures which should open all dampers, doors and continuous operation of the fans, we typically see 36 to 48 hrs before entering the SCR.

(2) removal of the catalyst including time to scaffold, and vacuum ash prior to catalyst removal; This is dependent upon the your design, humidity, your operation of the sonic horns and pitch of your chosen catalyst. We have seen anything from a shift to several days to perform the vacuuming. Scaffolding is minimal and is installed in less than a shift.

(3) replacement of the catalyst including time to remove scaffolding, planking and re-seal the reactor; Typical removal on and replacement on units in the 500-650MW size has been accomplished in approximately 1 week per layer of catalyst, separate SCR boxes can accommodate simultaneous work but we typically don't have people working on top of each other. This is dependent upon the type of catalyst, number of blocks, design which should include permanent monorails for every layer and sufficient hoisting equipment.

(4) total time elapsed from shutdown of ammonia feed to restart of
Ammonia - I'm sorry but at this time, I do not have any information to share on this item.

Hopefully this helps.

Sincerely

Dean M. Andrisevic

Stu,

I don't know if you have requested support from anyone within the Babcock & Wilcox Construction organization, but they should be very qualified to answer your questions regarding SCR demo and installation.

I have copied several individuals within the B&W Co. that should be able to provide you the information you need.

Good luck.

Subject: [aregc] SCR Maintenance

Hi, Everyone,

On September 2, 2009, I sent out a request for information regarding SCR maintenance. I did receive some responses and I greatly appreciate it. However, it appears that I lacked specificity in my question. Therefore, I am once again appealing to you for additional information. I will be grateful for any help you can give me by responding to the questions below. Thanks all.

We are investigating the requirements for a possible SCR retrofit at Milton R. Young Station. We need to assess the time required to change out a layer of catalyst in an SCR for cases in which there is not a planned maintenance outage available. We need to know how long we can expect the unit to be down. We are looking for actual experience as to the time required for the following steps in this process:
(1) cool-down of the SCR;
(2) removal of the catalyst including time to scaffold, and vacuum ash prior to catalyst removal;
(3) replacement of the catalyst including time to remove scaffolding, planking and re-seal the reactor;
(4) total time elapsed from shutdown of ammonia feed to restart of ammonia feed. For comparison purposes, please indicate the number of catalyst modules involved in your case.

Please indicate the number of shifts and shift length or total elapsed time hours for each step (1-4) above. Please also indicate the time required to stage for the change-out assuming the change-out occurs as a non-planned activity.

Bob -

As we discussed, please check the total gas mass flow numbers in the PFDs versus the sum of the values copied from the spreadsheet as they do not match for any of the four cases:
> 9/11 U2 TE & LD SCRs
> 9/22 U1 LD SCR and 9/24 U1 TE SCR.

Also, in these PFDs, the urea mass flow and ULTRA system natural gas heat input for the Unit 1 low dust SCR are not the same as the Unit 1 tail end SCR, which we believe should match.
The revised summary table also shows two different values for the ULTRA system natural gas flows for Unit 1. Unit 2's ULTRA numbers are matching.

We appreciate your help in getting this corrected and back to us on Monday, 9/28.

Bob,

Attached are the revised PFDs.

I added a summary line to the mass balance table, and all of the flows match those on the flow diagram.

The balance around the ULTRA system for the U1 systems has been corrected.

Please let us know if we can clarify anything.

Best Regards, Bob

Wayne,

Attached is some information on the increase in sulfation rates of small fly ash particles (less than 5 microns) with and without catalyst.

Let me know if you have questions.

Steve

Extracted from past report “Ash Impacts on SCR Performance, S. Benson, 2005.”

Tests of fly ash sulfation were conducted using a thermogravimetric analyzer (TGA). TGA testing was conducted using a <5-µm-size fraction of ash produced from Powder River Basin (PRB) coals and lignites and exposing them to vapor-phase sulfur dioxide with and without catalyst at several temperatures. The aim of the testing was to determine the potential of the formation of sulfates to cause particle-to-particle bonding that leads to the formation of deposits in the temperature range where SCR catalysts are used. The TGA testing is focused on determining the reactivity of the <5-µm ash produced from selected PRB and blends to sulfur dioxide and gas-phase phosphorus species as a function of temperature. Testing was conducted to determine the weight gain with flue gas containing ammonia. The impact temperature on the weight gain due to the formation of sulfates for a PRB blend is shown in Figure 8. The rates of sulfation were found to increase with increased temperature. The results show an increase in the weight gains when ammonia and phosphorus were added. Ground catalyst was mixed with PRB and placed in the TGA. Increases in weight gain were observed when catalyst was added as compared to baseline cases for 100% PRB, as shown in Figures 8 and 9, respectively. The presence of catalyst enhances the formation of sulfates.

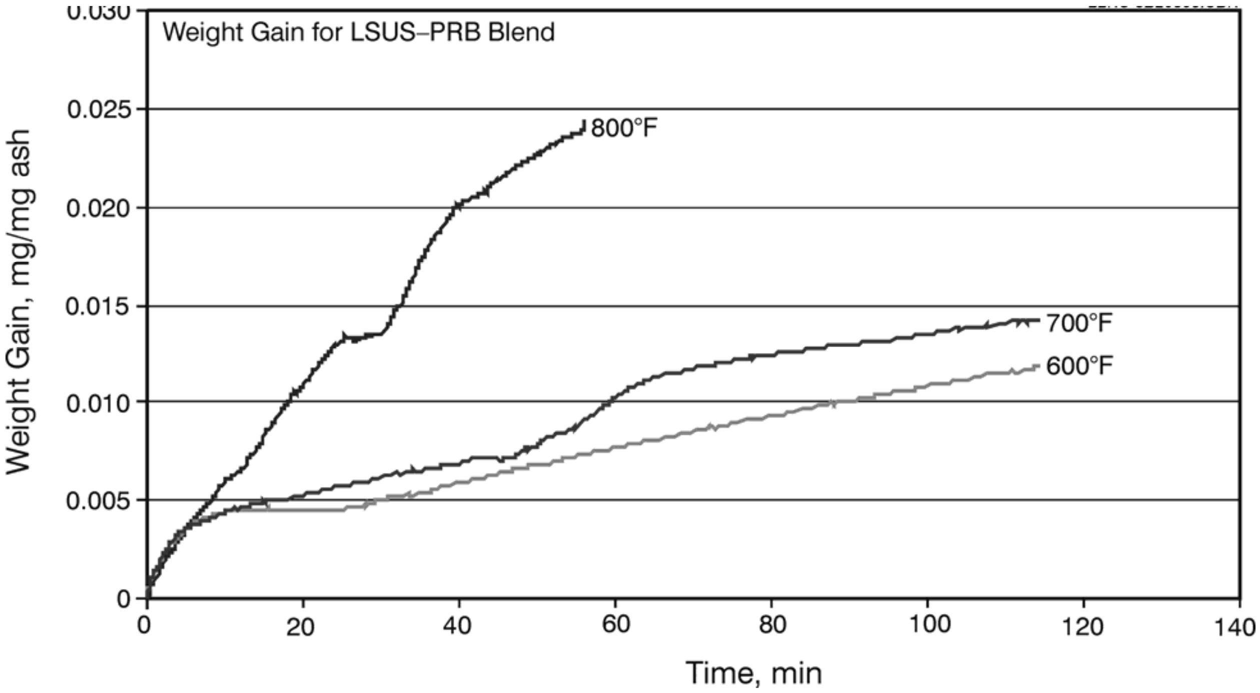

Figure 8. Weight changes for PRB-blend coal ash exposed to flue gases and ammonia at three temperatures.

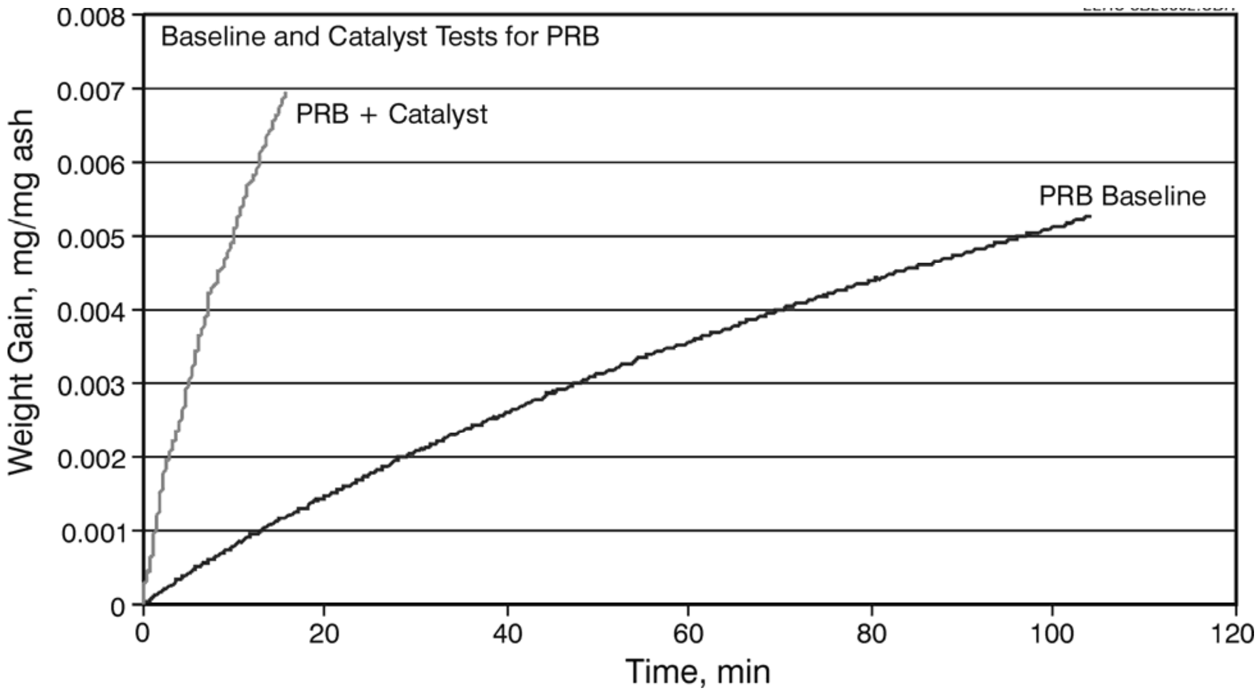

Figure 9. Weight changes for PRB-blend coal ash exposed to flue gases and ammonia with and without SCR catalyst present.

Ron,

I got a response back today from Denmark with answers to some of the questions posed during our conference call earlier this week.

Amager, has not started up so we have no data concerning SCR operation. They seem to be having problems with the boiler and FGD systems and that has prevented any significant run time.

Also, an issue came up yesterday requiring me to travel today. I had planned to finish the proposal today but I don't think that will be possible. I will work on it this weekend and have it you as early on Monday as possible.

Thanks,
Wayne

Bob -

Carl Weilert and I reviewed information involving hypothetical applications of tail end and low dust SCR technologies at Minnkota's Milton R. Young Station with the North Dakota Department of Health's Air Quality Division on Monday, December 21, 2009.

Estimated Natural Gas Consumption for Reheating Flue Gas:

> Unit 1 Low Dust SCR System	31 MMBtu/hr
> Unit 1 Tail End SCR System	60.3 MMBtu/hr
> Unit 2 Low Dust SCR System	96.2 MMBtu/hr
> Unit 2 Tail End SCR System	101.6 MMBtu/hr

Estimated Natural Gas Consumption for Urea to Ammonia Conversion:

> Unit 1 SCR System	4.3 MMBtu/hr
> Unit 2 SCR System	6.7 MMBtu/hr

The NDDH technical lead person wanted to know if Unit 2's low dust gas for reheat was correct, as it appears to be much closer to the natural gas consumption for tail end than when comparing Unit 1's LD to TESCR natural gas numbers. We told him we also noticed this difference in proportion but didn't know what numbers may be in need of revision.

We ask that you review the preliminary process design numbers for reheat fuel (and Ultra system fuel) in all four SCR cases by January 7th, so we can respond back to the NDDH on this issue, as it affects the cost effectiveness analysis for these alternatives in the updated BACT studies.

Hope you are getting a change to enjoy time with your families this holiday season.

Merry Christmas.

Bob,
Attached are the revised PFDs.
I added a summary line to the mass balance table, and all of the flows match those on the flow diagram.
The balance around the ULTRA system for the U1 systems has been corrected.

Please let us know if we can clarify anything.
Best Regards, Bob

Wayne:

Confirming my voice mail message of January 6, 2010. Please call me when you have a chance.

We are asking for review of our attached letter with written confirmation regarding stating Haldor Topsoe's catalyst life guarantee being contingent upon successful completion of pilot-scale slipstream testing that confirm catalyst deactivation and fouling rates of the studied hypothetical applications of tail end and low-dust SCRs for Units 1 and 2 at Milton R. Young Station for Minnkota Power Cooperative.

Minnkota Power Cooperative Milton R. Young Station Units 1 & 2
Investigation of Hypothetical Application of TESCR and LDSCR
BMcD Project 31777

Dear Mr. Jones:

Burns & McDonnell has prepared supplemental reports for the NOx BACT analyses for Milton R. Young Station (MRYS) Units 1 and 2, and these reports have been submitted by Minnkota Power Cooperative to the North Dakota Department of Health. In the text of these reports, we stated that:

> During preparation of the cost estimate, Burns & McDonnell consulted with two SCR catalyst vendors experienced with biomass-fired boiler SCRs and European coal-fired boilers with low-dust and tail end SCR systems. However, neither of these vendors was willing to guarantee a catalyst replacement schedule for cyclone boilers firing North Dakota lignite without results following successful extensive pilot-scale slipstream testing that confirm the deactivation and fouling rates. According to these catalyst suppliers, there is no SCR operating experience in the world found to be directly comparable to the hypothetically applied tail end and low-dust SCR cases on North Dakota lignite-fired cyclone boilers being evaluated. Thus they were unable to offer a guaranteed catalyst replacement schedule based on their experience.

Please review this statement and respond in writing to confirm that we have correctly stated your company's position on catalyst life guarantees for the application of SCR systems to MRYS Units 1 & 2 without successful completion of pilot testing.

Sincerely,

Robert D. Blakley

Volker -

I am resending this email from 12/22, seeking your assistance in confirming the natural gas consumption rates for all four cases studied (see below and attached).

We are now on a tight timeline for response back to Minnkota for providing the correct numbers and any revised BACT Analysis ($ per ton) so they can respond the the State of North Dakota's Health Department - Air Quality Division.

Please advise you can confirm the process design as regards natural gas rates by 1/15/10.

Thanks,

Robert D. Blakley, P.E.

Bob -

Carl Weilert and I reviewed information involving hypothetical applications of tail end and low dust SCR technologies at Minnkota's Milton R. Young Station with the North Dakota Department of Health's Air Quality Division on Monday, December 21, 2009.

Estimated Natural Gas Consumption for Reheating Flue Gas:

> Unit 1 Low Dust SCR System	31 MMBtu/hr
> Unit 1 Tail End SCR System	60.3 MMBtu/hr
> Unit 2 Low Dust SCR System	96.2 MMBtu/hr

> Unit 2 Tail End SCR System 101.6 MMBtu/hr

Estimated Natural Gas Consumption for Urea to Ammonia Conversion:
> Unit 1 SCR System 4.3 MMBtu/hr
> Unit 2 SCR System 6.7 MMBtu/hr

The NDDH technical lead person wanted to know if Unit 2's low dust gas for reheat was correct, as it appears to be much closer to the natural gas consumption for tail end than when comparing Unit 1's LD to TESCR natural gas numbers. We told him we also noticed this difference in proportion but didn't know what numbers may be in need of revision.

We ask that you review the preliminary process design numbers for reheat fuel (and Ultra system fuel) in all four SCR cases by January 7th, so we can respond back to the NDDH on this issue, as it affects the cost effectiveness analysis for these alternatives in the updated BACT studies.

Hope you are getting a change to enjoy time with your families this holiday season.

Merry Christmas.

Bob Blakley

Subject: 28Sep_PFD Revisions

Bob,
Attached are the revised PFDs.
I added a summary line to the mass balance table, and all of the flows match those on the flow diagram.
The balance around the ULTRA system for the U1 systems has been corrected.
Please let us know if we can clarify anything.
Best Regards, Bob

Robert,

CERAM confirms that the attached letter accurately reflects our position regarding catalyst life guarantees for the Milton R. Young Station tail end and low-dust SCR applications.

Best regards,

Noel Rosha, P.E.

Minnkota Power Cooperative Milton R. Young Station Units 1 & 2
Investigation of Hypothetical Application of TESCR and LDSCR
BMcD Project 31777

Dear Mr. Rosha:

Burns & McDonnell has prepared supplemental reports for the NOx BACT analyses for Milton R. Young Station (MRYS) Units 1 and 2, and these reports have been submitted by Minnkota Power Cooperative to the North Dakota Department of Health. In the text of these reports, we stated that:

> During preparation of the cost estimate, Burns & McDonnell consulted with two SCR catalyst vendors experienced with biomass-fired boiler SCRs and European coal-fired boilers with low-dust and tail end SCR systems. However, neither of these vendors was willing to guarantee a catalyst replacement schedule for cyclone boilers firing North Dakota lignite without results following successful extensive pilot-scale slipstream testing that confirm the deactivation and fouling rates. According to these catalyst suppliers, there is no SCR operating experience in the world found to be directly comparable to the hypothetically applied tail end and low-dust SCR cases on North Dakota lignite-fired cyclone boilers being evaluated. Thus they were unable to offer a guaranteed catalyst replacement schedule based on their experience.

Please review this statement and respond in writing to confirm that we have correctly stated your company's position on catalyst life guarantees for the application of SCR systems to MRYS Units 1 & 2 without successful completion of pilot testing.

Sincerely,

Robert D. Blakley

Investigation of Hypothetical Application of TESCR and LDSCR
BMcD project 31777

Mr. Blakley,

This letter is to confirm that it is my understanding, based on the information currently at hand, that Haldor Topsoe, Inc would consider providing a SCR catalyst life guarantee for either Milton R. Young Unit 1 or Unit 2 for either a tail end (TESCR) or low dust (LDSCR) configuration only following the successful completion of a pilot-scale slipstream test of our SCR catalyst on one of the two MRY units. The issuance of a SCR catalyst life guarantee, if any, would be for only the configuration tested during the pilot-scale testing.

If you have any question please feel free to contact me at 281-228-5136

Dear Bob,

Both Bob Johnson and I reviewed the calculations and I would like to confirm that we did not find any error. The only adjustment will come once to get the final GGH design, since this is an iterative process. The changes will be minor and the same for all options, the ratio between the options will not change.

Best regards,

Volker

Volker -

I am resending this email from 12/22, seeking your assistance in confirming the natural gas consumption rates for all four cases studied (see below and attached).

We are now on a tight timeline for response back to Minnkota for providing the correct numbers and any revised BACT Analysis ($ per ton) so they can respond the the State of North Dakota's Health Department - Air Quality Division.

Please advise you can confirm the process design as regards natural gas rates by 1/15/10.

Thanks,

Robert D. Blakley, P.E.

Subject: FW: 28Sep_PFD Revisions

Bob -

Carl Weilert and I reviewed information involving hypothetical applications of tail end and low dust SCR technologies at Minnkota's Milton R. Young Station with the North Dakota Department of Health's Air Quality Division on Monday, December 21, 2009.

Estimated Natural Gas Consumption for Reheating Flue Gas:

> Unit 1 Low Dust SCR System	31 MMBtu/hr
> Unit 1 Tail End SCR System	60.3 MMBtu/hr
> Unit 2 Low Dust SCR System	96.2 MMBtu/hr
> Unit 2 Tail End SCR System	101.6 MMBtu/hr

Estimated Natural Gas Consumption for Urea to Ammonia Conversion:

> Unit 1 SCR System	4.3 MMBtu/hr
> Unit 2 SCR System	6.7 MMBtu/hr

The NDDH technical lead person wanted to know if Unit 2's low dust gas for reheat was correct, as it appears to be much closer to the natural gas consumption for tail end than when comparing Unit 1's LD to TESCR natural gas numbers. We told him we also noticed this difference in proportion but didn't know what numbers may be in need of revision.

We ask that you review the preliminary process design numbers for reheat fuel (and Ultra system fuel) in all four SCR cases by January 7th, so we can respond back to the NDDH on this issue, as it affects the cost effectiveness analysis for these alternatives in the updated BACT studies.

Hope you are getting a change to enjoy time with your families this holiday season.

Merry Christmas.

Subject: 28Sep_PFD Revisions

Bob,
Attached are the revised PFDs.
I added a summary line to the mass balance table, and all of the flows match those on the flow diagram.
The balance around the ULTRA system for the U1 systems has been corrected.
Please let us know if we can clarify anything.
Best Regards, Bob

AIR POLLUTION CONTROL
PERMIT TO CONSTRUCT
FOR
BEST AVAILABLE RETROFIT TECHNOLOGY (BART)

Pursuant to the Air Pollution Control Rules of the State of North Dakota (North Dakota Administrative Code Article 33-15, Chapter 33-15-14 and Chapter 33-15-25), the North Dakota Department of Health hereby grants a Permit to Construct for the following BART source:

I. **General Information**:

A. **Permit to Construct Number**: TBD

B. **Source**:

1. **Name**: Leland Olds Station

2. **Location**: Stanton, North Dakota, Mercer County

3. **Source Type**: Fossil-fuel fired steam electric plant with a nominal generating capacity of 656 megawatts.

4. **Equipment at the Facility Subject to BART**:

Unit 1 - Coal-fired boiler (nominal 2622 x 10^6 Btu/hour heat input)

Unit 2 - Coal-fired boiler (nominal 5130 x 10^6 Btu/hour heat input)

C. **Owner/Operator**:

1. **Name**: Basin Electric Power Coop.

2. **Address**:
1717 E Interstate Avenue
Bismarck, ND 58501-0564

II. **Permit Conditions**:

The Permit to Construct only establishes the BART emission limits if, and when, EPA approves those limits as part of the Regional Haze SIP. This permit allows the construction and initial operation of new or modified air pollution control equipment and process modifications at the source to comply with the BART limits. If new emission units are created, a new Permit to Construct may be required in accordance with NDAC 33-15-14-02. The source shall be operated in accordance with the terms of this Permit to Construct and the Title V Permit to Operate until a revised Title V Permit to Operate is issued. The source is subject to all applicable rules, regulations, and orders now or hereafter in effect of the North Dakota Department of Health and to the conditions specified below:

A. **Special Conditions**:

1. **Emission Limits**: The term "30-day rolling average," as used in this permit, shall be determined by calculating an arithmetic average of all hourly rates for the current boiler operating day and the previous 29 boiler operating days. A new 30-day rolling average shall be calculated for each boiler operating day. Each 30-day rolling average rate shall include start-up, shutdown, emergency and malfunction periods unless those periods are exempt by this permit. The 30-day rolling average emission rate is calculated as follows:

- Calculate the hourly average emission rate for any hour in which any fuel is combusted in the boiler.

- Calculate the daily average emission rate from the hourly average emission rates for that boiler operating day.

- Calculate the 30-day rolling average emission rate from the daily average emission rate for the current boiler operating day and the daily average emission rate for the previous 29 boiler operating days.

The term "boiler operating day," as used in this permit, means any twenty-four-hour period between midnight and the following midnight during which any fuel is combusted at any time at the steam generating unit.

a. Basin Electric shall not discharge or cause the discharge of sulfur dioxide (SO_2) into the atmosphere from Unit 1 and Unit 2 in excess of either:

(1) 0.15 pounds per million British thermal units ($lb/10^6$ Btu) of heat input on a 30-day rolling average basis;

or as an alternative

(2) 5.0% of the SO_2 reaching the inlet of the scrubber (95.0% reduction) on a 30-day rolling average basis.

For determining compliance with the above emission limits, Basin Electric may average emissions from Unit 1 and Unit 2 provided the average does not exceed 0.15 $lb/10^6$ Btu; or 5.0 percent (95.0% reduction) of the SO_2 reaching the inlet of the scrubbing system(s), as appropriate.

b. Basin Electric shall not discharge or cause the discharge of nitrogen oxides (NO_x) into the atmosphere from Unit 1 in excess of 0.19 pounds per million British thermal units ($lb/10^6$ Btu) of heat input, on a 30-day rolling average basis.

Basin Electric shall not discharge or cause the discharge of nitrogen oxides (NO_x) into the atmosphere from Unit 2 in excess of 0.35 pounds per million British thermal units ($lb/10^6$ Btu) of heat input, on a 30-day rolling average basis.

For determining compliance with the above emission limits, Basin Electric may average emissions from Unit 1 and Unit 2 provided the actual average emission rate does not exceed the average allowable emission rate calculated in accordance with Condition II.A(4)(b)(8).

c. Basin Electric shall not discharge or cause the discharge of filterable (non-condensible) particulate matter (PM) into the atmosphere in excess of the following:

Unit 1 - 0.07 lb/10^6 Btu
Unit 2 - 0.07 lb/10^6 Btu

Compliance with the limits is determined in accordance with the procedures in Condition II.A.4.b.5.

d. The emission limits apply at all times including startup, shutdown, emergency and malfunction.

2. **Compliance Date**: Compliance with the emission limits and other requirements of this permit is required as expeditiously as practicable but in no event later than five years after the U.S. Environmental Protection Agency approves this permit as a part of the Regional Haze SIP. Compliance shall be demonstrated within 180 days of initial startup of the equipment required to meet the BART limits, but no later than 5 years after the U.S. Environmental Protection Agency approves this permit as a part of the BART SIP.

3. **Continuous Emission Monitoring (CEM)**: The emissions from Unit 1 (main stack) and Unit 2 (main stack) shall each be measured by continuous emission monitors (CEM) for SO_2, NO_x, CO_2, and flow. The monitoring requirements under Condition II.A.4 shall be the compliance determination method for SO_2 and NO_x.

4. **Monitoring Requirements and Conditions**:

a. Requirements:

Basin Electric is only required to monitor compliance with one SO_2 limit (i.e., either the lb/10^6 Btu limit or the 95% reduction limit). If Basin Electric monitors for both limits, and compliance is indicated for one limit but not the other, no excess emissions or monitoring deviations shall be reported with respect to the other limit.

Testing and monitoring protocols used to demonstrate compliance with the emission limits of Condition II.A.1 above shall be as follows:

Pollutant/ Parameter	**Monitoring Requirement (Method)**	**Condition Number**
Particulate	Compliance Assurance Monitoring (CAM)/	4.b.(6)/4.b.(5)

Pollutant/ Parameter	**Monitoring Requirement (Method)**	**Condition Number**
	Emissions Test	
SO_2 (inlet)	CEM; or Coal Sampling Data & Emission Factor[a]	4.b.(1), 4.b.(2), 4.b.(3), 4.b.(7), & 4.b.(8)
SO_2 (outlet)	CEM	
NO_x	CEM	4.b.(1), 4.b.(2), 4.b.(3), & 4.b.(8)
CO_2	CEM	4.b.(1), 4.b.(2), & 4.b.(3)
Flow	Flow Monitor	4.b.(1), 4.b.(2), & 4.b.(3)

[a] Emission factor refers to the value (e.g. percentage of inlet sulfur leaving the boiler), that is determined by stack testing, which is used to calculate the scrubber SO_2 inlet rate.

b. Emission Monitoring Conditions:

(1) The monitoring shall be in accordance with the following applicable requirements of Chapter 33-15-06 of the North Dakota Air Pollution Control Rules and the Acid Rain Program. Emissions are calculated using 40 CFR Part 75.

(a) Section 33-15-06-04 of the North Dakota Air Pollution Control Rules, Monitoring Requirements.

(b) 40 CFR 72 and 40 CFR 75.

(2) The Department may require additional performance audits of the CEM systems.

(3) When a failure of a continuous emission monitoring system occurs, an alternative method, acceptable to the Department, for measuring or estimating emissions must be undertaken as soon as possible. The procedures outlined in 40 CFR 75, Subpart D for substitution are considered an acceptable method for the emission rate limit. The procedures of Method 19, Paragraph 12.7, are considered an acceptable method for the percent reduction requirement. Timely repair of the emission monitoring system must be made.

(4) Basin Electric shall maintain and operate air pollution control monitoring equipment in a manner consistent the manufacturer’s recommended Operations and Maintenance (O&M) procedures, or a site-specific O&M procedure (developed from the manufacturer’s recommended O&M procedures). Basin Electric shall have the O&M procedures available on-site and provide the Department with a copy when requested.

(5) Within 180 days of initial startup of the equipment required to meet the BART limits, but not later than 5 years after approval of the Regional Haze SIP by the U.S. Environmental Protection Agency, Basin Electric shall conduct an emissions test to measure particulate emissions, using EPA Test Method 5B or Method 17 in 40 CFR Part 60, Appendix A. A test shall consist of three runs, with each run at least 120 minutes in duration and each run collecting a minimum sample of 60 dry standard cubic feet. Other EPA approved test methods may be used provided they are approved, in advance, by the Department.

(6) Monitoring for particulate matter shall be conducted in accordance with the Compliance Assurance Monitoring (CAM) Plan developed in accordance with NDAC 33-15-14-06.10. The CAM plan revision to address the BART PM limit shall be submitted with the Title V permit revision application for the BART limits.

(7) In lieu of using a continuous emission monitor to determine the SO_2 reaching the scrubber inlet(s) in accordance with Condition II.A.1.a., Basin Electric may use coal sampling and an emission factor established by stack testing. The requirements in 40 CFR 60, Appendix A, Method 19 shall be used to determine coal sampling and analysis requirements.

For purposes of determining compliance with the SO_2 percent reduction requirement, the reduction efficiency shall be determined as follows:

$$\%\ \text{Reduction} = \frac{\text{Inlet } SO_2 \text{ Rate} - \text{Outlet } SO_2 \text{ Rate}}{\text{Inlet } SO_2 \text{ Rate}} \times 100$$

Where: The Inlet SO_2 Rate is in units of $lb/10^6$ Btu, lb/hr, or ppmvd @ 3% O_2 and the Outlet SO_2 Rate is in the same units as the Inlet SO_2 Rate.

(8) When averaging the emissions of Unit 1 and Unit 2, compliance shall be determined in accordance with the following:

$$\text{Average AER} = \frac{[(AER_1)(HI_1)+(AER_2)(HI_2)]}{(HI_1 + HI_2)}$$

$$\text{Average ER} = \frac{[(ER_1)(HI_1)+(ER_2)(HI_2)]}{(HI_1 + HI_2)}$$

AER = Allowable Emission Rate (lb/MMBtu or % Reduction)
Average ER = Average Actual Emission Rate
ER_1 = Actual Emission Rate (lb/MMBtu or % Reduction) of Unit 1

ER_2 = Actual Emission Rate (lb/MMBtu or % Reduction) of Unit 2
HI_1 = Actual Heat Input (MMBtu) of Unit 1
HI_2 = Actual Heat Input (MMBtu) of Unit 2

Notes:
- ER and HI are 30-day rolling averages.
- 30-day rolling average for the 30 successive boiler operating days as defined in Condition II.A.1.
- % Reduction can be on either a lb/10^6 Btu, ppmvd @ 3% O_2, or pounds of SO_2 basis.

5. **Recordkeeping Requirements**:

a. Basin Electric shall maintain compliance monitoring records for Unit 1 and Unit 2 as outlined in Table 1 Monitoring Records, that includes the following information:

(1) The date, place (as defined in the permit) and time of sampling or measurement.

(2) The date(s) testing was performed.

(3) The company, entity, or person that performed the testing.

(4) The testing techniques or methods used.

(5) The results of such testing.

(6) The unit load that existed at the time of sampling or measurement.

(7) The records of quality assurance for emissions measuring systems including but not limited to quality control activities, audits and calibration drifts as required by the applicable test method.

(8) A copy of all field data sheets from the emissions testing.

(9) A record shall be kept of all major maintenance activities conducted on the emission units or air pollution control equipment.

(10) Records shall be kept as to the type of fuel usage.

Table 1 Monitoring Records

Pollutant/Parameter	Compliance Monitoring Record
Particulate	CAM Data & Emissions Test Data

Pollutant/Parameter	Compliance Monitoring Record
SO_2 outlet (lb/10^6 Btu)	CEM Data
SO_2 inlet (% Reduction)	CEM Data; or Coal Sampling Data & Emission Factor for Inlet SO_2 Rate
SO_2 outlet (% reduction)	CEM Data
NO_x	CEM Data
CO_2	CEM Data
Flow	Flow Monitor Data

b. In addition to requirements outlined in Condition II.5.a., recordkeeping for Unit 1 and Unit 2 shall be in accordance with the following applicable requirements of Chapter 33-15-06 and Chapter 33-15-14 of the North Dakota Air Pollution Control Rules and the Acid Rain Program:

(1) Section 33-15-06-05 of the North Dakota Air Pollution Control Rules, Reporting and Recordkeeping Requirements.

(2) 40 CFR 72 and 40 CFR 75.

(3) 40 CFR Part 64, Section 64.9 - Reporting and Recordkeeping Requirements, Paragraph (b) General Recordkeeping Requirements.

c. Basin Electric shall retain records of all required compliance monitoring data and support information for a period of at least five years from the date of the compliance monitoring sampling, measurement, report, or application. Support information includes all maintenance records of the emission units and all original strip-chart recordings/computer printouts and calibrations of the continuous compliance monitoring instrumentation, and copies of all reports required by the permit.

6. **Reporting**:

a. For Unit 1 and Unit 2, reporting shall be in accordance with the following applicable requirements of Chapter 33-15-06 and Chapter 33-15-14 of the North Dakota Air Pollution Control Rules and the Acid Rain Program.

(1) Section 33-15-06-05 of the North Dakota Air Pollution Control Rules, Reporting and Recordkeeping Requirements.

(2) 40 CFR 72 and 40 CFR 75.

(3) 40 CFR Part 64, Section 64.9 - Reporting and Recordkeeping Requirements, Paragraph (a) General Reporting Requirements.

(4) Quarterly excess emissions reports for Unit 1 and Unit 2 shall be submitted no later than the 30th day following the end of each calendar quarter. Excess emissions are defined as emissions which exceed the emission limits for Unit 1 and Unit 2 as outlined in Condition II.A.1. Data regarding only one of the two SO_2 limits must be included in the excess emissions report. Excess emissions shall be reported for the following:

Parameter	Reporting Period
SO_2 lb/10^6 Btu or percent reduction	(30-day rolling average)
NO_x lb/10^6 Btu	(30-day rolling average)

b. Basin Electric shall submit a semi-annual report for all monitoring records required under Condition II.A.5 on forms supplied or approved by the Department. All instances of deviations from the permit must be identified in the report. A monitoring report shall be submitted within 45 days after June 30 and December 31 of each year.

c. Basin Electric shall submit an annual compliance certification report within 45 days after December 31 of each year on forms supplied or approved by the Department.

d. For emission units where the method of compliance monitoring is demonstrated by either an EPA Test Method or portable analyzer, the test report shall be submitted to the Department within 60 days after completion of the test.

e. Basin Electric shall submit an annual emission inventory report on forms supplied or approved by the Department. This report shall be submitted by March 15 of each calendar year. Insignificant units/activities listed in this permit do not need to be included in the annual emission inventory report.

f. Basin Electric shall submit to the Department written semi-annual reports detailing progress toward completion of the requirements of this permit. The semi-annual reports shall be due no later than 45 days after June 30 and December 31 of each year. The first report shall be due following the end of the first complete semi-annual period after the permit is issued.

g. Basin Electric shall notify the Department of the actual startup date of the equipment required to meet the BART limits.

B. **General Conditions**:

1. This permit shall in no way permit or authorize the maintenance of a public nuisance or danger to public health or safety.

2. Basin Electric shall comply with all State and Federal environmental laws and rules. In addition, Basin Electric shall comply with all local building, fire, zoning, and other applicable ordinances, codes, rules and regulations.

3. All reasonable precautions shall be taken by Basin Electric to prevent and/or minimize fugitive emissions during the construction period.

4. Basin Electric shall at all times, including periods of startup, shutdown, and malfunction, maintain and operate Unit 1 and Unit 2 and all other emission units including associated air pollution equipment and fugitive dust suppression operations in a manner consistent with good air pollution control practices for minimizing emissions.

5. Any duly authorized officer, employee or agent of the North Dakota Department of Health may enter and inspect any property, premise or place at which the source listed in Item I.B. of this permit is or will be located at any time for the purpose of ascertaining the state of compliance with the North Dakota Air Pollution Control Rules and the conditions of this permit.

6. Any violation of a condition issued as part of this approval to construct is regarded as a violation of construction authority and is subject to enforcement action.

7. The conditions of this permit herein become, upon the effective date of this permit, enforceable by the Department pursuant to any remedies it now has or may in the future have, under the North Dakota Air Pollution Control Law, NDCC Chapter 23-25. Each and every condition of this permit is a material part thereof, and is not severable.

AIR POLLUTION CONTROL
PERMIT TO CONSTRUCT
FOR
BEST AVAILABLE RETROFIT TECHNOLOGY (BART)

Pursuant to the Air Pollution Control Rules of the State of North Dakota (North Dakota Administrative Code Article 33-15, Chapter 33-15-14 and Chapter 33-15-25), the North Dakota Department of Health hereby grants a Permit to Construct for the following BART source:

I. General Information:

A. **Permit to Construct Number**: TBD

B. **Source**:

1. **Name**: Coal Creek Station

2. **Location**: Sections 8, 9, 16, 17, T145N, R82W, McLean County, North Dakota

3. **Source Type**: Fossil-fuel fired steam electric plant with a nominal generating capacity of 1,100 megawatts.

4. **Equipment at the Facility Subject to BART**:

Unit 1 -Lignite-fired boiler (nominal 6015 x 10^6 Btu/hour heat input)

Unit 2 -Lignite-fired boiler (nominal 6022 x 10^6 Btu/hour heat input)

C. **Owner/Operator**:

1. **Name**: Great River Energy

2. **Address**:
12300 Elm Creek Boulevard
Maple Grove, MN 55369-4718

II. Permit Conditions:

The Permit to Construct only establishes the BART emission limits if, and when, EPA approves those limits as a part of the Regional Haze SIP. This permit allows the construction and initial operation of new or modified air pollution control equipment and process modifications at the source to comply with the BART limits. If new emission units are created, then a new Permit to Construct may be required in accordance with NDAC 33-15-14-02. The source shall be operated in accordance with the terms of this Permit to Construct and the Title V Permit to Operate until a revised Title V Permit to Operate is issued. The source is subject to all applicable rules, regulations, and orders now or hereafter in effect of the North Dakota Department of Health and to the conditions specified below:

A. **Special Conditions**:

1. **Emission Limits**: The term “30-day rolling average”, as used in this permit, shall be determined by calculating an arithmetic average of all hourly rates for the current boiler operating day and the previous 29 boiler operating days. A new 30-day rolling average shall be calculated for each boiler operating day. Each 30-day rolling average rate shall include start-up, shutdown, emergency and malfunction periods unless those periods are exempt by this permit. The 30-day rolling average emission rate is calculated as follows:

   - Calculate the hourly average emission rate for any hour in which any fuel is combusted in the boiler.

   - Calculate the daily average emission rate from the hourly average emission rates for that boiler operating day.

   - Calculate the 30-day rolling average emission rate from the daily average emission rate for the current boiler operating day and the daily average emission rate for the previous 29 boiler operating days.

   The term “boiler operating day”, as used in this permit, means any twenty-four-hour period between midnight and the following midnight during which any fuel is combusted at any time at the steam generating unit.

   a. Great River Energy shall not discharge or cause the discharge of sulfur dioxide (SO_2) into the atmosphere from Unit 1 and Unit 2 in excess of either:

      (1) 0.15 pounds per million British thermal units ($lb/10^6$ Btu) of heat input on a 30-day rolling average basis;

      or as an alternative

      (2) 5.0 percent of the SO_2 reaching the scrubber inlet on a 30-day rolling average basis (95.0% reduction).

      Great River Energy may average emissions from Unit 1 and Unit 2 provided the average does not exceed either 0.15 $lb/10^6$ Btu; or 5.0 percent of the SO_2 reaching the inlet of both scrubbers.

   b. Great River Energy shall not discharge or cause the discharge of nitrogen oxides (NO_x) into the atmosphere from Unit 1 and Unit 2 in excess of 0.17 pounds per million British thermal units ($lb/10^6$ Btu) of heat input per unit, on a 30-day rolling average basis.

      Great River Energy may average emissions from Unit 1 and Unit 2 provided the actual average emission rate does not exceed 0.17 pounds per million British Thermal Units ($lb/10^6$ Btu) of heat input on a 30-day rolling average basis.

c. Great River Energy shall not discharge or cause the discharge of filterable (non-condensible) particulate matter (PM) into the atmosphere in excess of the following:

Unit 1 - 0.07 lb/10^6 Btu
Unit 2 - 0.07 lb/10^6 Btu

Compliance with the limit is determined in accordance with the procedures in II.A.4.b.5.

d. The emission limits apply at all times including startup, shutdown, emergency and malfunction.

2. **Compliance Date**: Compliance with the emission limits and other requirements of this permit is required as expeditiously as practicable but in no event later than five years after the U.S. Environmental Protection Agency approves this permit as a part of the Regional Haze SIP. Compliance shall be demonstrated within 180 days of initial startup of the equipment required to meet the BART limits, but no later than five years after the U.S. EPA approves this permit as a part of the Regional Haze SIP.

3. **Continuous Emission Monitoring (CEM)**: The emissions from Unit 1 (main stack) and Unit 2 (main stack) shall each be measured by continuous emission monitors (CEM) for SO_2, NO_x, CO_2, and flow. The monitoring requirements under Condition II.A.4 shall be the compliance determination method for SO_2 and NO_x.

4. **Monitoring Requirements and Conditions**:

a. Requirements:

Great River Energy is only required to monitor compliance with one SO_2 limit (i.e., either the lb/10^6 Btu limit or the 94% reduction limit). If Great River Energy monitors for both limits, and compliance is indicated for one limit but not the other, no excess emissions or monitoring deviations shall be reported with respect to the other limit.

Testing and monitoring protocols used to demonstrate compliance with the emission limits of Condition II.A.1 above shall be as follows:

Pollutant/ Parameter	**Monitoring Requirement (Method)**	**Condition Number**
Particulate	Compliance Assurance Monitoring (CAM)/ Emissions Test	4.b.(6)/4.b.(5)
SO_2 (inlet)	CEM; or Coal Sampling Data & Emission Factor[a]	4.b.(1), 4.b.(2), 4.b.(3), 4.b.(7), & 4.b.(8)

Pollutant/ Parameter	**Monitoring Requirement (Method)**	**Condition Number**
SO_2 (outlet)	CEM	
NO_x	CEM	4.b.(1), 4.b.(2), 4.b.(3), & 4.b.(8)
CO_2	CEM	4.b.(1), 4.b.(2), & 4.b.(3)
Flow	Flow Monitor	4.b.(1), 4.b.(2), & 4.b.(3)

[a] Emission factor refers to the value (e.g. percentage of inlet sulfur leaving the boiler), that is determined by stack testing, which is used to calculate the scrubber SO_2 inlet rate.

b. Emission Monitoring Conditions:

(1) The monitoring shall be in accordance with the following applicable requirements of Chapter 33-15-06 of the North Dakota Air Pollution Control Rules and the Acid Rain Program. Emissions are calculated using 40 CFR 75.

(a) Section 33-15-06-04 of the North Dakota Air Pollution Control Rules, Monitoring Requirements.

(b) 40 CFR 72 and 40 CFR 75.

(2) The Department may require additional performance audits of the CEM systems.

(3) When a failure of a continuous emission monitoring system occurs, an alternative method, acceptable to the Department, for measuring or estimating emissions must be undertaken as soon as possible. The procedures outlined in 40 CFR 75, Subpart D for substitution are considered an acceptable method for the emission rate limit. The procedures of Method 19, Paragraph 12.7, are considered an acceptable method for the percent reduction requirement. Timely repair of the emission monitoring system must be made.

(4) Great River Energy shall maintain and operate air pollution control monitoring equipment in a manner consistent with the manufacturer's recommended Operations and Maintenance (O&M) procedures, or a site-specific O&M procedure (developed from the manufacturer's recommended O&M procedures). Great River Energy shall have the O&M procedures available on-site and provide the Department with a copy when requested.

(5) Within 180 days of initial startup of the equipment required to meet the BART limits, but not later than 5 years after approval of the Regional Haze SIP by the

U.S. Environmental Protection Agency, Great River Energy shall conduct an emissions test to measure particulate emissions, using EPA Test Method 5B or Method 17 in 40 CFR 60, Appendix A. A test shall consist of three runs, with each run at least 120 minutes in duration and each run collecting a minimum sample of 60 dry standard cubic feet. Other EPA approved test methods may be used provided they are approved, in advance, by the Department.

(6) Monitoring for particulate matter shall be conducted in accordance with the Compliance Assurance Monitoring (CAM) Plan developed in accordance with NDAC 33-15-14-06.10. The CAM plan revision to address the BART PM limit shall be submitted with the Title V revision application for the BART limits.

(7) In lieu of using a continuous emission monitor to determine the SO_2 reaching the wet scrubber inlets in accordance with Condition II.A.1.a., Great River Energy may use coal sampling and an emission factor established by stack testing. The requirements in 40 CFR 60, Appendix A, Method 19 shall be used to determine coal sampling and analysis requirements.

For purposes of determining compliance with the SO_2 percent reduction requirement, the reduction efficiency shall be determined as follows:

$$\text{\% Reduction} = \frac{\text{Inlet } SO_2 \text{ Rate} - \text{Outlet } SO_2 \text{ Rate}}{\text{Inlet } SO_2 \text{ Rate}} \times 100$$

Where: The Inlet SO_2 Rate is in units of lb/10^6 Btu, lb/hr, or ppmvd @ 3% O_2 and the Outlet SO_2 Rate is in the same units as the Inlet SO_2 Rate.

(8) When averaging the emissions of Unit 1 and Unit 2, compliance shall be determined in accordance with the following:

$$\text{Average ER} = \frac{[(ER_1)(HI_1) + (ER_2)(HI_2)]}{(HI_1 + HI_2)}$$

Where:

Average ER = Average Emission Rate
ER_1 = Actual Emission Rate (lb/10^6 Btu or % Reduction) of Unit 1
ER_2 = Actual Emission Rate (lb/10^6 Btu or % Reduction) of Unit 2
HI_1 = Actual Heat Input (10^6 Btu) of Unit 1
HI_2 = Actual Heat Input (10^6 Btu) of Unit 2

Notes:
- ER and HI are 30-day rolling averages.
- 30-day rolling average for the 30 successive boiler operating days as defined in Condition II.A.1.

- % Reduction can be on either a lb/10^6 Btu, ppmvd @ 3% O_2, or pounds of SO_2 basis.

5. **Recordkeeping Requirements**:

a. Great River Energy shall maintain compliance monitoring records for Unit 1 and Unit 2 as outlined in Table 1 Monitoring Records, that includes the following information:

(1) The date, place (as defined in the permit) and time of sampling or measurement.

(2) The date(s) testing was performed.

(3) The company, entity, or person that performed the testing.

(4) The testing techniques or methods used.

(5) The results of such testing.

(6) The unit load that existed at the time of sampling or measurement.

(7) The records of quality assurance for emissions measuring systems including but not limited to quality control activities, audits and calibration drifts as required by the applicable test method.

(8) A copy of all field data sheets from the emissions testing.

(9) A record shall be kept of all major maintenance activities conducted on the emission units or air pollution control equipment.

(10) Records shall be kept as to the type of fuel usage.

Table 1 Monitoring Records

Pollutant/Parameter	**Compliance Monitoring Record**
Particulate	CAM Data & Emissions Test Data
SO_2 outlet (lb/10^6 Btu)	CEM Data
SO_2 inlet (% Reduction)	CEM Data; or Coal Sampling Data & Emission Factor for Inlet SO_2 Rate
SO_2 outlet (% Reduction)	CEM Data
NO_x	CEM Data
CO_2	CEM Data

Pollutant/Parameter	**Compliance Monitoring Record**
Flow	Flow Monitor Data

b. In addition to requirements outlined in Condition II.5.a., recordkeeping for Unit 1 and Unit 2 shall be in accordance with the following applicable requirements of Chapter 33-15-06 and Chapter 33-15-14 of the North Dakota Air Pollution Control Rules and the Acid Rain Program.

(1) Section 33-15-06-05 of the North Dakota Air Pollution Control Rules, Reporting and Recordkeeping Requirements.

(2) 40 CFR 72 and 40 CFR 75.

(3) 40 CFR 64, Section 64.9 - Reporting and Recordkeeping Requirements, Paragraph (b) General Recordkeeping Requirements.

c. Great River Energy shall retain records of all required compliance monitoring data and support information for a period of at least five years from the date of the compliance monitoring sampling, measurement, report, or application. Support information includes all maintenance records of the emission units and all original strip-chart recordings/computer printouts and calibrations of the continuous compliance monitoring instrumentation, and copies of all reports required by the permit.

6. **Reporting**:

a. For Unit 1 and Unit 2, reporting shall be in accordance with the following applicable requirements of Chapter 33-15-06 and Chapter 33-15-14 of the North Dakota Air Pollution Control Rules and the Acid Rain Program.

(1) Section 33-15-06-05 of the North Dakota Air Pollution Control Rules, Reporting and Recordkeeping Requirements.

(2) 40 CFR 72 and 40 CFR 75.

(3) 40 CFR Part 64, Section 64.9 - Reporting and Recordkeeping Requirements, Paragraph (a) General Reporting Requirements.

(4) Quarterly excess emissions reports for Unit 1 and Unit 2 shall be submitted no later than the 30th day following the end of each calendar quarter. Excess emissions are defined as emissions which exceed the emission limits for Unit 1 and Unit 2 as outlined in Condition II.A.1. Data regarding only one of the two SO_2 limits needs to be included in the excess emissions report. Excess emissions shall be reported for the following:

Parameter	Reporting Period
SO_2 lb/10^6 Btu or % reduction	(30-day rolling average)
NO_x lb/10^6 Btu	(30-day rolling average)

b. Great River Energy shall submit a semi-annual report for all monitoring records required under Condition II.A.5 on forms supplied or approved by the Department. All instances of deviations from the permit must be identified in the report. A monitoring report shall be submitted within 45 days after June 30 and December 31 of each year.

c. Great River Energy shall submit an annual compliance certification report within 45 days after December 31 of each year on forms supplied or approved by the Department.

d. For emission units where the method of compliance monitoring is demonstrated by either an EPA Test Method or portable analyzer, the test report shall be submitted to the Department within 60 days after completion of the test.

e. Great River Energy shall submit an annual emission inventory report on forms supplied or approved by the Department. This report shall be submitted by March 15 of each calendar year. Insignificant units/activities listed in this permit do not need to be included in the annual emission inventory report.

f. Great River Energy shall submit to the Department written semi-annual reports detailing progress toward completion of the requirements of this permit. The semi-annual reports shall be submitted no later than 45 days after June 30 and December 31 of each year. The first report shall be due following the end of the first complete semi-annual period after the permit is issued.

g. Great River Energy shall notify the Department of the actual startup date of the equipment required to meet the BART limits.

B. **General Conditions**:

1. This permit shall in no way permit or authorize the maintenance of a public nuisance or danger to public health or safety.

2. Great River Energy shall comply with all State and Federal environmental laws and rules. In addition, Great River Energy shall comply with all local building, fire, zoning, and other applicable ordinances, codes, rules and regulations.

3. All reasonable precautions shall be taken by Great River Energy to prevent and/or minimize fugitive emissions during the construction period.

4. Great River Energy shall at all times, including periods of startup, shutdown, and malfunction, maintain and operate Unit 1 and Unit 2 and all other emission units including associated air

pollution equipment and fugitive dust suppression operations in a manner consistent with good air pollution control practices for minimizing emissions.

5. Any duly authorized officer, employee or agent of the North Dakota Department of Health may enter and inspect any property, premise or place at which the source listed in Item I.B. of this permit is or will be located at any time for the purpose of ascertaining the state of compliance with the North Dakota Air Pollution Control Rules and the conditions of this permit.

6. Any violation of a condition issued as part of this approval to construct is regarded as a violation of construction authority and is subject to enforcement action.

7. The conditions of this permit herein become, upon the effective date of this permit, enforceable by the Department pursuant to any remedies it now has or may in the future have, under the North Dakota Air Pollution Control Law, NDCC Chapter 23-25. Each and every condition of this permit is a material part thereof, and is not severable.

AIR POLLUTION CONTROL
PERMIT TO CONSTRUCT
FOR
BEST AVAILABLE RETROFIT TECHNOLOGY (BART)

Pursuant to the Air Pollution Control Rules of the State of North Dakota (North Dakota Administrative Code Article 33-15, Chapter 33-15-14 and Chapter 33-15-25), the North Dakota Department of Health hereby grants a Permit to Construct for the following BART source:

I. **General Information**:

A. **Permit to Construct Number**: TBD

B. **Source**:

1. **Name**: Stanton Generating Station

2. **Location**: Section 21, T144N, R84W, Mercer County, North Dakota

3. **Source Type**: Fossil-fuel fired steam electric plant with a nominal generating capacity of 188 megawatts.

4. **Equipment at the Facility Subject to BART**:

Unit 1 - Coal-fired boiler (nominal 1,800 x 10^6 Btu/hour heat input)

C. **Owner/Operator**:

1. **Name**: Great River Energy

2. **Address**: 12300 Elm Creek Blvd
Maple Grove, MN 55369-4718

II. **Permit Conditions**:

The Permit to Construct only establishes the BART emission limits if, and when, EPA approves those limits as part of the Regional Haze SIP. This permit allows the construction and initial operation of new or modified air pollution control equipment and process modifications at the source to comply with the BART limits. If new emission units are created, then a new Permit to Construct may be required in accordance with NDAC 33-15-14-02. The source shall be operated in accordance with the terms of this Permit to Construct and the Title V Permit to Operate until a revised Title V Permit to Operate is issued. The source is subject to all applicable rules, regulations, and orders now or hereafter in effect of the North Dakota Department of Health and to the conditions specified below:

A. **Special Conditions**:

1. **Emission Limits**: The term “30-day rolling average”, as used in this permit, shall be determined by calculating an arithmetic average of all hourly rates for the current boiler operating day and the previous 29 boiler operating days. A new 30-day rolling average shall be calculated for each boiler operating day. Each 30-day rolling average rate shall include start-up, shutdown, emergency and malfunction periods unless those periods are exempt by this permit. The 30-day rolling average emission rate is calculated as follows:

   - Calculate the hourly average emission rate for any hour in which any fuel is combusted in the boiler.

   - Calculate the daily average emission rate from the hourly average emission rates for that boiler operating day.

   - Calculate the 30-day rolling average emission rate from the daily average emission rate for the current boiler operating day and the daily average emission rate for the previous 29 boiler operating days.

   The term “boiler operating day”, as used in this permit, means any twenty-four-hour period between midnight and the following midnight during which any fuel is combusted at any time at the steam generating unit.

   a. When burning only lignite coal, Great River Energy shall not discharge or cause the discharge of sulfur dioxide (SO_2) into the atmosphere from Unit No. 1 in excess of either:

      1) 0.24 pounds per million British thermal units (lb/10^6 Btu) of heat input on a 30-day rolling average basis;

         or

      2) 10.0% of the SO_2 reaching the spray dryer inlet on a 30-day rolling average basis (90.0% reduction).

   b. When burning subbituminous coal, Great River Energy shall not discharge or cause the discharge of sulfur dioxide (SO_2) into the atmosphere from Unit No. 1 in excess of either:

      1) 0.16 pounds per million British thermal units (lb/10^6 Btu) of heat input on a 30-day rolling average basis;

         or

      2) 10.0% of the SO_2 reaching the spray dryer inlet on a 30-day rolling average basis (90.0% reduction).

c. When both lignite coal and subbituminous coal are burned in Unit 1 in a 30-day averaging period, Great River Energy shall not discharge or cause the discharge of sulfur dioxide (SO_2) into the atmosphere from Unit 1 in excess of either:

1) The SO_2 emission limit determined using the following formula:

$$E_{SO2} = (E_L H_L + E_S H_S) / (H_L + H_S)$$

Where:

E_{SO2} = SO_2 emission limit in pounds per million British thermal units ($lb/10^6$ Btu) of heat input on a 30-day rolling average basis

E_L = 0.24 $lb/10^6$ Btu of heat input

E_S = 0.16 $lb/10^6$ Btu of heat input

H_L = total heat input (in million Btu) from the combustion of lignite coal for the current operating day and the previous 29 boiler operating days

H_S = total heat input (in million Btu) from the combustion of subbituminous coal for the current operating day and the previous 29 boiler operating days

or

2) 10.0% of the SO_2 reaching the spray dryer inlet on a 30-day rolling average basis (90.0% reduction).

d. When burning only lignite coal, Great River Energy shall not discharge or cause the discharge of nitrogen oxides (NO_x) into the atmosphere from Unit No. 1 in excess of 0.29 pounds per million British thermal units ($lb/10^6$ Btu) of heat input, on a 30-day rolling average basis.

e. When burning subbituminous coal, Great River Energy shall not discharge or cause the discharge of nitrogen oxides (NO_x) into the atmosphere from Unit No. 1 in excess of 0.23 pounds per million British thermal units ($lb/10^6$ Btu) of heat input, on a 30-day rolling average basis.

f. When both lignite coal and subbituminous coal are burned in Unit 1 in a 30-day averaging period, Great River Energy shall not discharge or cause the discharge of nitrogen oxides (NO_x) into the atmosphere from Unit No. 1 in excess of the NO_x emission limit determined using the following formula:

$E_{NOX} = (E_L H_L + E_S H_S) / (H_L + H_S)$

Where:

E_{NOX} =	NO_x emission limit in pounds per million British thermal units (lb/10^6 Btu) of heat input on a 30-day rolling average basis
E_L =	0.29 lb/10^6 Btu of heat input
E_S =	0.23 lb/10^6 Btu of heat input
H_L =	total heat input (in million Btu) from the combustion of lignite coal for the current operating day and the previous 29 boiler operating days
H_S =	total heat input (in million Btu) from the combustion of subbituminous coal for the current operating day and the previous 29 boiler operating days

g. Great River Energy shall not discharge or cause the discharge of filterable (non-condensible) particulate matter (PM) into the atmosphere from Unit No. 1 in excess of 0.07 pounds per million British thermal units (lb/10^6 Btu) of heat input. Compliance with the limit is determined in accordance with the procedures in Condition II.A.4.b.(5).

h. The emission limits shall apply at all times including startup, shutdown, emergency and malfunction.

2. **Compliance Date**: Compliance with the emission limits and other requirements of this permit is required as expeditiously as practicable but in no event later than five years after the U.S. Environmental Protection Agency approves this permit as a part of the Regional Haze SIP. Compliance shall be demonstrated within 180 days of initial startup of the equipment required to meet the BART limits, but no later than five years after the U.S. EPA approves this permit as a part of the BART SIP.

3. **Continuous Emission Monitoring (CEM)**: The emissions from Unit 1 shall be measured by continuous emission monitors (CEM) for SO_2, NO_x, CO_2, and flow. The monitoring requirements under Condition II.A.4 shall be the compliance determination method for SO_2 and NO_x.

4. **Monitoring Requirements and Conditions**:

a. Requirements:

Great River Energy is only required to monitor compliance with one SO_2 limit (i.e., either the lb/10^6 Btu limit or the 90% reduction limit). If Great River Energy monitors for both limits, and compliance is indicated for one limit but not the other, no excess emissions or monitoring deviations shall be reported with respect to the other limit.

Testing and monitoring protocols used to demonstrate compliance with the emission limits of Condition II.A.1 above shall be as follows:

Pollutant/ Parameter	**Monitoring Requirement (Method)**	**Condition Number**
Particulate	Compliance Assurance Monitoring (CAM)/ Emissions Test	4.b.(6)/4.b.(5)
SO_2 (inlet)	CEM; or Coal Sampling Data & Emission Factor[a]	4.b.(1), 4.b.(2), 4.b.(3), & 4.b.(7)
SO_2 (outlet)	CEM	4.b.(1), 4.b.(2), 4.b.(3) & 4.b.(7)
NO_x	CEM	4.b.(1), 4.b.(2) & 4.b.(3)
CO_2	CEM	4.b.(1), 4.b.(2), & 4.b.(3)
Flow	Flow Monitor	4.b.(1), 4.b.(2), & 4.b.(3)

[a] Emission factor refers to the value (e.g. percentage of inlet sulfur leaving the boiler), that is determined by stack testing, which is used to calculate the scrubber SO_2 inlet rate.

b. Emission Monitoring Conditions

(1) The monitoring shall be in accordance with the following applicable requirements of Chapter 33-15-06 of the North Dakota Air Pollution Control Rules and the Acid Rain Program. Emissions are calculated using 40 CFR Part 75.

(a) Section 33-15-06-04 of the North Dakota Air Pollution Control Rules, Monitoring Requirements.

(b) 40 CFR 72 and 40 CFR 75.

(2) The Department may require additional performance audits of the CEM systems.

(3) When a failure of a continuous emission monitoring system occurs, an alternative method, acceptable to the Department, for measuring or estimating emissions must be undertaken as soon as possible. The procedures outlined in 40 CFR 75, Subpart D for substitution are considered an acceptable method for the emission rate limit. The procedures of Method 19, Paragraph 12.7, are

considered an acceptable method for the percent reduction requirement. Timely repair of the emission monitoring system must be made.

(4) Great River Energy shall maintain and operate air pollution control monitoring equipment in a manner consistent with the manufacturer's recommended Operations and Maintenance (O&M) procedures, or a site-specific O&M procedure (developed from the manufacturer's recommended O&M procedures). Great River Energy shall have the O&M procedures available on-site and provide the Department with a copy when requested.

(5) Within 180 days of initial startup of the equipment required to meet the BART limits, but not later than 5 years after approval of the Regional Haze SIP by the U.S. Environmental Protection Agency, Great River Energy shall conduct an emissions test to measure particulate emissions, using EPA Test Method 5B or Method 17 in 40 CFR Part 60, Appendix A. A test shall consist of three runs, with each run at least 120 minutes in duration and each run collecting a minimum sample of 60 dry standard cubic feet. Other EPA-approved test methods may be used provided they are approved, in advance, by the Department.

(6) Monitoring for particulate matter shall be conducted in accordance with the Compliance Assurance Monitoring (CAM) Plan developed in accordance with NDAC 33-15-14-06.10. The CAM plan revision to address the BART PM limit shall be submitted with the Title V revision application for the BART limits.

(7) In lieu of using a continuous emission monitor to determine the SO_2 reaching the spray dryer / fabric filter inlet in accordance with Condition II.A.1.a., II.A.1.b. or II.A.1.c., Great River Energy may use coal sampling and an emission factor established by stack testing. The requirements in 40 CFR 60, Appendix A, Method 19 shall be used to determine coal sampling and analysis requirements.

For purposes of determining compliance with the SO_2 percent reduction requirement, the reduction efficiency shall be determined as follows:

$$\%\text{Reduction} = \frac{\text{Inlet } SO_2 \text{ Rate} - \text{Outlet } SO_2 \text{ Rate}}{\text{Inlet } SO_2 \text{ Rate}} \times 100$$

Where: The Inlet SO_2 Rate is in units of lb/10^6 Btu, lb/hr, or ppmvd @ 3% O_2 and the Outlet SO_2 Rate is in the same units as the Inlet SO_2 Rate.

Notes:

- 30-day rolling average is determined for the 30 successive boiler operating days defined in the permit.
- % reduction can be on either a lb/10^6 Btu, ppmvd @ 3% O_2, or pounds

of SO_2 basis.

5. **Recordkeeping Requirements**:

a. Great River Energy shall maintain compliance monitoring records for Unit 1 as outlined in Table 1 Monitoring Records, that includes the following information:

(1) The date, place (as defined in the permit) and time of sampling or measurement.

(2) The date(s) testing was performed.

(3) The company, entity, or person that performed the testing.

(4) The testing techniques or methods used.

(5) The results of such testing.

(6) The unit load that existed at the time of sampling or measurement.

(7) The records of quality assurance for emissions measuring systems including but not limited to quality control activities, audits and calibration drifts as required by the applicable test method.

(8) A copy of all field data sheets from the emissions testing.

(9) A record shall be kept of all major maintenance activities conducted on the emission units or air pollution control equipment.

(10) Records shall be kept as to the type of fuel usage.

Table 1 Monitoring Records

Pollutant/Parameter	**Compliance Monitoring Record**
Particulate	CAM Data & Emissions Test Data
SO_2 outlet (lb/10^6 Btu)	CEM Data
SO_2 inlet (% Reduction)	CEM Data; or Coal Sampling Data & Emission Factor for Inlet SO_2 Rate
SO_2 outlet (% Reduction)	CEM Data
NO_x	CEM Data
CO_2	CEM Data
Flow	Flow Monitor Data

b. In addition to requirements outlined in Condition II.5.a., recordkeeping for Unit 1 shall be in accordance with the following applicable requirements of Chapter 33-15-06 and Chapter 33-15-14 of the North Dakota Air Pollution Control Rules and the Acid Rain Program:

(1) Section 33-15-06-05 of the North Dakota Air Pollution Control Rules, Reporting and Recordkeeping Requirements.

(2) 40 CFR 72 and 40 CFR 75.

(3) 40 CFR Part 64, Section 64.9 - Reporting and Recordkeeping Requirements, Paragraph (b) General Recordkeeping Requirements.

c. Great River Energy shall retain records of all required compliance monitoring data and support information for a period of at least five years from the date of the compliance monitoring sampling, measurement, report, or application. Support information includes all maintenance records of the emission units and all original strip-chart recordings/computer printouts and calibrations of the continuous compliance monitoring instrumentation, and copies of all reports required by the permit.

6. **Reporting**:

a. For Unit 1, reporting shall be in accordance with the following applicable requirements of Chapter 33-15-06 and Chapter 33-15-14 of the North Dakota Air Pollution Control Rules and the Acid Rain Program.

(1) Section 33-15-06-05 of the North Dakota Air Pollution Control Rules, Reporting and Recordkeeping Requirements.

(2) 40 CFR 72 and 40 CFR 75.

(3) 40 CFR Part 64, Section 64.9 - Reporting and Recordkeeping Requirements, Paragraph (a) General Reporting Requirements.

(4) Quarterly excess emissions reports for Unit 1 shall be submitted no later than the 30th day following the end of each calendar quarter. Excess emissions are defined as emissions which exceed the emission limits for Unit 1 as outlined in Condition II.A.1. Data regarding only one of the two SO_2 limits needs to be included in the excess emissions report. Excess emissions shall be reported for the following:

Parameter	Reporting Period
SO_2 lb/10^6 Btu or % reduction	(30-day rolling average)
NO_x lb/10^6 Btu	(30-day rolling average)

b. Great River Energy shall submit a semi-annual report for all monitoring records required under Condition II.A.5 on forms supplied or approved by the Department. All instances of deviations from the permit must be identified in the report. A monitoring report shall be submitted within 45 days after June 30 and December 31 of each year.

c. Great River Energy shall submit an annual compliance certification report within 45 days after December 31 of each year on forms supplied or approved by the Department.

d. For emission units where the method of compliance monitoring is demonstrated by either an EPA Test Method or a portable analyzer test, the test report shall be submitted to the Department within 60 days after completion of the test.

e. Great River Energy shall submit an annual emission inventory report on forms supplied or approved by the Department. This report shall be submitted by March 15 of each calendar year. Insignificant units/activities listed in this permit do not need to be included in the annual emission inventory report.

f. Great River Energy shall submit to the Department written semi-annual reports detailing progress toward completion of the requirements of this permit. The semi-annual reports shall be submitted no later than 45 days after June 30 and December 31 of each year. The first report shall be due following the end of the first complete semi-annual period after the permit is issued.

g. Great River Energy shall notify the Department of the actual startup date of the equipment required to meet the BART limits.

B. **General Conditions**:

1. This permit shall in no way permit or authorize the maintenance of a public nuisance or danger to public health or safety.

2. Great River Energy shall comply with all State and Federal environmental laws and rules. In addition, Great River Energy shall comply with all local building, fire, zoning, and other applicable ordinances, codes, rules and regulations.

3. All reasonable precautions shall be taken by Great River Energy to prevent and/or minimize fugitive emissions during the construction period.

4. Great River Energy shall at all times, including periods of startup, shutdown, and malfunction, maintain and operate Unit 1 and all other emission units including associated air pollution equipment and fugitive dust suppression operations in a manner consistent with good air pollution control practices for minimizing emissions.

5. Any duly authorized officer, employee or agent of the North Dakota Department of Health may enter and inspect any property, premise or place at which the source listed in Item I.B. of this permit is or will be located at any time for the purpose of ascertaining the state of compliance with the North Dakota Air Pollution Control Rules and the conditions of this permit.

6. Any violation of a condition issued as part of this approval to construct is regarded as a violation of construction authority and is subject to enforcement action.

7. The conditions of this permit herein become, upon the effective date of this permit, enforceable by the Department pursuant to any remedies it now has or may in the future have, under the North Dakota Air Pollution Control Law, NDCC Chapter 23-25. Each and every condition of this permit is a material part thereof, and is not severable.

AIR POLLUTION CONTROL
PERMIT TO CONSTRUCT
FOR
BEST AVAILABLE RETROFIT TECHNOLOGY (BART)

Pursuant to the Air Pollution Control Rules of the State of North Dakota (North Dakota Administrative Code Article 33-15, Chapter 33-15-14 and Chapter 33-15-25), the North Dakota Department of Health hereby grants a Permit to Construct for the following BART source:

I. **General Information**:

A. **Permit to Construct Number**: TBD

B. **Source**:

1. **Name**: Milton R. Young Station

2. **Location**: Center, North Dakota, Oliver County

3. **Source Type**: Fossil-fuel fired steam electric plant with a nameplate generating capacity of 734 megawatts.

4. **Equipment at the Facility Subject to BART**:

Unit 1 -	Lignite-fired boiler (nominal 3200 x 10^6 Btu/hour heat input)
Unit 2 -	Lignite-fired boiler (nominal 6300 x 10^6 Btu/hour heat input)

C. **Operator**:

1. **Name**: Minnkota Power Coop.

2. **Address**:
1822 Mill Road
Grand Forks, ND 58208-3200

II. **Permit Conditions**:

The Permit to Construct only establishes the BART emission limits if, and when, EPA approves those limits as part of the Regional Haze SIP. This permit allows the construction and initial operation of new or modified air pollution control equipment and process modifications at the source to comply with the BART limits. If new emission units are created, a new Permit to Construct may be required in accordance with NDAC 33-15-14-02. The source shall be operated in accordance with the terms of this Permit to Construct and the Title V Permit to Operate until a revised Title V Permit to Operate is issued. The source is subject to all applicable rules, regulations, and orders now or hereafter in effect of the North Dakota Department of Health and to the conditions specified below:

A. **Special Conditions**:

1. **Emission Limits**: The term "30-day rolling average," as used in this permit, shall be determined by calculating an arithmetic average of all hourly rates for the current boiler operating day and the previous 29 boiler operating days. A new 30-day rolling average shall be calculated for each boiler operating day. Each 30-day rolling average rate shall include start-up, shutdown, emergency and malfunction periods unless those periods are exempt by this permit. The 30-day rolling average emission rate is calculated as follows:

   - Calculate the hourly average emission rate for any hour in which any fuel is combusted in the boiler.

   - Calculate the daily average emission rate from the hourly average emission rates for that boiler operating day.

   - Calculate the 30-day rolling average emission rate from the daily average emission rate for the current boiler operating day and the daily average emission rate for the previous 29 boiler operating days.

   The term "boiler operating day," as used in this permit, means any twenty-four-hour period between midnight and the following midnight during which any fuel is combusted at any time at the steam generating unit.

   a. Minnkota shall not discharge, or cause the discharge, of sulfur dioxide (SO_2) into the atmosphere from Unit 1 in excess of 5.0% of the SO_2 reaching the inlet of the scrubber on a 30-day rolling average basis (95% reduction).

   b. Minnkota shall not discharge, or cause the discharge, of sulfur dioxide (SO_2) into the atmosphere from Unit 2 in excess of either:

      1) 0.15 lb/10^6 Btu and 10% of the SO_2 reaching the inlet of the scrubber (90.0% reduction) on a 30-day rolling average basis;

         or as an alternative

      2) 5.0% of the SO_2 reaching the inlet of the scrubber (95.0% reduction) on a 30-day rolling average basis.

      If Minnkota chooses to comply with the 95% reduction requirement at Unit 2, Minnkota may average the % reduction from Unit 1 and Unit 2 provided:

      1) The average reduction is at least 95.0% as determined in accordance with Condition II.A.4.b(8).

2) The reduction by Unit 1 is at least 95.0%, and

3) The reduction by Unit 2 is at least 90.0%.

c. Minnkota shall not discharge or cause the discharge of nitrogen oxides (NO_x) into the atmosphere from Unit 1 in excess of 0.36 pounds per million British thermal units ($lb/10^6$ Btu) of heat input and from Unit 2 in excess of 0.35 pounds per million British thermal units ($lb/10^6$ Btu), on a 30-day rolling average basis. These limits do not apply during startup. During startup, NO_x emissions from Unit 1 shall not exceed 2070.2 lb/hr on a 24-hour rolling average basis and 3995.6 lb/hr from Unit 2 on a 24-hour rolling average basis. For purposes of this permit, startup is defined as follows:

Startup is the period of time from initial fuel combustion to the point in time when the measured heat input to the boiler on a 6-hour rolling average basis is greater than or equal to 2500 x 10^6 Btu/hr for Unit 1 and 4800 x 10^6 Btu/hr for Unit 2. For purposes of determining compliance, startup cannot exceed 61 hours for Unit 1 and 115 hours for Unit 2.

d. Minnkota shall not discharge or cause the discharge of filterable particulate matter (PM) into the atmosphere in excess of the following:

Unit 1 - 0.03 $lb/10^6$ Btu
Unit 2 - 0.03 $lb/10^6$ Btu

Compliance with the limit is determined in accordance with Condition II.A.4.b.5.

e. The sulfur dioxide and particulate matter emission limits apply at all times including startup, shutdown, emergency and malfunction.

2. **Compliance Date**: Compliance with the emission limits and other requirements of this permit is required as expeditiously as practicable but in no event later than five years after the U.S. Environmental Protection Agency approves this permit as a part of the Regional Haze SIP. Compliance shall be demonstrated within 180 days of initial startup of the equipment required to meet the BART limits, but no later than five years after the U.S. Environmental Protection Agency approves this permit as a part of the BART SIP.

3. **Continuous Emission Monitoring (CEM)**: The emissions from Unit 1 (main stack) and Unit 2 (main stack) shall each be measured by continuous emission monitors (CEM) for SO_2, NO_x, CO_2, and flow. The CEM systems shall be the compliance determination method for SO_2 and NO_x.

4. **Monitoring Requirements and Conditions**:

a. Requirements:

Testing and monitoring protocols used to demonstrate compliance with the emission limits of Condition II.A.1 above shall be as follows:

Pollutant/ Parameter	**Monitoring Requirement (Method)**	**Condition Number**
Particulate	Compliance Assurance Monitoring (CAM)/ Emissions Test	4.b.(6)/4.b.(5)
SO_2 (inlet and outlet)	CEM	4.b.(1), 4.b.(2), 4.b.(3), 4.b.(7) & 4.b.(8)
NO_x	CEM	4.b.(1), 4.b.(2), 4.b.(3), & 4.b.(8)
CO_2	CEM	4.b.(1), 4.b.(2), & 4.b.(3)
Flow	Flow Monitor	4.b.(1), 4.b.(2), & 4.b.(3)

b. Emission Monitoring Conditions:

(1) The monitoring shall be in accordance with the following applicable requirements of Chapter 33-15-06 ~~1~~ of the North Dakota Air Pollution Control Rules and the Acid Rain Program. Emissions are calculated using 40 CFR Part 75.

(a) Section 33-15-06-04 of the North Dakota Air Pollution Control Rules, Monitoring Requirements.

(b) 40 CFR 72 and 40 CFR 75.

(2) The Department may require additional performance audits of the CEM systems.

(3) When a failure of a continuous emission monitoring system occurs, an alternative method, acceptable to the Department, for measuring or estimating emissions must be undertaken as soon as possible. The procedures outlined in 40 CFR 75, Subpart D for substitution are considered an acceptable method for the emission rate limit. The procedures of Method 19, Paragraph 12.7, are considered an acceptable method for the percent reduction requirement. Timely repair of the emission monitoring system must be made.

(4) Minnkota shall maintain and operate air pollution control monitoring equipment in a manner consistent the manufacturer's recommended Operations and Maintenance (O&M) procedures, or a site-specific O&M

procedure (developed from the manufacturer's recommended O&M procedures). Minnkota shall have the O&M procedures available on-site and provide the Department with a copy when requested.

(5) Within 180 days of initial startup of the equipment required to meet the BART limits, but not later than 5 years after approval of the Regional Haze SIP by the U.S. Environmental Protection Agency, Minnkota shall conduct an emissions test to measure particulate emissions, using EPA Test Method 5B or Method 17 in 40 CFR Part 60, Appendix A. A test shall consist of three runs, with each run at least 120 minutes in duration and each run collecting a minimum sample of 60 dry standard cubic feet. Other EPA approved test methods may be used provided they are approved, in advance, by the Department.

(6) Monitoring for particulate matter shall be conducted in accordance with the Compliance Assurance Monitoring (CAM) Plan developed in accordance with NDAC 33-15-14-06.10. The CAM plan revision to address the BART PM limit shall be submitted with the Title V permit revision application for the BART limits.

(7) For purposes of determining compliance with the SO_2 percent reduction requirement, the reduction efficiency shall be determined as follows:

$$\% \text{ Reduction} = \frac{\text{Inlet } SO_2 \text{ Rate} - \text{Outlet } SO_2 \text{ Rate}}{\text{Inlet } SO_2 \text{ Rate}} \times 100$$

Where: The Inlet SO_2 Rate and Outlet SO_2 Rate are in units of lb/10^6 Btu (30-day rolling average).

(8) When averaging the SO_2 emissions of Unit 1 and Unit 2, compliance shall be determined in accordance with the following:

$$\text{Average } \% \text{ Reduction} = \frac{[(ER_1)(HI_1) + (ER_2)(HI_2)]}{(HI_1 + HI_2)}$$

ER_1 = Actual % Reduction of Unit 1
ER_2 = Actual % Reduction of Unit 2
HI_1 = Actual Heat Input (MMBtu) of Unit 1
HI_2 = Actual Heat Input (MMBtu) of Unit 2

Notes:

- ER and HI are 30-day rolling averages.
- 30-day rolling average for the 30 successive boiler operating days as defined in Condition II.A.1.
- % Reduction is on a lb/10^6 Btu of SO_2 basis.

5. **Recordkeeping Requirements**:

a. Minnkota shall maintain compliance monitoring records for Unit 1 and Unit 2 as outlined in Table 1 Monitoring Records, that includes the following information:

(1) The date, place (as defined in the permit) and time of sampling or measurement.

(2) The date(s) testing was performed.

(3) The company, entity, or person that performed the testing.

(4) The testing techniques or methods used.

(5) The results of such testing.

(6) The unit load that existed at the time of sampling or measurement.

(7) The records of quality assurance for emissions measuring systems including but not limited to quality control activities, audits and calibration drifts as required by the applicable test method.

(8) A copy of all field data sheets from the emissions testing.

(9) A record shall be kept of all major maintenance activities conducted on the emission units or air pollution control equipment.

(10) Records shall be kept as to the type of fuel usage.

Table 1 Monitoring Records

Pollutant/Parameter	Compliance Monitoring Record
Particulate	CAM Data & Emissions Test Data
SO_2 (lb/10^6 Btu) inlet and outlet	CEM Data
SO_2 (% Reduction) inlet and outlet	CEM Data
NO_x	CEM Data
CO_2	CEM Data
Flow	Flow Monitor Data

b. In addition to requirements outlined in Condition II.5.a., recordkeeping for Unit 1 and Unit 2 shall be in accordance with the following applicable requirements of

Chapter 33-15-06 and Chapter 33-15-14 of the North Dakota Air Pollution Control Rules and the Acid Rain Program:

(1) Section 33-15-06-05 of the North Dakota Air Pollution Control Rules, Reporting and Recordkeeping Requirements.

(2) 40 CFR 72 and 40 CFR 75.

(3) 40 CFR Part 64, Section 64.9 - Reporting and Recordkeeping Requirements, Paragraph (b) General Recordkeeping Requirements.

c. Minnkota shall retain records of all required compliance monitoring data and support information for a period of at least five years from the date of the compliance monitoring sampling, measurement, report, or application. Support information includes all maintenance records of the emission units and all original strip-chart recordings/computer printouts and calibrations of the continuous compliance monitoring instrumentation, and copies of all reports required by the permit.

6. **Reporting**:

a. For Unit 1 and Unit 2, reporting shall be in accordance with the following applicable requirements of Chapter 33-15-06 and Chapter 33-15-14 of the North Dakota Air Pollution Control Rules and the Acid Rain Program.

(1) Section 33-15-06-05 of the North Dakota Air Pollution Control Rules, Reporting and Recordkeeping Requirements.

(2) 40 CFR 72 and 40 CFR 75.

(3) 40 CFR Part 64, Section 64.9 - Reporting and Recordkeeping Requirements, Paragraph (a) General Reporting Requirements.

(4) Quarterly excess emissions reports for Unit 1 and Unit 2 shall be submitted no later than the 30th day following the end of each calendar quarter. Excess emissions are defined as emissions which exceed the emission limits for Unit 1 and Unit 2 as outlined in Condition II.A.1. For Unit 2, data regarding only one of the two alternative SO_2 limits must be included in the excess emissions report. Excess emissions shall be reported for the following:

Parameter	Reporting Period
SO_2 lb/10^6 Btu	(30-day rolling average)
	SO_2 percent emitted (reduction) (30-day rolling average)
NO_x lb/10^6 Btu	(30-day rolling average)

NO_x lb/hr (startup)	(24-hour rolling average)

b. Minnkota shall submit a semi-annual report for all monitoring records required under Condition II.A.5 on forms supplied or approved by the Department. All instances of deviations from the permit must be identified in the report. A monitoring report shall be submitted within 45 days after June 30 and December 31 of each year.

c. Minnkota shall submit an annual compliance certification report within 45 days after December 31 of each year on forms supplied or approved by the Department.

d. For emission units where the method of compliance monitoring is demonstrated by either an EPA Test Method or a portable analyzer test, the test report shall be submitted to the Department within 60 days after completion of the test.

e. Minnkota shall submit an annual emission inventory report on forms supplied or approved by the Department. This report shall be submitted by March 15 of each calendar year. Insignificant units/activities listed in this permit do not need to be included in the annual emission inventory report.

f. Minnkota shall submit to the Department written semi-annual reports detailing progress toward completion of the requirements of this permit. The semi-annual reports shall be submitted no later than 45 days after June 30 and December 31 of each year. The first report shall be due following the end of the first complete semi-annual period after the permit is issued.

g. Minnkota shall notify the Department of the actual startup date of the equipment required to meet the BART limits.

B. **General Conditions**:

1. This permit shall in no way permit or authorize the maintenance of a public nuisance or danger to public health or safety.

2. Minnkota shall comply with all State and Federal environmental laws and rules. In addition, Minnkota shall comply with all local building, fire, zoning, and other applicable ordinances, codes, rules and regulations.

3. All reasonable precautions shall be taken by Minnkota to prevent and/or minimize fugitive emissions during the construction period.

4. Minnkota shall at all times, including periods of startup, shutdown, and malfunction, maintain and operate Unit 1 and Unit 2 and all other emission units including associated air pollution equipment and fugitive dust suppression operations in a manner consistent with good air pollution control practices for minimizing emissions.

5. Any duly authorized officer, employee or agent of the North Dakota Department of Health may enter and inspect any property, premise or place at which the source listed in Item I.B. of this permit is or will be located at any time for the purpose of ascertaining the state of compliance with the North Dakota Air Pollution Control Rules and the conditions of this permit.

6. Any violation of a condition issued as part of this approval to construct is regarded as a violation of construction authority and is subject to enforcement action.

7. The conditions of this permit herein become, upon the effective date of this permit, enforceable by the Department pursuant to any remedies it now has or may in the future have, under the North Dakota Air Pollution Control Law, NDCC Chapter 23-25. Each and every condition of this permit is a material part thereof, and is not severable.

1 Introduction

The EPA Regional Haze Rule[1] (Rule) specifies that modeling must be conducted to demonstrate reasonable progress toward the goal of achieving natural visibility in each PSD Class I area. The Rule also specifies that natural visibility conditions should be achieved by 2064. The uniform rate of progress defines the visibility improvement that would be needed each year, starting with the base period of 2000-2004, to achieve natural visibility conditions in 2064 in each Class I area. This progression is illustrated in Figure 1-1. To track visibility improvement, the Rule specifies several milestone dates for meeting intermediate reasonable progress goals, that the State must establish, the first of which is the 2018 goal, for each Class I area. The uniform rate of progress for 2018 is determined by interpolating from the uniform rate of progress path, as illustrated in Figure 1-1. This protocol will assume that the 2018 goal for each Class I area is the glide path (uniform rate of progress), but the reasonable progress goal established by the State for 2018 for each Class I area may or may not be equal to the uniform rate of progress for 2018.

To demonstrate reasonable progress with respect to the 2018 visibility goals, the Rule specifies that visibility on the 20% worst days must improve enough to meet the goal, while visibility on the 20% best days must not deteriorate, between the base period (2000-2004) and 2018. Air quality modeling will be used to project future visibility, accounting for proposed BART controls and other visibility-affecting emissions increases/decreases. Modeling will be used in a relative sense. Baseline and projected future emission inventories will be modeled to develop a future/baseline prediction ratio (relative response factor). The ratio will then be applied to baseline monitoring data for visibility-affecting species to project future visibility.

The Western Regional Air Partnership (WRAP) regional planning organization has established a Regional Modeling Center (RMC) to assist member States, including North Dakota, with modeling to determine status with respect to the 2018 goals. The RMC is applying a chemically sophisticated grid model (CMAQ), on a regional basis, to project future visibility in Class I areas in the WRAP region[2]. The RMC has developed comprehensive base period and future period visibility-affecting emission inventories to use with CMAQ, and has performed numerous studies using base period model and monitoring data to evaluate CMAQ performance[3].

Though the North Dakota Department of Health (NDDoH) intends to incorporate much of the WRAP RMC work in its own analysis of visibility goals in North Dakota Class I areas, the NDDoH recognized it would have to develop its own modeling capability for visibility projection

---

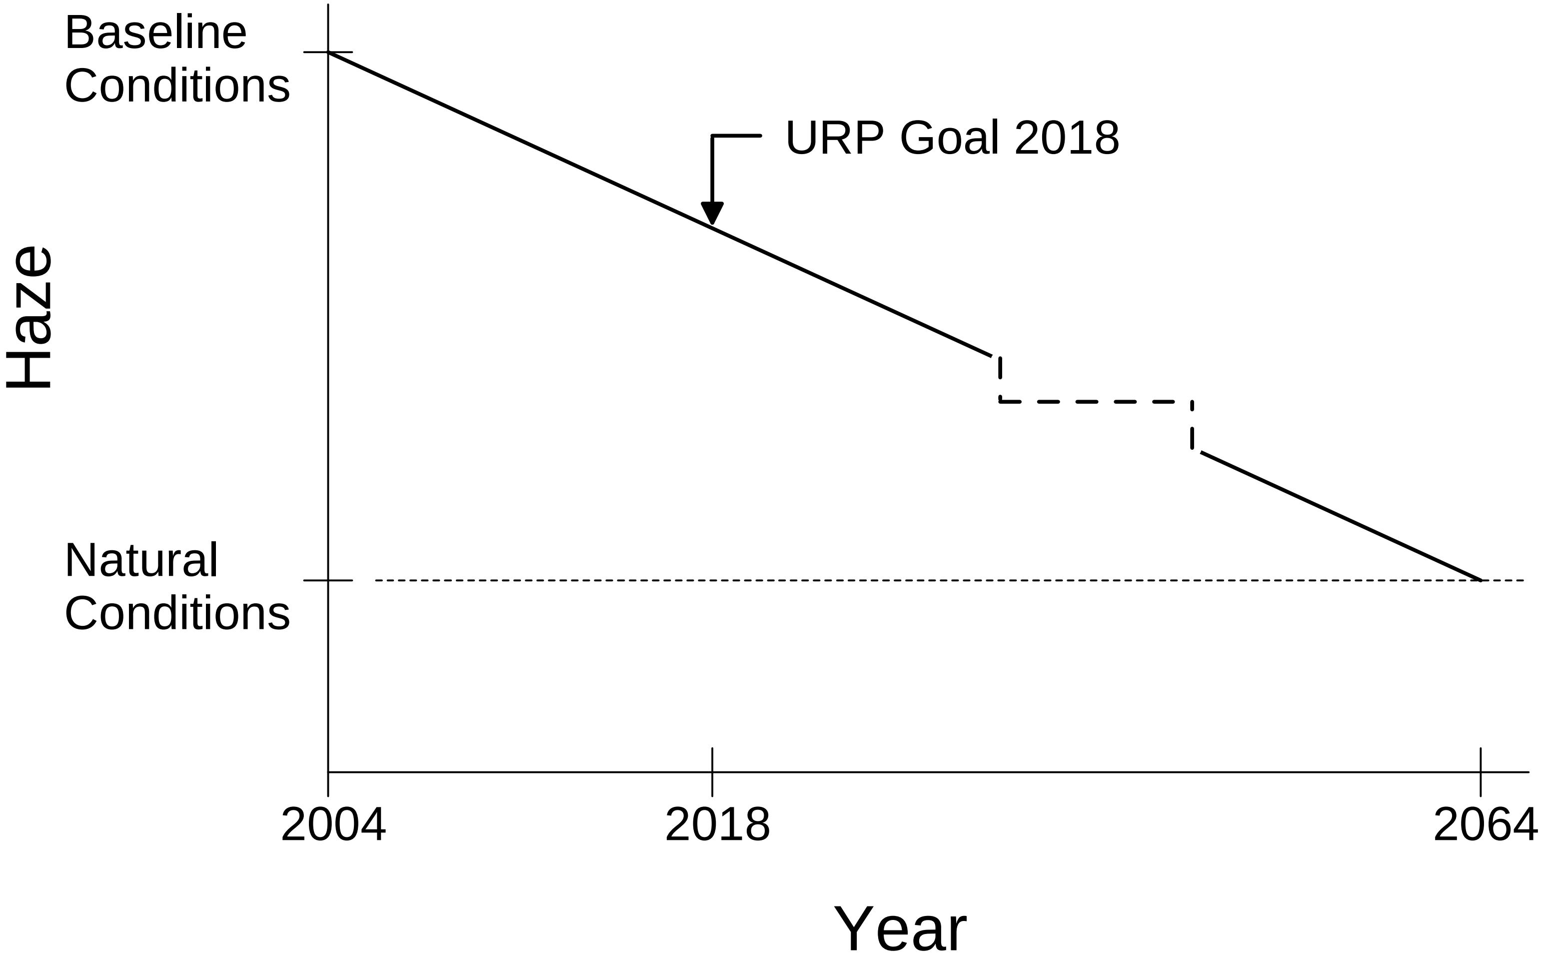
[3] See WRAP RMC web site at http://pah.cert.ucr.edu/aqm/308/

Figure 1-1
Regional Haze Uniform Rate of Progress



in order to address weight of evidence issues not included in WRAP modeling, such as discounting the impact of international sources. Further, the NDDoH had concerns regarding the resolution of the WRAP CMAQ simulations, particularly for large point sources.

The RMC is applying CMAQ on a National basis using a grid resolution of 36 km, with no plume-in-grid treatment. This means that emissions from point sources are immediately mixed uniformly throughout a 36 km (square) grid cell volume, which may overstate the dilution of the plume, and the speed of chemical reactions for species contained in the plume, especially for sources located relatively near Class I areas. Consequently, the contribution of visibility-affecting species from these sources may be misrepresented for both base period and future period modeling. This limitation in treatment of point sources is recognized in CMAQ documentation[4].

To provide a local modeling capability, the NDDoH proposes a hybrid modeling approach for determining status with respect to the visibility goals. This approach involves nesting the local NDDoH CALPUFF domain within the WRAP National CMAQ domain, and applying the Lagrangian CALPUFF model in a retrospective sense to more realistically define plume geometry for local point sources. To implement the nesting, hourly output concentrations from WRAP CMAQ will be used to set hourly boundary conditions for CALPUFF. The use of CMAQ output to set CALPUFF boundary conditions has been suggested by Escoffier-Czaja and Scire[5]. Location of the NDDoH CALPUFF domain within the National CMAQ domain is illustrated in Figure 1-2.

CALPUFF nesting will be used for simulation of SO_2-SO_4-NO_X-HNO_3-NO_3 chemistry and transport, and thus sulfate and nitrate predictions, only. Results for all other visibility-affecting species, including organic carbon mass, elemental carbon, fine particulate, and coarse particulate, will be obtained directly from the CMAQ output for the grid cell containing the subject Class I area IMPROVE monitor. CMAQ output will be combined with CALPUFF results for sulfate and nitrate in order to perform necessary light extinction calculations. In this way, the NDDoH will take advantage of the sophistication of the RMC approach for other particulate components, which reflect a very small percentage of emissions from the local point sources of concern.

The NDDoH protocol for modeling visibility progress goals will generally adhere to EPA *Guidance on the Use of Models and Other Analyses for Demonstrating Attainment of Air Quality*

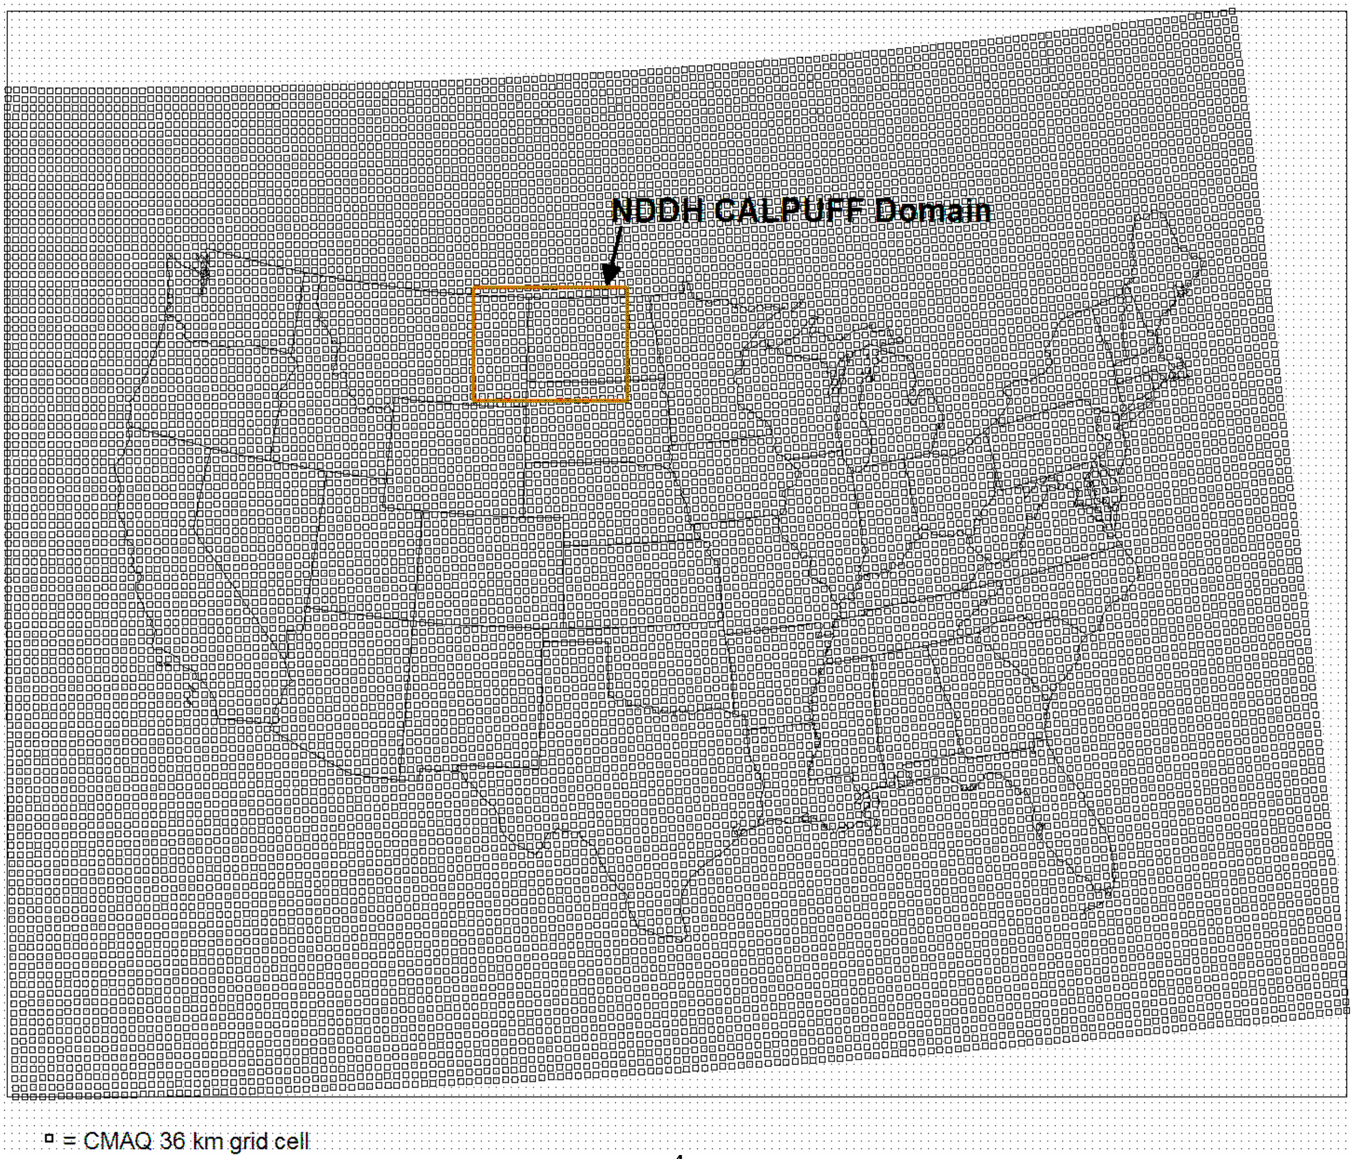
Figure 1-2
WRAP CMAQ Domain and NDDoH CALPUFF Domain



Goals for Ozone, $PM_{2.5}$, and Regional Haze[6]. An evaluation of performance for the CMAQ-CALPUFF hybrid modeling system will be conducted first. Then baseline (2000-2004) and future (2018) emission scenarios will be modeled, using the hybrid modeling system, in order to develop relative response factors (RRF's). Finally, RRF's will be applied to baseline IMPROVE monitoring data to project future visibility in North Dakota Class I areas. These Class I areas include Theodore Roosevelt National Park (TRNP) and Lostwood National Wilderness Area (NWA). Locations of North Dakota Class I areas, IMPROVE monitor sites, and major visibility-affecting sources are depicted in Figure 1-3.

2 Regional Haze Metrics

Metrics used to assess regional haze include light extinction and deciview. Calculation of light extinction from visibility affecting aerosols for the NDDoH regional haze analysis will be based on the "new" IMPROVE algorithm[7]. This new equation was seen to reduce bias associated with use of the "old" IMPROVE algorithm, and was adopted as an alternative by the IMPROVE Steering Committee in December 2005. The new algorithm splits ammonium sulfate, ammonium nitrate, and organic mass concentrations into two fractions: small and large. The new algorithm for light extinction is:

$$\begin{aligned} b_{ext} = \; & 2.2 \text{ x } f_s(RH) \text{ x [small sulfate]} + 4.8 \text{ x } f_L(RH) \text{ x [large sulfate]} \\ & + 2.4 \text{ x } f_s(RH) \text{ x [small nitrate]} + 5.1 \text{ x } f_L(RH) \text{ x [large nitrate]} \\ & + 2.8 \text{ x [small organic mass]} + 6.1 \text{ x [large organic mass]} \\ & + 10.0 \text{ x [elemental carbon]} \\ & + 1.0 \text{ x [fine soil]} \\ & + 1.7 \text{ x } f_{ss}(RH) \text{ x [sea salt]} \\ & + 0.6 \text{ x [coarse mass]} \\ & + \text{Rayleigh scattering (site-specific)} \\ & + 0.33 \text{ x } [NO_2 \text{ (ppb)}] \end{aligned}$$

where

b_{ext} = light extinction in units of inverse megameters (Mm^{-1}),
$f_s(RH)$ = function of relative humidity for small size fraction,

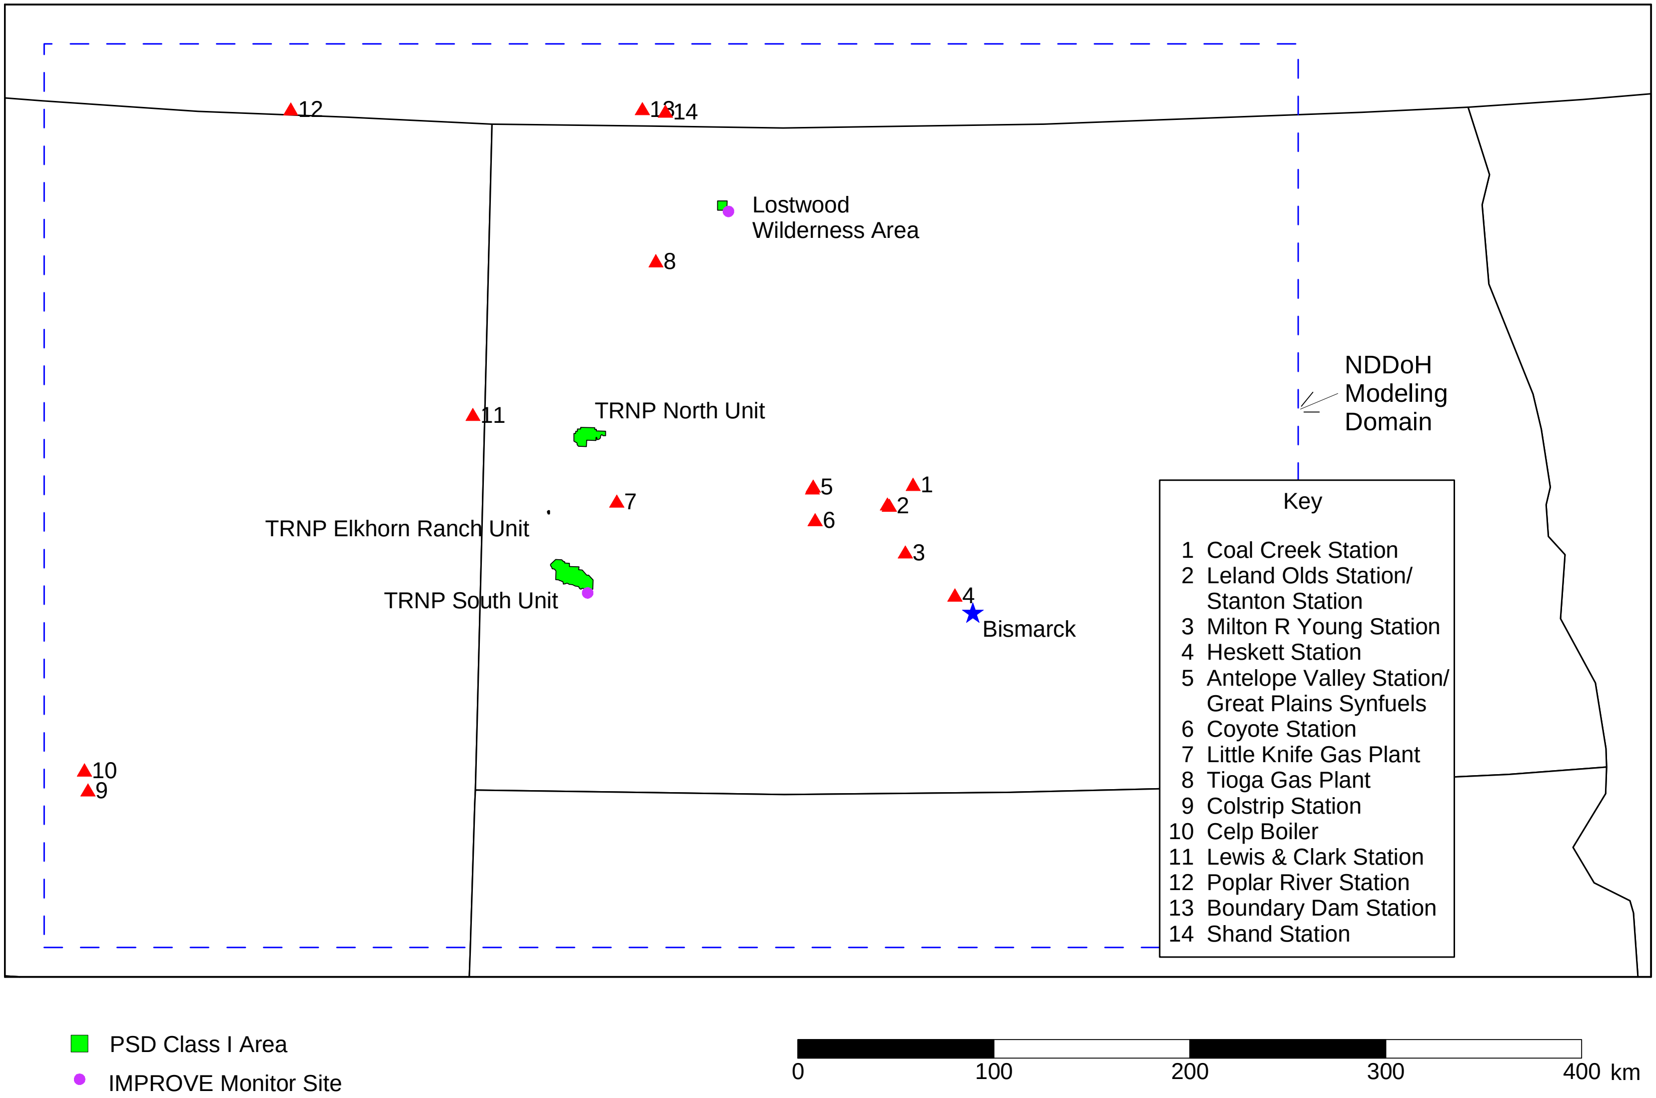
[7] IMPROVE, 2005. New IMPROVE algorithm for estimating light extinction approved for use. The IMPROVE Newsletter, Volume 14, Number 4. Air Resource Specialists, Inc., Fort Collins, CO 80525.

Figure 1-3
Major Sources and PSD Class I Areas



$f_L(RH)$ = function of relative humidity for large size fraction,
$f_{ss}(RH)$ = function of relative humidity for sea salt,
all species concentrations are provided in ug/m^3,
sulfate/nitrate implies ammonium sulfate / ammonium nitrate.

Apportionment of total sulfate concentrations into small and large size fractions is defined:

$$[\text{large sulfate}] = \frac{\underline{[\text{total sulfate}]}}{20\ ug/m^3} \times [\text{total sulfate}], \quad \text{for } [\text{total sulfate}] < 20\ ug/m^3$$

$$[\text{large sulfate}] = [\text{total sulfate}], \quad \text{for } [\text{total sulfate}] \geq 20\ ug/m^3$$

$$[\text{small sulfate}] = [\text{total sulfate}] - [\text{large sulfate}]$$

The same equations are used to apportion nitrate and organic mass size fractions.

WRAP and the NDDoH have determined that the NO_2 term has very little impact on total extinction, and the IMPROVE network does not include NO_2 monitoring. A review of observational NO_2 data from an NDDoH monitoring site in Theodore Roosevelt National Park revealed that readings were less than the minimum detectable level of 2.0 ppb more than 80% of the time in 2002. WRAP has not accounted for the NO_2 term in it's analyses for future visibility. Accordingly, the NDDoH proposes to omit the NO_2 term when implementing the new extinction algorithm.

Regarding the sea salt term in the extinction equation, very little impact from sea salt is expected in North Dakota. However, IMPROVE monitoring data in North Dakota Class I areas does occasionally include small values for sea salt. Because of the negligible impact of sea salt in the IMPROVE equation for North Dakota Class I areas, the impact would remain negligible even if some variation in sea salt occurs in the future. Therefore, sea salt will be omitted from the modeling process and an RRF of 1.0 will be assumed.

Light extinction is converted to deciview using the following relationship:

$$dv = 10 \times \ln(b_{ext} / 10)$$

where

dv = deciview
b_{ext} = light extinction in units of inverse megameters (Mm^{-1})

Visibility goals are generally expressed as deciviews. A change of one deciview represents a generally perceptible change in visibility to most people.

3 Overview of Methodology

3.1 General

Methodology for NDDoH projection of future visibility is based on EPA *Guidance on the Use of Models and Other Analyses for Demonstrating Attainment of Air Quality Goals for Ozone, $PM_{2.5}$, and Regional Haze* [8]. The guidance proposes a relative modeling approach to project future (2018) visibility, in order to determine compliance status with respect to visibility goals at Class I areas. Implementation of the relative modeling approach relies on relative response factors (RRF's) which represent the modeled impact of the future (visibility affecting) source inventory divided by the modeled impact of the baseline source inventory at Class I areas. These RRF's are applied to baseline IMPROVE monitoring data to project future visibility.

Projection of future visibility is needed for the 20% worst and 20% best visibility days at each Class I area. The 20% worst days and 20% best days are determined from Class I area IMPROVE monitoring data for each year for the 5-year baseline period 2000-2004. Because IMPROVE sampling occurs once every three days, the maximum number of monitored days per year would be 122, and the maximum number of 20% worst (best) days per year would be 24.

According to the EPA guidance, RRF's are developed by comparing the future average predicted concentration for 20% worst days (best days) to the baseline average predicted concentration for 20% worst days (best days), for each species. The 20% worst (best) modeled days are selected for consistency with the worst (best) monitored days (i.e., represent the same temporal periods), assuming modeling is based on 2000-2004 meteorological data. For each visibility affecting species (SO_4, NO_3, OMC, EC, Soil, CM), a single RRF is developed for each Class I area. The RRF is calculated by dividing the predicted future concentration averaged over all worst (best) days by the predicted baseline concentration averaged over all worst (best) days. Then, future concentrations for each species are projected by multiplying the RRF by the observed species concentration on each of the baseline worst (best) days.

The RRF approach can be expressed mathematically:

$$X^{i,j}_{of} = X^{i,j}_{ob}\,(RRF^{i}) = X^{i,j}_{ob}\,(\overline{X}^{i}_{pf}/\overline{X}^{i}_{pb})$$

where

$X^{i,j}_{of}$ represents projected **o**bserved **f**uture concentration for species i on day j (each of 20% worst days for each baseline year),

$X^{i,j}_{ob}$ represents **o**bserved **b**aseline (IMPROVE data) concentration for species i on day j (each of 20% worst days for each baseline year),

---

[8] See Supra note 6

$\overline{X}^i_{pf}$ represents average **p**redicted **f**uture concentration for species i (average of 20% worst days),

$\overline{X}^i_{pb}$ represents average **p**redicted **b**aseline concentration for species i (average of 20% worst days),

RRF^i represents the relative response factor for species i.

The projected future worst-day (best-day) concentrations are converted to light extinction using the IMPROVE equation, then daily light extinction is converted to deciview for each day. Finally, projected daily deciview is averaged over all worst-case (best-case) days for each year, then averaged over all years to produce the single future value needed to address visibility goals for each Class I area.

The NDDoH will implement the approach described above. The WRAP RMC has previously developed emission inventories (baseline and future), conducted modeling, and projected future visibility for the WRAP region Class I IMPROVE sites using the CMAQ grid model[9]. But to address weight of evidences issues, and possibly concerns about the resolution of the WRAP CMAQ simulations, the NDDoH needed an in-house modeling capability. The RMC is applying CMAQ on a National basis using a grid resolution of 36 km, with no plume-in-grid treatment. As such, dilution of point source plumes, and the speed of chemical reactions for species contained in the plume, may be overstated, particularly for large sources located relatively near Class I areas.

The NDDoH proposes to apply a hybrid modeling procedure by nesting the local NDDoH CALPUFF domain within the WRAP National CMAQ domain, and applying the Lagrangian CALPUFF model in a retrospective sense to more realistically define plume geometry for local point sources. To implement the nesting, hourly output concentrations from WRAP CMAQ will be used to set hourly boundary conditions for CALPUFF. The NDDoH will prepare baseline and future emission inventories for the CALPUFF domain, and will include the effect of proposed BART controls in the future inventory. CMAQ output used to set CALPUFF boundary conditions will reflect corresponding WRAP cases for baseline and future emission inventories. After this modeling system has been applied, the baseline and future case output from CALPUFF will be used to develop RRF’s.

The hybrid modeling approach will be used for simulation of SO_2-SO_4-NO_X-HNO_3-NO_3 chemistry and transport, and thus sulfate and nitrate predictions, only. The larger sources located relatively near North Dakota Class I areas, where CMAQ dilution is a concern, are primarily emitters of SO_2 and NO_X. Further, IMPROVE measurements at North Dakota Class I areas indicate that sulfate and nitrate are primary contributors to light extinction on most worst-case days. Individual species contribution to light extinction for worst-case days at Theodore

---

[9] See Supra note 2

Roosevelt National Park is illustrated in Figure 3-1. Therefore, weight of evidence assessments will be most applicable to sulfate and nitrate species.

For all other visibility-affecting species, including OMC, EC, Soil, and CM, predictions needed for developing RRF's will be taken directly from CMAQ output. WRAP CMAQ output from the grid cell containing the subject Class I area IMPROVE site for baseline and future cases will be utilized. In this way, the NDDoH will take advantage of the extensive work WRAP has undertaken to develop accurate model emissions inventories for OMC-EC-Soil-CM species and precursors. CMAQ output for these species will be combined with hybrid modeling results for sulfate and nitrate in order to project future concentrations necessary for light extinction calculations for worst (best) days.

Along with setting boundary conditions, WRAP CMAQ data will be used for developing area source emissions inventories within the CALPUFF domain. The NDDoH will develop it's own point source inventory for SO_2 and NO_X, but will rely on WRAP CMAQ data for all other source categories (and for point source SO_4 and NO_3) to apportion emissions within the CALPUFF domain. WRAP is using the SMOKE emissions model[10] to develop the emissions inventory for CMAQ. The NDDoH will request and further process SMOKE output to define area source emissions for the CALPUFF domain. The CALPUFF area source emissions inventory will include the species SO_2, SO_4, NO_X, and NO_3. In addition, primary SO_4 and NO_3 emissions data will be extracted from the SMOKE inventory for point sources, and apportioned to the CALPUFF domain as area sources. WRAP CMAQ source categories to be included in the CALPUFF emissions inventory are outlined in Table 3-1. Note that WRAP SMOKE output did not contain all four species for some source categories.

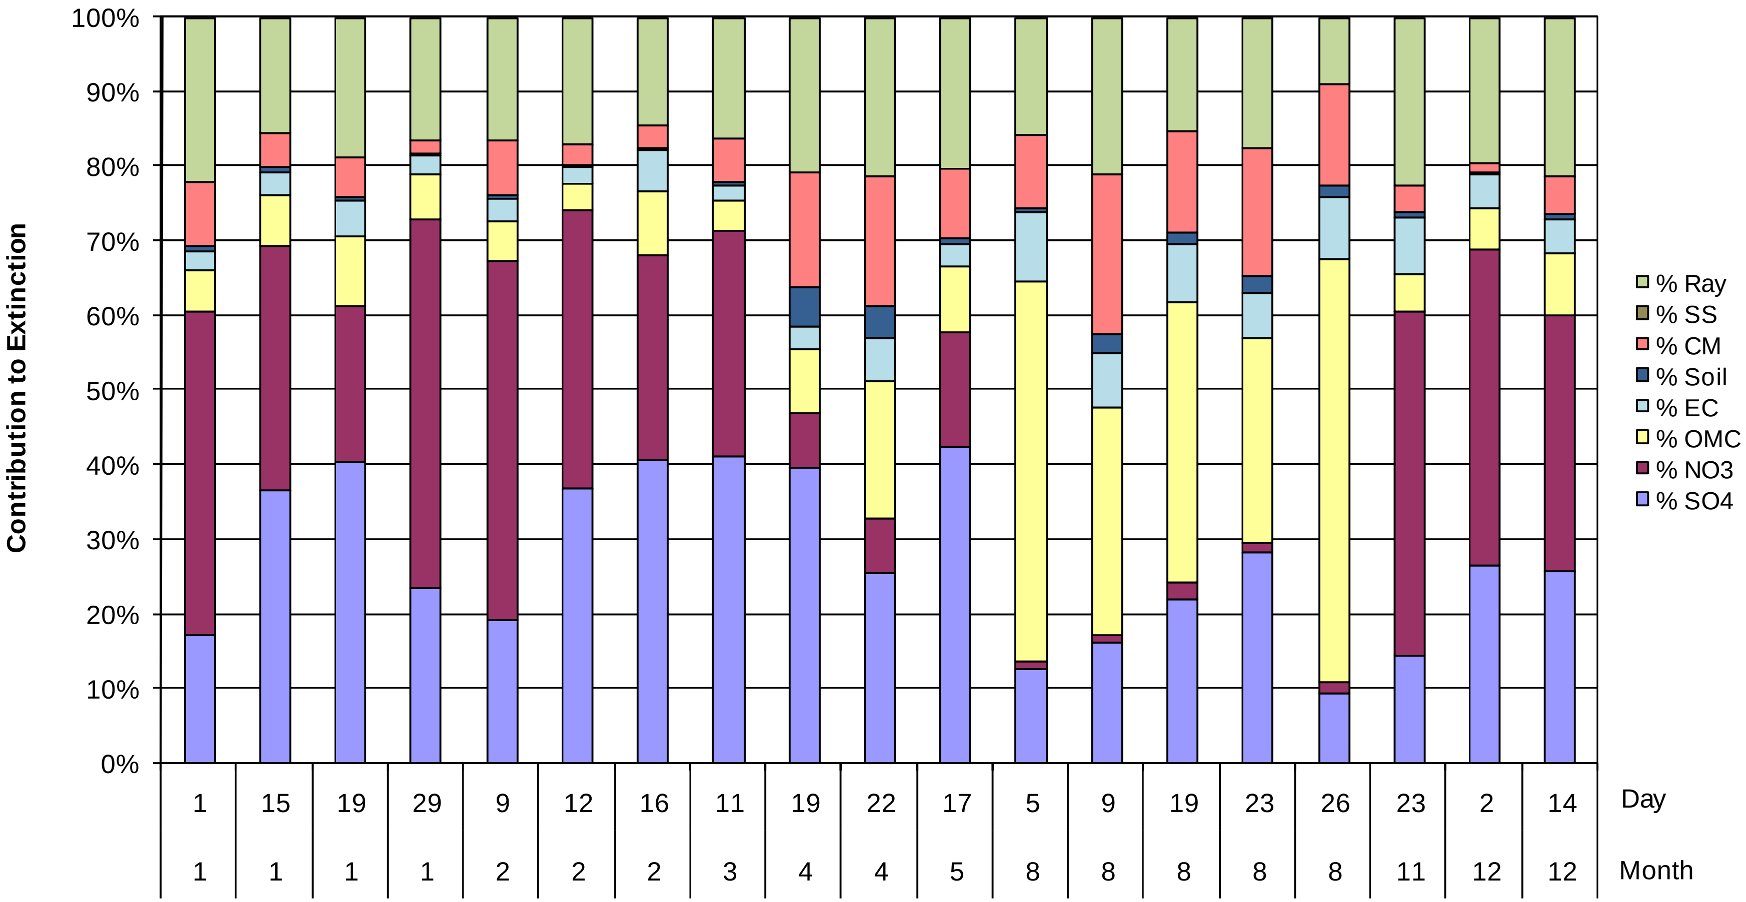
Table 3-1
CMAQ-CALPUFF Area Source Categories

Source Category	Species Included
All Fires	SO_2, NO_X, SO_4, NO_3
Biogenics	NO_X
Fugitive Dust	SO_4, NO_3
On-Road Mobile	SO_2, NO_X, SO_4
Off-Road Mobile	SO_2, NO_X, SO_4, NO_3
Road Dust	SO_4, NO_3
Oil & Gas	SO_2, NO_X
Conventional Area	SO_2, NO_X, SO_4, NO_3
Point	SO_4, NO_3

---

[10] University of North Carolina, 2007. SMOKE User's Manual. The Institute for the Environment, University of North Carolina.

Figure 3-1
IMPROVE 20% Worst Days – TRNP 2000



The proposed interfacing of CMAQ and CALPUFF modeling systems for the hybrid approach is illustrated in the flow diagram in Figure 3-2. Necessary software for processing SMOKE emissions and CMAQ concentration data will be developed by the NDDoH. The software will be made available for public review.

Prior to baseline and future case CALPUFF modeling, the NDDoH will undertake a model performance evaluation. This evaluation will focus on the performance of the hybrid CMAQ-CALPUFF modeling system for sulfate and nitrate. As indicated previously, the CMAQ performance evaluations conducted by WRAP for OMC, EC, Soil, and CM species also apply.

The NDDoH will obtain CMAQ emissions input data (SMOKE output) and hourly concentration output files from the WRAP RMC. CMAQ data used to set CALPUFF boundary conditions and develop the CALPUFF area source inventory will be based on WRAP cases BASE02b, PLAN02d, and PRP18a, for performance evaluation, baseline case, and future case modeling, respectively. These WRAP scenarios are described as follows.

- Case BASE02b reflects CMAQ modeling using year 2002 emissions with year 2002 meteorology. WRAP is using this case for performance evaluations.

- Case PLAN02d reflects CMAQ modeling using composite 2000-2004 emissions with 2002 meteorology. WRAP is using this case for the base period to generate relative response factors.

- Case PRP18a (Preliminary Reasonable Progress 18a) reflects CMAQ modeling using projected year 2018 emissions with 2002 meteorology. Case PRP18a represents base period emissions projected to 2018, accounting for preliminary estimates of the effect of BART controls, and assuming other growth and control factors. WRAP is using this case for the future period, on an interim basis, to generate relative response factors.

WRAP will eventually be refining it's PRP18a case in order to more accurately represent the effect of BART and other controls. The NDDoH will request data from the updated CMAQ case(s) when available, and revise the future case modeling.

WRAP RMC has conducted CMAQ modeling for the above cases using 2002 meteorological data, only. Therefore, the hybrid modeling conducted by the NDDoH will be limited to this single year of meteorological data. The RRF's developed from 2002 modeling will be applied to all five years of baseline monitoring data (2000-2004) to project future visibility. To the extent applicable, CALMET-CALPUFF input settings for regional haze modeling will be consistent with those specified in the North Dakota BART modeling protocol[11].

---

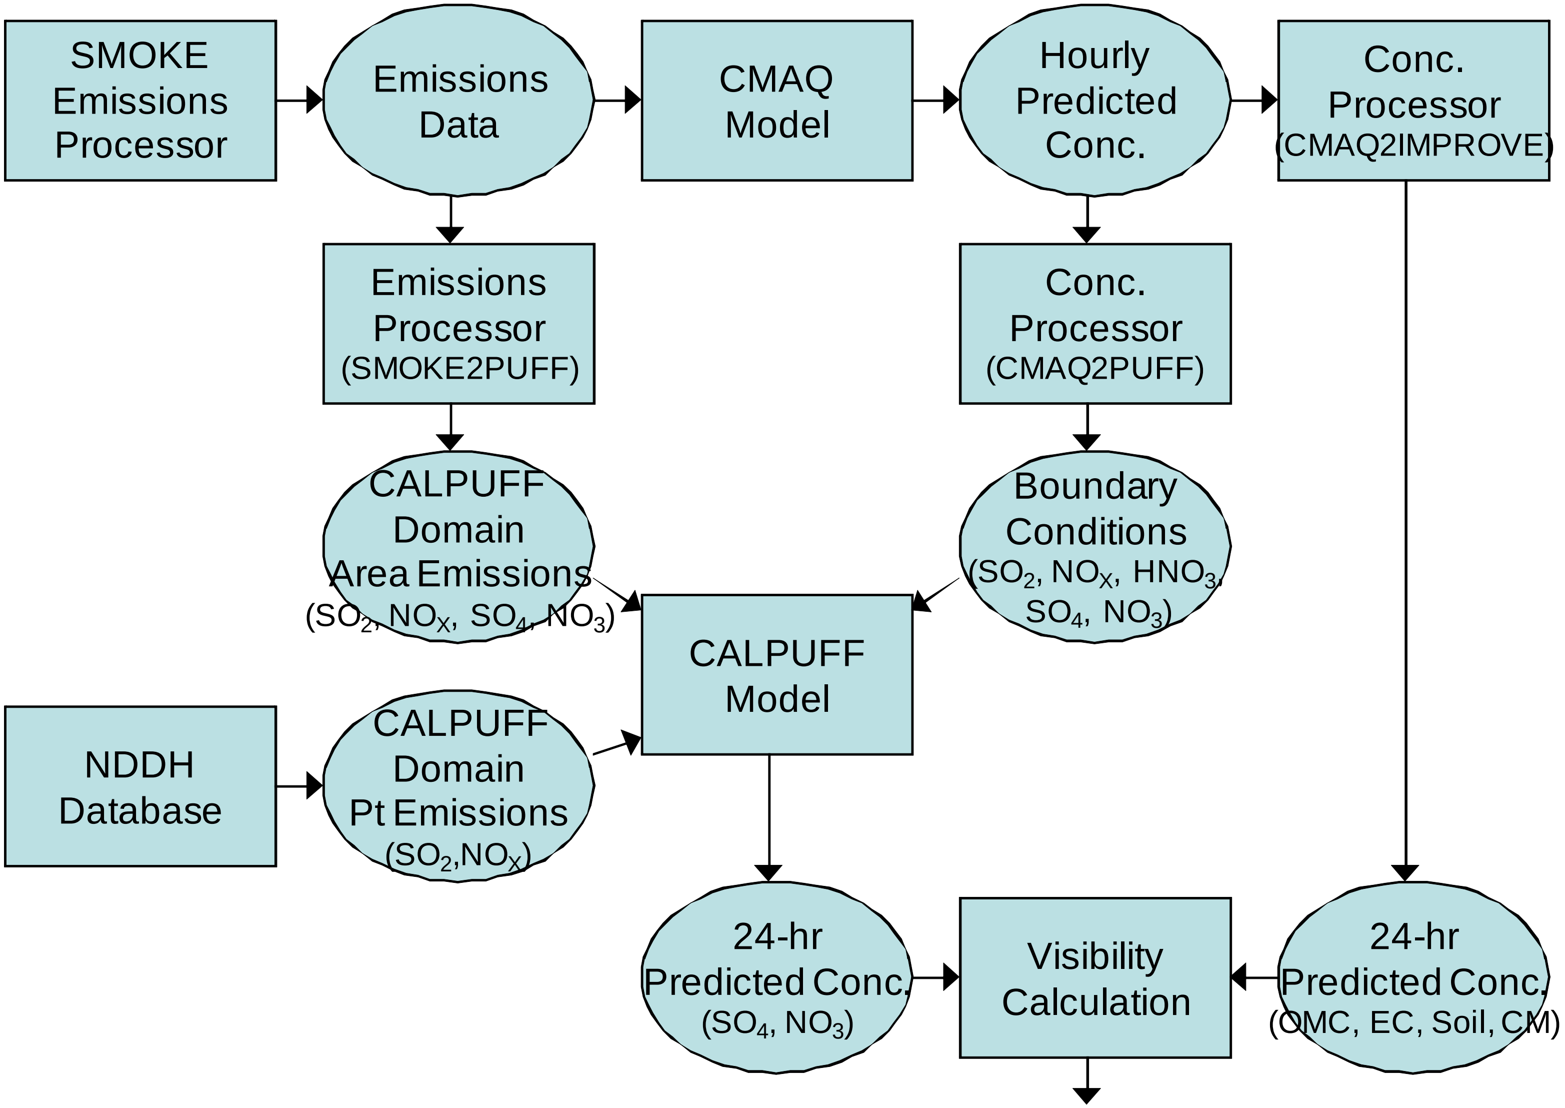
Figure 9-4
Interfacing of CMAQ and CALPUFF Modeling Systems



The versions of CALPUFF and associated programs which the NDDoH will utilize for regional haze modeling are summarized in Table 3-2.

Table 3-2
CALPUFF System Versions Applicable For Regional Haze Modeling

Program	**Version**	**Level**
CALMET	5.8	70623
CALPUFF	5.8	70623
POSTUTIL	1.56	70627
CALPOST	5.6394	70622

Specifics of the NDDoH plan for projecting future visibility are outlined in Section 4.

3.2 Normalizing Hybrid Model RRF to WRAP CMAQ RRF

Based on initial performance testing conducted by NDDoH, the hybrid CMAQ-CALPUFF modeling system performs well in replicating observed concentrations of SO_4 and NO_3 (see Appendix A). However, performance regarding sensitivity to changes in emissions appears less robust, with CMAQ-CALPUFF overstating future case nitrate formation compared to predictions obtained by WRAP using CMAQ alone. For this reason, the NDDoH is proposing to modify the methodology for projection of future visibility by normalizing or standardizing the hybrid CMAQ-CALPUFF RRF to the CMAQ RRF obtained by WRAP, for species SO_4 and NO_3. This normalized approach can be expressed:

$$\text{RRF}^{i,k} = \text{WRAP CMAQ RRF}^{i} \; \frac{\text{Hybrid Model production RRF}^{i,k}}{\text{Hybrid Model CMAQ emulation RRF}^{i,k}} \qquad (3\text{-}1)$$

where

RRF^{i} represents the EPA default relative response factor for species i (specific days for PLAN02d and PRP18a,

$\text{RRF}^{i,k}$ represents the relative response factor for species i and NDDoH scenario k,

> Hybrid Model production RRF represents the result from the weight of evidence modeling step (see Sections 4.4, 4.5),
>
> Hybrid Model CMAQ emulation RRF represents the result from the CMAQ emulation modeling step (see Section 4.6)

Note that the production RRF varies for each weight of evidence scenario, while the CMAQ emulation RRF remains constant for all weight of evidence scenarios. This is because all weight of evidence scenarios are normalized to the single (EPA default) modeling scenario conducted by WRAP

By standardizing or normalizing RRF's to the default CMAQ values obtained by WRAP, this approach acknowledges the sophistication of CMAQ chemistry compared to CALPUFF chemistry, especially the CMAQ sensitivity to changes in emissions. But the approach also retains the benefits of CALPUFF in providing better definition of point sources, plumes, and receptors. As discussed earlier, CMAQ-CALPUFF integration allows the NDDoH to explore future visibility impact from various local weight of evidence options which were not included in WRAP modeling. All weight of evidence scenario CMAQ-CALPUFF RRF's will be normalized to the WRAP CMAQ default RRF.

As indicated in Equation 3-1, the normalization scheme requires an RRF based on hybrid CMAQ-CALPUFF emulation of the WRAP CMAQ default configuration. CALPUFF inputs must be set so that the CMAQ-CALPUFF run replicates WRAP CMAQ as closely as possible. Though it is acknowledged that CALPUFF cannot reproduce the CMAQ chemistry, the configuration of emissions and receptors in CALPUFF can be adjusted to more closely emulate the WRAP CMAQ configuration. Software will be developed to allocate all point source emissions to a CALPUFF 36-km area source grid. The CALPUFF "effective height" (plume height) and "initial sigma z" area source input parameters will be used to assign point source emissions to discrete vertical "layers" which are consistent with WRAP CMAQ layers. Effective height will be based on stack height plus plume rise as calculated in the software.

Receptor resolution in WRAP CMAQ is limited to the average concentration in the 36-km surface grid cell volume containing the Class I area IMPROVE site. To emulate in CALPUFF, the predicted concentration will reflect the average over a uniform receptor grid placed within the CALPUFF area-source 36-km grid cell containing the IMPROVE site. Receptors will be spaced at 3 km for a total of 12 x 12 or 144 receptors for each Class I area. Elevation for each receptor will reflect the value used for the CALPUFF area-source grid cell.

Note that no changes to CALMET inputs (and thus the meteorological data set) are required for the emulation scenario. The ammonia background concentrations (emulation scenario) used with POSTUTIL will be derived from CMAQ output, which includes the ammonia species. Hourly ammonia concentrations will be taken from the CMAQ grid cells containing the North Dakota IMPROVE monitoring sites.

WRAP CMAQ RRF's (specific day option) are provided in Table 3-3.

Table 3-3
WRAP CMAQ RRF
(Specific Day Option)

	TRSU Worst D	**TRSU Best D**	**Lost Worst D**	**Lost Best D**
SO_4	0.92	1.02	0.91	1.02
NO_3	0.92	0.93	0.96	0.89
OMC	1.01	1.01	1.05	1.01
EC	0.72	0.78	0.73	0.74
Soil	1.13	1.08	1.11	0.96
CM	1	1	1	1

An example may clarify the normalization process. If, for 20% worst days at TRSU, one obtains an SO_4 RRF of 0.95 from the hybrid model production modeling step (call it weight of evidence scenario 1), and an SO_4 RRF of 0.99 from the hybrid model CMAQ emulation modeling step, the resultant final RRF for SO_4 becomes 0.92(0.95/0.99) or 0.88. In other words, instead of relying on the WRAP RRF of 0.92 to project future SO_4 concentratons, the RRF value has been "corrected" to 0.88 based on assumptions in the weight of evidence scenario 1, and the difference in treatment of emissions/receptors in CMAQ vs. hybrid modeling systems.

4 Detailed Visibility Projection Plan

1. Obtain/prepare CMAQ-related data from WRAP/RMC.

    a. Obtain CMAQ 36-km hourly concentration output files for BASE02b, PLAN02d, and PRP18a modeling cases (also for updated PRP18a cases when available). These data will be used to set SO_2-SO_4-NO_X-HNO_3-NO_3 boundary conditions for CALPUFF, and provide direct estimates of OMC, EC, Soil, and CM for calculation of visibility.

    b. Obtain CMAQ (SMOKE) 36-km gridded area source emissions data (annual) used for cases BASE02b, PLAN02d, and PRP18a modeling cases (also for updated PRP18a cases when available). These data will be used to apportion area source emissions for CALPUFF modeling.

    c. Develop/implement software to convert CMAQ hourly output for SO_2-SO_4-NO_x-

HNO_3-NO_3 to hourly boundary condition input for CALPUFF. Conversion procedure will focus on CMAQ output for grid cells in vicinity of perimeter of NDDoH CALPUFF domain.

   d. Develop/implement software to extract CMAQ hourly output concentrations for OMC, EC, Soil, and CM for grid cells containing TRNP and Lostwood IMPROVE monitors. These concentrations will be used directly in calculation of daily light extinction for these Class I areas (recall that CALPUFF simulation will provide SO_4 and NO_3 species only).

   e. Establish 36 km CALPUFF grid structure for area source emissions. This 36 km area source grid will be aligned with the basic NDDoH CALMET 3 km meteorological/computational grid.

   f. Develop/implement software/procedure to apportion CMAQ 36-km gridded (area source) annual emissions data to CALPUFF 36-km grid cells for species NO_2-NO-NO_3-SO_2-SO_4. The software must account for the use of different Lambert projections in CMAQ and CALPUFF coordinate systems. Also, the CMAQ NO and NO_2 species must be combined to form the NO_X species used by CALPUFF.

2. Review five-year base period (2000-2004) IMPROVE monitoring data to determine 20 % worst/best days at TRNP South Unit and Lostwood NWA Class I areas.

   a. Obtain raw IMPROVE data containing daily deciview for each Class I area from "TSS" web site (http://vista.cira.colostate.edu/tss/) for 2000-2004. For each Class I area and each year, rank days from highest to lowest deciview.

   b. Based on ranked daily deciview, determine 20% worst and 20% best visibility days for each year for each Class I area. Before determining 20% worst and 20% best days, eliminate any days with missing data for extinction calculation.

   c. Optional (weight of evidence) - Examine species composition and met. data for worst days in order to estimate primary source of emissions. Develop/implement objective criteria to discard each 20% worst day (for each year) where primary contribution to total deciview comes from sources over which the NDDoH has no regulatory control (e.g., natural emission source). Determine whether appropriate to substitute for discarded days from remaining ranked pool. Use adjusted inventory of 20% worst days to calculate average deciview, below. Note that this optional screening is not intended to apply to Canadian emissions, as a more direct method for discounting impact of those emissions is proposed (see Section 5).

3. Conduct a performance evaluation of the CMAQ-CALPUFF hybrid modeling system for SO_4 and NO_3 using 2002 meteorology, 2002 emissions, and 2002 IMPROVE observations.

   a. Use WRAP CMAQ hourly output for SO_2-SO_4-NO_X-HNO_3-NO_3 to set hourly boundary conditions for CALPUFF. CMAQ hourly output will be drawn from WRAP Case BASE02b, which is consistent with the scenario WRAP is using to test CMAQ performance.

b. Develop local emissions inventory for SO_2 and NO_X point sources located within the NDDoH CALPUFF domain. Inventory will be based on emissions for Year 2002. Point source data, with exception of oil and gas related sources, will be taken from the NDDoH modeling database, State of Montana, and Canada. Source data for oil and gas related emissions will be taken from the NDDoH / Oil and Gas Division's joint database. Actual emission rates, annual tons per operating hour, will be used for major sources. If time permits, application of seasonal emissions profiles will also be considered. Where CEM's data is available, the NDDoH may consider use of hourly emission rates.

c. Develop local emissions inventory for SO_2-SO_4-NO_X-NO_3 area sources located within the NDDoH CALPUFF domain. Area source data will be based on the WRAP area source inventory for 2002. CMAQ (SMOKE) 36-km gridded data for case BASE02b, apportioned to CALPUFF 36-km grid structure, will constitute the area source inventory. State quarterly emissions data from the "TSS" web site (http://vista.cira.colostate.edu/tss/) for case BASE02b will be used to apply quarterly (seasonal) profiles to the annual WRAP data. Source categories to be included in the area source inventory were outlined in Table 3-1.

d. Apply CALPUFF modeling system (CALMET-CALPUFF-POSTUTIL-CALPOST) for SO_2-SO_4-NO_X-NO_3 source inventories and boundary conditions as outlined above. Execution of the CALPUFF modeling system will be based on the NDDoH BART visibility modeling protocol[12] and the following additional input conditions:

    i. Apply modeling system for Year 2002 emissions/meteorology, only.
    ii. Specify receptors for TRNP South Unit and Lostwood NWA IMPROVE monitor locations, only (two receptors).
    iii. CALPUFF emission factors will be used to facilitate sources for which temporal emission profiles have been applied.
    iv. Apply the ammonia limiting method using POSTUTIL.

e. Prepare statistical summary of hybrid system performance for sulfate and nitrate. Statistics will be based on EPA *Guidance on the Use of Models and Other Analyses for Demonstrating Attainment of Air Quality Goals for Ozone, PM2.5, and Regional Haze*[13] (Section 18). Assessment of performance will focus on accuracy for 20% worst day average, and on the sensitivity of the modeling system to respond to changes in emissions.

---

[12] See Supra note 11

[13] See Supra note 6

f. Changes to CALMET-CALPUFF inputs, such as the configuration of emission inventories, which may improve performance and are scientifically defensible will be considered. Effectiveness of these changes will be addressed in a follow-up performance evaluation (i.e., repeat Steps d and e, above).

Note that NDDoH has conducted a preliminary performance evaluation, consistent with the procedure outlined above, which is described in Appendix A of this document.

4. Conduct RRF base period (2000-2004) production modeling for SO_4 and NO_3 using hybrid CMAQ-CALPUFF modeling system with 2002 meteorology.

   a. Use WRAP CMAQ hourly output for SO_2-SO_4-NO_X-HNO_3-NO_3 to set boundary conditions for CALPUFF. CMAQ hourly output for setting CALPUFF base period boundary conditions will be drawn from WRAP Case PLAN02d, which represents a composite emission scenario for the period 2000-2004.

   b. Develop local emissions inventory for SO_2 and NO_X point sources located within the NDDoH CALPUFF domain. Using the 2002 inventory developed for the performance evaluation (2b, above), edit emission rates to reflect average of annual emissions for 2000-2004 (use of unedited 2002 values for oil and gas related sources and other smaller sources may be adequate). WRAP has suggested monthly scaling of emissions[14]. If time permits, consider application of temporal emission profile to larger sources, where applicable (e.g., EGU's, agricultural facilities).

   c. Develop local emissions inventory for SO_2-SO_4-NO_X-NO_3 area sources located within the NDDoH CALPUFF domain. Area source data will be based on the WRAP area source inventory for the base period, 2000-2004. CMAQ (SMOKE) 36-km gridded data for case PLAN02d, apportioned to CALPUFF 36-km grid structure, will constitute the area source inventory. State quarterly emissions data from "TSS" web site (case PLAN02d) may be used to apply quarterly (seasonal) profiles to the annual WRAP data. Source categories to be included in the area source inventory were outlined in Table 3-1.

   d. Apply CALPUFF modeling system (CALMET-CALPUFF-POSTUTIL) for SO_2-SO_4-NO_X-NO_3 source inventories and boundary conditions as outlined above. Execution of the CALPUFF modeling system will be based on the NDDoH BART visibility modeling protocol and the following additional input conditions:

      i. Changes to CALMET-CALPUFF input settings (if any) established in performance evaluation.
      ii. Apply modeling system for year 2002 meteorology, only.

---

[14] See Supra note 2

   iii. Specify receptors for TRNP South Unit and Lostwood NWA IMPROVE monitor locations. For consistency with EPA guidance[15], additional receptors will be included to accommodate receptor averaging (accounts for possible inaccuracy of plume placement by the model) at both sites. A 3 x 3 grid of receptors, at 5 km spacing, will be centered on the IMPROVE monitor location.
   iv. CALPUFF emission factors will be used to facilitate sources for which temporal emission profiles have been applied.
   v. Apply the ammonia limiting method using POSTUTIL with hourly background values. Note that, if modeled scenario involves discounting the impact of Canadian sources (see Section 5), the 3-step ammonia limiting method must be applied to properly account for scavenging of ammonia by Canadian source emissions.

5. Conduct RRF future period (2018) production modeling for SO_4 and NO_3 using CMAQ-CALPUFF hybrid modeling system with 2002 meteorology.

   a. Use WRAP CMAQ hourly output for SO_2-SO_4-NO_X-HNO_3-NO_3 to set boundary conditions for CALPUFF. CMAQ hourly output for setting CALPUFF future period boundary conditions will be drawn from WRAP case PRP18a, which represents the preliminary projected emission scenario for 2018.

   b. Develop local emissions inventory for SO_2 and NO_X point sources located within the NDDoH CALPUFF domain. Using the 2002 inventory developed for RRF base period modeling (4b, above), annual emission rates / stack parameters will be edited to reflect expected changes by 2018 (use of unedited 2002 values for oil and gas related sources and other smaller sources may be appropriate). Point sources which have received or are likely to receive North Dakota (Montana, Canada?) air quality permits subsequent to 2004 will be added to the inventory. Sources which have shut down or are likely to shut down subsequent to 2004 and prior to 2018 will be deleted. For BART-applicable point sources, the NDDoH preferred BART control scenario will be used to develop 2018 annual emission rates and stack parameters (i.e., until BART control strategies are final). Temporal emission scaling will be applied as in the baseline point source inventory.

   c. Develop local emissions inventory for SO_2-SO_4-NO_X-NO_3 area sources located within the NDDoH CALPUFF domain. Area source data will be based on the WRAP area source inventory for the future period 2018. CMAQ (SMOKE) 36-km gridded data for case PRP18a, apportioned to CALPUFF 36-km grid structure, will constitute the area source inventory. State quarterly emissions data from “TSS” web site (case PRP18a) may be used to apply quarterly (seasonal) resolution to the annual WRAP data. Source categories to be included in the area source inventory were outlined in Table 3-1.

---

[15] See Supra note 6

d. Apply CALPUFF modeling system (CALMET/CALPUFF/POSTUTIL) for SO_2-SO_4-NO_X-NO_3 source inventories and boundary conditions as outlined above. Execution of the CALPUFF modeling system will be based on the NDDoH BART visibility modeling protocol and the following additional input conditions:

   i. Changes to CALMET/CALPUFF input settings (if any) established in performance evaluation.
   ii. Apply modeling system for year 2002 meteorology, only.
   iii. Specify receptors for TRNP South Unit and Lostwood NWA IMPROVE monitor locations. For consistency with EPA guidance[16], additional receptors will be included to accommodate receptor averaging (accounts for possible inaccuracy of plume placement by the model) at both sites. A 3 x 3 grid of receptors, at 5 km spacing, will be centered on the IMPROVE monitor location.
   iv. CALPUFF emission factors will be used to facilitate sources for which temporal emission profiles have been applied.
   v. Apply the ammonia limiting method using POSTUTIL with hourly background values. Note that, if modeled scenario involves discounting the impact of Canadian sources (see Section 5), the 3-step ammonia limiting method must be applied to properly account for scavenging of ammonia by Canadian source emissions.

e. Revise future case modeling (repeat 5a, 5c, and 5d) using WRAP CMAQ output representing updates to case PRP18a, when available.

f. Optional (weight of evidence) - To discount the effect of Canadian sources on compliance with visibility goals, delete all Canadian sources from the CALPUFF future emissions inventory before applying model (see discussion *The Impact of International Sources on North Dakota Class I Areas* in Section 5).

6. Conduct CMAQ emulation modeling needed to implement the normalization step described in Section 3.2, using CMAQ-CALPUFF hybrid modeling system with 2002 meteorology. (Note that CMAQ emulation modeling is conducted only once, with the same result used for any weight of evidence option).

   a. Modify the base and future period emissions inventories developed in above Steps 4 and 5 as follows:

      i. Reallocate point source emissions to area sources consistent with CALPUFF 36-km area source grid structure.
      ii. Use CALPUFF area-source “release height” and “initial sigma z” input parameters to configure all area sources (including those just created from point sources) in discrete “layers” consistent with WRAP CMAQ layers.

---

[16] See Supra note 6

        iii. No modification necessary for boundary conditions (boundary condition resolution already 36 km).

    b. Apply CALPUFF modeling system (CALMET-CALPUFF-POSTUTIL) for emission inventories and boundary conditions as outlined above, for both base and future period scenarios. Execution of the CALPUFF modeling system will be based on the NDDoH BART visibility modeling protocol and the following additional input conditions:

        i. Changes to CALMET/CALPUFF input settings (if any) established in performance evaluation.
        ii. Apply modeling system for year 2002 meteorology, only.
        iii. Use uniform receptor grid spaced to fill the CALPUFF 36-km (area source) grid cell containing the TRNP South Unit and grid cell containing the Lostwood NWA IMPROVE monitor locations. Receptors will be spaced at 3 km for a total of 12x12 or 144 receptors for each Class I area.
        iv. CALPUFF emission factors will be used to facilitate sources for which temporal emission profiles have been applied.
        v. Apply the ammonia limiting method using POSTUTIL with WRAP CMAQ hourly background values.

7. Develop SO_4 and NO_3 relative response factors (RRF) using CMAQ emulation scenario modeling results. (Note that CMAQ emulation RRF's are developed only once, and the same values are used for any weight of evidence option.)

    a. Extract CALPUFF daily (24-hour) predicted concentrations for the days consistent with the 20% worst days identified in IMPROVE monitoring data for 2002. Calculate the average of the daily SO_4 and NO_3 predictions for these days, for both baseline and future period scenarios. Repeat procedure for each Class I area.

    b. Calculate 20% worst day RRF's for each species (SO_4, and NO_3) as the ratio of the future average worst-day prediction to the baseline average worst-day prediction. Repeat for each Class I area.

    c. Repeat a, b, above, for 20% best days.

8. Develop final relative response factors using baseline and future scenario production modeling results.

    a. Extract CALPUFF daily (24-hour) predicted concentrations for the days consistent with the 20% worst days identified in IMPROVE monitoring data for 2002. Calculate the average of the daily SO_4 and NO_3 predictions for these days, for each scenario. Repeat procedure for each Class I area.

    b. Calculate 20% worst day RRF's for SO_4 and NO_3 species as the ratio of the future average worst-day prediction to the baseline average worst-day prediction. Repeat for each Class I area.

c. Use these RRF's, the CMAQ emulation RRF's from item7b, and the WRAP CMAQ RRF's from Table 3-3 to calculate the final RRF's for SO_4 and NO_3, using Equation 3-1. Repeat for each Class I area

d. Repeat a, b, and c, above, for 20% best days.

e. For OMC, EC, Soil, and CM species, take final RRF's from WRAP CMAQ modeling, as provided in Table 3-3.

f. For sea salt (SS), assume RRF of 1.0 for worst-days/best-days for both Class I areas.

9. Apply final RRF's to baseline monitoring data (2000-2004) to project future visibility for each Class I area .

   a. Apply species-specific RRF's to 20% worst baseline monitored days in year 2000 to project future concentrations for each species for each day (the same species-specific RRF's are used for each day). Repeat for years 2001 through 2004.

   b. Using the projected future concentrations for 20% worst days in year 2000, calculate light extinction (using new IMPROVE equation) and convert to deciview for each day. Repeat for years 2001 through 2004.

   c. Calculate average worst-day future deciview from projected daily future deciview (7b), for each year (2000-2004). Then, calculate future five-year average worst-day deciview.

   d. Repeat a, b, and c, above, for 20% best baseline monitored days.

   e. Optional (weight of evidence) - Using the species-specific projections from items 8c and 8e, calculate five-year average future light extinction for each species for 20% worst days (to accommodate glide path goals for individual species).

10. Determine status with respect to 2018 visibility goals.

   a. Compare five-year average projected future deciview for worst days (item 9c) with five-year average monitored baseline deciview for worst days (WRAP TSS), for each Class I area, to determine status with respect to visibility goals.

   b. Compare five-year average projected future deciview for best days (item 9d) with five-year average monitored baseline deciview for best days (WRAP TSS), for each Class I area, to determine whether visibility has deteriorated.

c. Optional (weight of evidence) - Compare five-year average projected future light extinction for each species for worst days (item 9e) with five-year average monitored baseline extinction for each species for worst days (WRAP TSS) to determine status with respect to visibility goals for individual species.

5 The Impact of International Sources on North Dakota Class I Areas

5.1 Proposed Approach

In the process of analyzing progress with respect to visibility goals, it will be necessary for NDDoH to address the impact of Canadian sources north of the International border. One method, as part of a weight of evidence demonstration, would be to discount the effect of Canadian sources (over which the State has no regulatory control). This could be accomplished by eliminating the contribution of Canadian sources to baseline monitoring data used for visibility projections, eliminating Canadian sources from the modeled inventories used to develop RRF's, and developing an adjusted glide path for future visibility goals.

Recall that EPA guidance[17] provides that RRF's are developed by comparing the future average predicted concentration for 20% worst days (best days) to the baseline average predicted concentration for 20% worst days (best days), for each species. The species-specific RRF's are then applied to species-specific baseline monitored concentrations for each 20% worst day (best day), for each baseline year, to project corresponding future values. Finally, these future daily concentrations are converted to light extinction, then deciview, and averaged over all worst (best) days to project future deciview. This approach is incorporated in the NDDoH visibility projection plan (Section 4).

To discount the effect of Canadian sources, the RRF's are adjusted in the modeling process, and a modified glide path is developed.. As discussed in Section 3, the projection of future concentration can be expressed:

$$X^{i,j}_{of} = X^{i,j}_{ob}\,(RRF^{i}) = X^{i,j}_{ob}\,(\overline{X}^{i}_{pf}/\overline{X}^{i}_{pb}) \qquad (5\text{-}1)$$

where

$X^{i,j}_{of}$ represents projected **o**bserved **f**uture concentration for species i on day j (each of 20% worst days for each baseline year),

$X^{i,j}_{ob}$ represents **o**bserved **b**aseline (IMPROVE data) concentration for species i on day j (each of 20% worst days for each baseline year),

---

[17] See Supra note 6

$\bar{X}^{i}_{pf}$ represents average **p**redicted **f**uture concentration for species i (average of 20% worst days),

$\bar{X}^{i}_{pb}$ represents average **p**redicted **b**aseline concentration for species i (average of 20% worst days),

RRF^{i} represents the relative response factor for species i.

To discount the effect of Canadian emissions, the impact of Canadian sources is removed from Equation 5-1 variables, which provides

$$X^{i,j}_{of(us)} = X^{i,j}_{ob(us)} \left(\bar{X}^{i}_{pf(us)} / \bar{X}^{i}_{pb(us)}\right) \qquad (5\text{-}2)$$

where

(us) represents the Equation 5-1 variable with the impact of Canadian sources removed (impact of US sources and natural background, only)

Thus, baseline US observations which exclude the impact of Canadian sources, and future and baseline modeling results which exclude the impact of Canadian sources, would be required to project future US concentrations. While baseline and future modeled inventories can be easily adjusted to remove Canadian sources, adjustment of baseline observations to exclude Canadian source impact could be technically difficult.

It is reasonable instead to consider a modeling solution for the estimation of adjusted baseline concentrations. A factor representing the ratio of modeled impact of “all baseline sources less Canadian sources” to “all baseline sources” could be applied to adjust the observed baseline, as follows:

$$X^{i,j}_{ob(us)} = X^{i,j}_{ob} \left(\bar{X}^{i}_{pb(us)} / \bar{X}^{i}_{pb}\right) \qquad (5\text{-}3)$$

Substituting Equation (5-3) into Equation (5-2) provides

$$X^{i,j}_{of(us)} = X^{i,j}_{ob} \left(\bar{X}^{i}_{pb(us)} / \bar{X}^{i}_{pb}\right) \left(\bar{X}^{i}_{pf(us)} / \bar{X}^{i}_{pb(us)}\right) \qquad (5\text{-}4)$$

Finally, Equation (5-4) reduces to

$$X^{i,j}_{of(us)} = X^{i,j}_{ob} \left(\bar{X}^{i}_{pf(us)} / \bar{X}^{i}_{pb}\right) \qquad (5\text{-}5)$$

So Equation 5-5 provides a modeling solution for projecting future concentrations without the impact of Canadian sources. The adjusted RRF’s ($\bar{X}^{i}_{pf(us)} / \bar{X}^{i}_{pb}$) would be inserted in the visibility projection plan item 8b to project future concentrations for each species for each day. Effectively, this approach is implemented by including Canadian sources in the baseline modeled inventory, and excluding Canadian sources from the future modeled inventory (i.e., the weight of evidence option included as modeling plan item 5f).

To complete the source apportionment process, the impact of Canadian emissions must also be removed from the glide path used to assess visibility improvement progress. The revised glide path would be based on Equation 5-3, which provides a baseline starting point without the effect of Canadian emissions. The adjusted species-specific glide path is illustrated in Figure 5-1, for a case where Canadian emissions comprise one-half of total observed concentrations for sulfate.

One caveat associated with the use of the adjusted glide path is that the impact of US-only emissions will not be consistent with 2018 IMPROVE monitoring data (which will reflect the total impact of all sources). If the 2018 IMPROVE data are to be used to monitor visibility progress with respect to the adjusted 2018 goal, the impact of 2018 Canadian emissions will first have to be subtracted from the monitored observations.

The NDDoH proposes to apply the adjusted RRF's and glide path for 20% worst days only, as the impact of Canadian sources is not likely to be problematic in meeting visibility goals for best days. Because hybrid modeling will be applied only for S and N chemistry, the RRF adjustment would apply only to sulfate and nitrate species.

Note that other methods have been suggested for discounting the effect of international sources on visibility improvement progress. CENRAP has proposed several options for discounting the impact of international sources[18]. Montana has suggested an adjusted glide path where the impact of international sources is added onto the 2064 natural background, rather than subtracted from the baseline. Effectively, the Montana approach produces the same result as the procedure suggested here.

5.2 Illustration

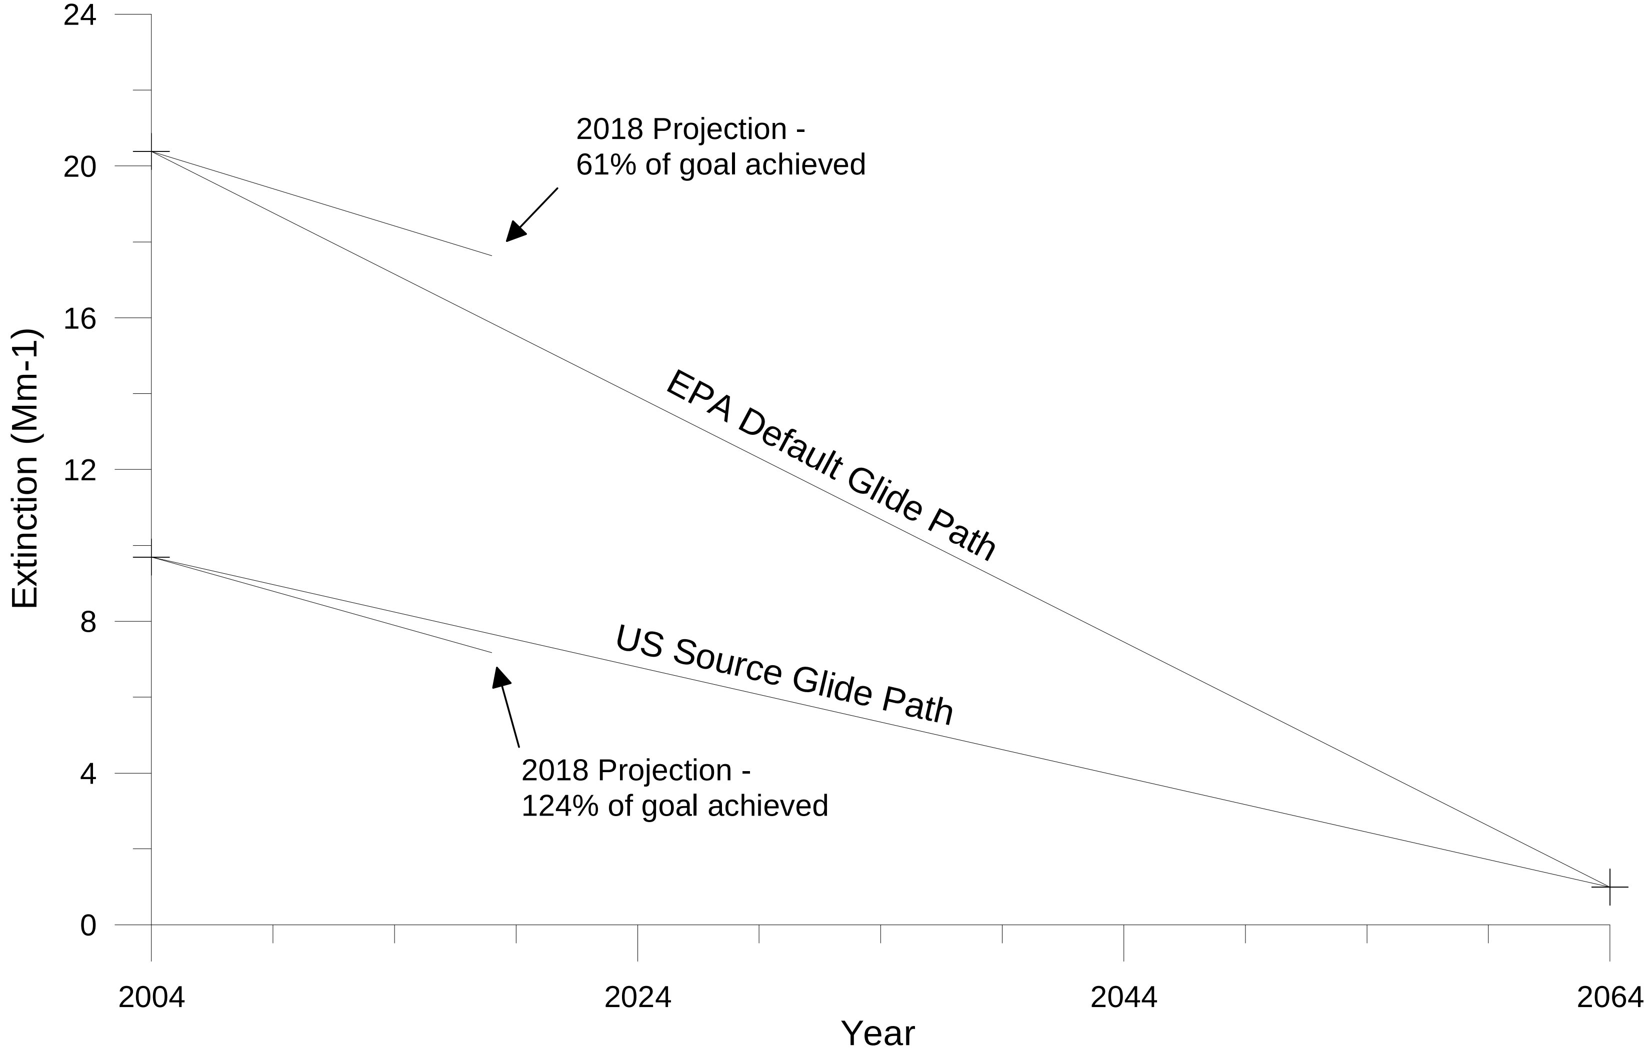
A species-specific illustration may clarify the proposed approach. Consider a hypothetical US Class I area where Canadian emissions contribute one-half of the average observed sulfate concentration for 20% worst days. For this illustration, it is assumed there are only two worst-case monitored days. It is also assumed that impact of US sources (plus natural sources) will be 25% lower in 2018 compared to the baseline, and that the inventory/impact of Canadian sources remains unchanged between the baseline and 2018. Finally, to implement the new IMPROVE equation, values for $f_s(RH)$, $f_l(RH)$, and conversion from sulfate to ammonium sulfate are assigned as 2.7, 2.1, and 1.375, respectively. (For simplification, this illustration does not include WRAP CMAQ normalization.)

First, consider what happens if no adjustment is made, and the impact of Canadian sources

---

[18] CENRAP, 2007. CENRAP Policy Oversight Group (POG) - Summary of PM Source Apportionment Modeling and 2018 Projection Approaches. Power Point presentation, Joint Workgroup Meeting, Kansas City, Missouri, March 7, 2007.

Figure 5-1
Illustration of Visibility Improvement Using EPA Default Glide Path and US Source Adjusted Glide Path for Sulfate



remains in the IMPROVE baseline observations, and the modeled baseline and future emission inventories (future projection based on Equation 5-1):

1) Examination of IMPROVE monitor data for this Class I area reveals that May 30 and July 10 are the two worst 20% visibility days in 2002. The observed concentration of sulfate on May 30 is 2.5 ug/m3, and the observed concentration of sulfate on July 10 is 2 ug/m3.

2) Generate EPA default glide path for this Class I area (Figure 5-1). Species-specific starting point for this glide path is determined by converting observed baseline sulfate concentrations for 20% worst days (in this case 2.5 ug/m3 and 2.0 ug/m3) to light extinction (new IMPROVE equation), then averaging over all worst case days. This provides a value of 20.38 Mm^{-1}. The 2064 endpoint for this path is the natural background, which for sulfate is assumed at 1.0 Mm^{-1}.

3) Baseline and future emission inventories are developed which include all US and Canadian sources. The CALPUFF/CMAQ modeling system is executed for the baseline inventory and the future inventory.

4) Modeling results for May 30 show a baseline predicted sulfate concentration of 2.8 ug/m3, and a future predicted sulfate concentration of 2.45 ug/m3. Results for July 10 indicate a baseline predicted sulfate concentration of 2.4 ug/m3, and a future predicted sulfate concentration of 2.1 ug/m3. Note that these results are consistent with the assumptions, above.

5) To develop the RRF for worst-day sulfate, the average future prediction is divided by the average baseline prediction as follows:

$$RRF = ((2.45+2.1)/2) / ((2.8+2.4)/2) = 0.875$$

6) The RRF is applied to sulfate observations for worst-case baseline days to project future worst-case sulfate concentrations:

May 30 $2.5 (0.875) = 2.19$ ug/m^3
July 10 $2.0 (0.875) = 1.75$ ug/m^3

7) Using the new IMPROVE equation, projected sulfate concentrations are converted to light extinction, then averaged over all worst-case days. This provides an average projected extinction of 17.63 Mm^{-1}.

8) Finally, the average projected future light extinction is compared with the glide path goal. This is illustrated in Figure 5-1.

Now, the exercise is repeated using the suggested approach for discounting impact of Canadian sources (future projection based on Equation 5-5).

1) Examination of IMPROVE monitor data for a hypothetical Class I area reveals that May 30

and July 10 are the two worst 20% visibility days in 2002. The observed concentration of sulfate on May 30 is 2.5 ug/m3, and the observed concentration of sulfate on July 10 is 2.0 ug/m3.

2) Develop adjusted glide path using Equation 5-3 (Figure 5-1). Species-specific baseline starting point for this glide path is developed by applying Equation 3 to 20% worst day sulfate concentrations, then converting concentration to light extinction, and averaging over all worst case days. For this illustration, the baseline value is 9.69 Mm^{-1}. Again, the path terminates in 2064 at natural background, which is assumed at 1.0 Mm^{-1} for sulfate.

3) A baseline emission inventory is developed which includes all US and Canadian sources. A future emission inventory is developed which includes all US sources, but no Canadian sources. The CALPUFF/CMAQ modeling system is executed for the baseline inventory and the future inventory.

4) Modeling results for May 30 show a baseline predicted sulfate concentration of 2.8 ug/m3, and a future predicted sulfate concentration of 1.05 ug/m3. Results for July 10 indicate a baseline predicted sulfate concentration of 2.4 ug/m3, and a future predicted sulfate concentration of 0.9 ug/m3. Note that these results are consistent with illustration assumptions.

5) To develop the RRF for worst-day sulfate, the average future prediction is divided by the average baseline prediction as follows:

$$RRF = ((1.05+0.9)/2) / ((2.8+2.4)/2) = 0.375$$

6) The RRF is applied to sulfate observations for worst-case baseline days to project future worst-case sulfate concentrations:

May 30 $2.5 (0.375) = 0.94$ ug/m^3
July 10 $2.0 (0.375) = 0.75 ug/m^3$

7) Using the new IMPROVE equation, projected sulfate concentrations are converted to light extinction, then averaged over all worst-case days. This provides an average projected extinction of 7.18 Mm^{-1}.

8) Finally, the average projected future light extinction is compared with the adjusted glide path goal. This is illustrated in Figure 5-1.

As indicated in Figure 5-1, with the EPA default method including all sources, 61% of the 2018 visibility goal is achieved. With the alternate approach excluding Canadian source impact, 124% of the 2018 goal is achieved.

Note that values used in this illustration for observed and modeled sulfate concentrations are completely hypothetical. The assumed 2064 natural background for sulfate, 1.0 Mm^{-1}, is consistent with values posted on the TSS web site for North Dakota Class I areas. However, other natural background values have been suggested[19].

6 Weight of Evidence Options

The NDDoH will complete the default visibility projection plan as detailed in Section 4. But the Regional Haze Rule[20] specifies that the SIP may be based, in part, on evidence apart from results of the default projection methodology. For example, the analysis could logically be modified to discount the impact of visibility-affecting emission sources over which the NDDoH has no regulatory control.

Options which could be considered in the analysis of visibility goals include:

- Discounting the impact of Canadian source visibility-affecting emission sources (discussed in Section 5 and included in the Visibility Projection Plan as optional item 5f).

- Discard certain worst-case monitored days, before projecting future visibility, if it can be determined that primary species affecting light extinction on these days cannot be controlled by NDDoH. This approach is included as a “weight of evidence” option in the Visibility Projection Plan (item 2c).

- Use of species-specific visibility progress goals. This approach has been suggested by WRAP[21], and is incorporated in the Visibility Projection Plan as “weight of evidence” options (items 2f, 9e, and 10c).

- Basing 20% worst visibility days for determining RRF’s on baseline model results rather than IMPROVE monitor data. This may be justified because neither CMAQ nor CALPUFF perform well on a “paired-in-time” basis. The resultant RRF’s would still be applied to worst case IMPROVE days to project future visibility.

The above list is preliminary and not necessarily complete. The process or results of the visibility projection analysis may suggest other weight of evidence options the NDDoH will want to pursue.

7 CALHAZE Software

The NDDoH is developing software (CALHAZE) to automate the analysis of IMPROVE baseline monitoring data, the development of RRF's, and the projection of future visibility. To establish baseline monitored conditions, the software will access IMPROVE data downloaded from the "VIEWS" web site. To develop RRF's, the software will operate on the CALPUFF (POSTUTIL) hourly output files from baseline and future modeled scenarios. The new IMPROVE equation, along with weight of evidence options noted above, will be incorporated in the software.

This software will be made available for public review. In order to validate it's accuracy, CALHAZE output values for baseline conditions and default RRF's have been successfully cross checked with data on the WRAP "TSS" web site.

Appendix A
Hybrid CMAQ-CALPUFF Performance Evaluation

The North Dakota Department of Health (NDDoH) has conducted a limited operational evaluation to assess performance of the hybrid CMAQ-CALPUFF modeling system. The focus of the evaluation was to assess performance in reproducing observed concentrations of sulfate and nitrate at IMPROVE monitoring sites in North Dakota. These sites include the Theodore Roosevelt National Park South Unit (TRSU) and the Lostwood Wilderness Area. Alternative input options which might improve performance were also explored. To the extent applicable, the performance evaluation followed EPA guidance for Regional Haze modeling analyses[22].

Evaluation of performance was based on the plan outlined in Section 4.3 of the modeling protocol. WRAP CMAQ hourly concentration output (SO_2-SO_4-NO_X-HNO_3-NO_3) for Case BASE02B was used to set hourly boundary conditions for CALPUFF. The emissions inventory (SO_2-NO_X) for the point source category was developed using data from the NDDoH emissions database for 2002, and sources were configured as conventional point sources in CALPUFF. This inventory included point sources located in adjacent parts of South Dakota, Montana, and Canada, which are included in the NDDoH CALPUFF domain (see Figure 1-2). This inventory also included SO_2 emissions associated with oil and gas production facilities (treaters and flares) in North Dakota, which did not appear to be accounted for in the WRAP inventory for BASE02B. Emission rates for the point source inventory reflect actual emissions for Year 2002.

All other source categories (see Protocol Table 3-1) were treated as area sources in CALPUFF, and the emissions inventory (SO_2-SO_4-NO_X-NO_3) for these categories was based on WRAP CMAQ input (SMOKE output) for all sources other than point sources. Software was prepared and implemented to apportion the gridded SMOKE output emissions for BASE02B into a 36-km area source grid structure developed for the NDDoH CALPUFF domain, on a consistent spatial basis. Emission rates for this area source inventory reflect annual averages for the SMOKE data.

The CALPUFF modeling system (CALMET-CALPUFF-POSTUTIL-CALPOST) was applied for SO_2-SO_4-NO_X-NO_3 source inventories and boundary conditions as described above. For all other input conditions, execution of the CALPUFF modeling system was initially based on the

---

[22] EPA, 2007. Guidance on the Use of Models and Other Analyses for Demonstrating Attainment of Air Quality Goals for Ozone, PM2.5, and Regional Haze. Publication No. EPA 454/B-07-002, Office of Air Quality Planning and Standards, Research Triangle Park, NC 27711.

NDDoH BART visibility modeling protocol[23] using Year 2002 meteorology. Single receptors were placed at the TRNP and Lostwood IMPROVE sites. The ammonia limiting method was applied using POSTUTIL. Concurrent, monthly average ammonia data were taken from the NDDoH Beulah monitoring site.

After initial application of CALPUFF for the performance evaluation, it was concluded that certain scientifically-defensible adjustments to CALPUFF input conditions may improve performance for the hybrid modeling system, and should be investigated. Thus, the performance evaluation evolved into a suite of tests which are described below.

1) Test 1 - CALPUFF system executed with default input conditions, as outlined above. Air mass depth for boundary conditions was set to 2000 meters.

2) Test 2 - CALPUFF as in Test 1, but using CEMS 2002 hourly emissions data (SO_2, NO_X) for point sources, where available.

3) Test 3 - CALPUFF as in Test 1, but using WRAP MM5 12 km 2002 mesoscale data in CALMET, rather than the default NDDoH RUC 2002 mesoscale data.

4) Test 4 - CALPUFF as in Test 1, but increasing air mass depth for boundary conditions from 2000 to 3000 meters.

5) Test 5 - CALPUFF as in Test 1, but with addition of SO_4 and NO_3 emissions from point sources. (Previous tests excluded this component, because SO_4 and NO_3 emissions are not included in the NDDoH point source inventory. For Test 5, an SO_4-NO_3 emissions inventory was derived from SMOKE gridded output for the point source category, and configured as area sources for CALPUFF.)

6) Test 6 - CALPUFF as in Tests 4 and 5 (air mass depth = 3000 meters, SO_4 and NO_3 emissions from point sources included), but area sources configured as 4 groups to account for varying release heights, and Beulah hourly profile used for background NH_3 in POSTUTIL. (Area sources were configured as a single CALPUFF group in previous tests.)

7) Test 7 - CALPUFF as in Test 6, but Beulah hourly NH_3 profile doubled for Lostwood.

Results of the performance evaluation are summarized in Tables A-1 and A-2. Table A-1 compares predicted NO_3 and SO_4 concentrations to observed concentrations for both IMPROVE sites, while Table A-2 provides predicted-to-observed ratios. Note that both tables include a column labeled “CMAQ only”, which provides the original WRAP CMAQ results for Case BASE02B.

As shown in Tables A-1 and A-2, the three metrics selected to measure performance for this

---

[23] See Supra Note 11

evaluation are 90th percentile day concentration (24-hour average), average of 20% worst days concentration, and annual average concentration. The first two metrics were selected for consistency with the time scale that applies to regional haze modeling, i.e., average of the 20% worst or 20% best days. The third metric, annual average concentration, is a measure of the model's ability to accurately conserve total annual mass. The comparison between predicted and observed concentrations for the first two metrics is unpaired in time.

Results in Tables A-1 and A-2 indicate that the hybrid modeling system performed well, in general. Even for the default Test 1, predictions were well within a factor of two of observations. In most cases, the hybrid system predictions were closer to observations than predictions from CMAQ, alone. Table A-2 illustrates that the hybrid system slightly over-predicted observations for TRSU NO_3, and slightly under-predicted, otherwise.

A comparison of results for Tests 1 through 5 reveals very little difference in predictions. The implication is that the input changes reflected in Tests 2 through 5 did not add significant value to the predictions. The increased temporal resolution obtained by using the CEMS hourly emissions for applicable point sources (Test 2) provided no consistent improvement. Test 3 results suggest that the NDDoH RUC mesoscale data is consistent with the WRAP MM5 mesoscale data. Test 4 results indicate that CALPUFF is not very sensitive to boundary air mass depth. Even the addition of point source NO_3 and SO_4 emissions in Test 5 achieved no meaningful improvement in predictions, suggesting that sources configured as area sources in CALPUFF may have only a small contribution to the total prediction.

While the operational evaluation to compare predictions with observations was being conducted, the NDDoH also undertook a preliminary diagnostic evaluation[24] to assess the response of the hybrid modeling system to changes in NO_3 and SO_4 predictions. In response to significant reductions in both SO_2 and NO_X emissions, the NDDoH found that the hybrid system responded reasonably well with lower SO_4 predictions, but seemed to overstate NO_3 predictions for the reduced emission scenario. In fact, NO_3 concentrations actually increased under some assumptions, possibly an overreaction to the newly freed ammonia in the reduced SO_2 emissions scenario (SO_2 preferentially scavanges ammonia in the CALPUFF chemistry). This behavior was not seen in the WRAP CMAQ results for baseline versus future predictions.

To address the problematic NO_3 response, the NDDoH discussed the issue with Joe Scire (TRC)[25], a recognized CALPUFF expert in the regulatory modeling community. Mr. Scire indicated that TRC testing has shown that the NO_3 response may improve if hourly background ammonia is used rather than monthly average values. Also, Mr. Scire provided some insight on configuring area sources in CALPUFF to be more consistent with the area source treatment in CMAQ. This involves proper settings for the CALPUFF "release height" and "initial sigma z" input parameters for area sources. The NDDoH retested after incorporating Mr. Scire's

---

[24] See Supra note 22

[25] TRC, 2008. Telephone consultation with Joe Scire, May 29, 2008. Joe Scire, TRC Corporation, Lowell, MA 01854

suggestions, i.e., using hourly ammonia background and reconfigured area sources. Although the NO_3 response improved, predicted reductions were still not consistent with CMAQ.

As a result of the initial diagnostic performance testing, the NDDoH concluded that the use of hourly ammonia background concentrations is preferable to the use of monthly averages, and that CALPUFF inputs for area sources should be reconfigured. Additional operational evaluation tests (Tests 6 and 7) were thus conducted to determine how these changes would affect the comparison with observations. Test 6 was conducted by first assuming a boundary air mass depth of 3000 meters (Test 4) and accounting for NO_3 and SO_4 emissions from point sources (Test 5). Then area sources were configured as suggested by Scire, including the use of 4 area source groups to account for varying release heights for different source categories (as opposed to one group in Tests 1-5). Finally, Test 6 included use of the Beulah hourly ammonia profile in POSTUTIL.

Results of Test 6, as shown in Tables A-1 and A-2, indicate significantly improved performance with respect to TRSU NO_3, but worse performance for Lostwood NO_3. Results for SO_4 were not significantly affected. This tendency for conflicting results for TRSU and Lostwood NO_3 was also exhibited in Tests 1 through 5, and led the NDDoH to conclude that the Beulah data may not be representative of ammonia background for both TRSU and Lostwood. Moreover, the actual ammonia background affecting Lostwood may be significantly higher than the background affecting TRSU.

In Test 7, the NDDoH found that observational agreement for Lostwood NO_3 can be vastly improved if the ammonia hourly backgound values are approximately doubled (for Lostwood only). All other conditions for Test 7, including the ammonia background for TRSU, remain the same as in Test 6. NO_3 predictions for Test 7 in Tables A-1 and A-2 now show good agreement with observations at both TRSU and Lostwood.

Notice of Intent
To Amend the
State Implementation Plan
For Air Pollution Control
Relating to the Reduction of Regional Haze

North Dakota
Department of Health

will hold a public hearing to address proposed changes to the State Implementation Plan (SIP) for the Control of Air Pollution for the State of North Dakota which address Regional Haze in the Federal Class I areas.

Environmental Training Center
2639 East Main Avenue
Bismarck, ND
January 7, 2010
9:00 a.m. CST

A copy of the proposed SIP revision may be viewed at the Department's website at www.ndhealth.gov/AQ/RegionalHaze/. A copy of the proposed SIP revision may be obtained by writing to the North Dakota Department of Health, Division of Air Quality, 918 E Divide Avenue, Second Floor, Bismarck, ND 58501-1947 or calling (701)328-5188. Written comments may be submitted to the above address from December 8, 2009 through January 8, 2010. The SIP revision addresses requirements on sources to reduce regional haze (visibility impairment) in Theodore Roosevelt National Park (TRNP) and Lostwood Wilderness Area (LWA). The SIP revision includes a Permit to Construct for each of five electric utility steam generating plants which establishes limits for sulfur dioxide and nitrogen oxides that are intended to improve visibility impairment in TRNP and LWA.

The National Park Service and the U.S. Fish and Wildlife Service, Federal Land Managers for TRNP and LWA respectively, as well as the U.S. Forest Service have provided comments on the draft Regional Haze SIP revision. The comments and the Department's response to those comments are found in Appendix J.1 of the SIP revision. These documents may be accessed at the website listed above or by contacting the Department.

If you plan to attend the hearing and will need special facilities or assistance relating to a disability, please contact the Department of Health at the above address at least seven days prior to the hearing.

Re: Regional Haze SIP Revision

Dear Ms. Videtich:

Enclosed is a CD that contains North Dakota's draft State Implementation Plan (SIP) revision to address regional haze in the federal Class I areas. Also, enclosed is a public notice announcing a public hearing and comment period on the proposed SIP revision. We are providing these documents to you so that your staff can review them and provide any comments during the public comment period. The public comment period is scheduled from December 8, 2009 to January 8, 2010. A public hearing regarding the proposed SIP revision is scheduled for January 7, 2010 at the Department's Environmental Training Center at 2639 E. Main Ave., Bismarck, North Dakota at 9:00 a.m. CST.

We would like to note that only one facility in North Dakota is subject to the BART guidelines. This is the Coal Creek Station and it is not subject to the guidelines for sulfur dioxide emissions. When your staff provides comments, we ask that they provide a reference to applicable rule or law for any required changes to the SIP.

If you have any questions, please feel free to contact me or Tom Bachman of my staff at (701)328-5188.

Sincerely,

Re: Regional Haze State Implementation Plan Revision

Dear Ms. Silva:

The North Dakota Department of Health has developed a State Implementation Plan (SIP) revision to address the regional haze requirements of 40 CFR 51.308. The proposed SIP revision may be viewed at the office of the North Dakota Department of Health, 918 E. Divide Ave., 2nd Floor, Bismarck, North Dakota or at the Department's website at: www.ndhealth.gov/AQ/RegionalHaze/. A copy of the proposed SIP revision may be requested by writing the Department at the above address or by calling (701)328-5188. Also included is a notice announcing a public hearing that will be held to consider testimony regarding the proposed SIP revision. The hearing is scheduled for January 7, 2010. The Department welcomes any comments you or your staff may have regarding the SIP revision. All comments received by January 8, 2010 will be included as part of the hearing record. Written comments must be sent to the address listed above.

You are invited to attend and present testimony at the hearing. If you plan to attend the hearing and will need special facilities or assistance relating to a disability, please contact the North Dakota Department of Health at the above telephone number or address at least seven days prior to the hearing.

If you have any questions, please contact Tom Bachman of my staff at (701)328-5188.

Sincerely,

Terry O'Clair

Re: Regional Haze State Implementation Plan Revision

Dear Mr. Clark:

The North Dakota Department of Health has developed a State Implementation Plan (SIP) revision to address the regional haze requirements of 40 CFR 51.308. The proposed SIP revision may be viewed at the office of the North Dakota Department of Health, 918 E. Divide Ave., 2nd Floor, Bismarck, North Dakota or at the Department's website at: www.ndhealth.gov/AQ/RegionalHaze/. A copy of the proposed SIP revision may be requested by writing the Department at the above address or by calling (701)328-5188. Also included is a notice announcing a public hearing that will be held to consider testimony regarding the proposed SIP revision. The hearing is scheduled for January 7, 2010. The Department welcomes any comments you or your staff may have regarding the SIP revision. All comments received by January 8, 2010 will be included as part of the hearing record. Written comments must be sent to the address listed above.

You are invited to attend and present testimony at the hearing. If you plan to attend the hearing and will need special facilities or assistance relating to a disability, please contact the North Dakota Department of Health at the above telephone number or address at least seven days prior to the hearing.

If you have any questions, please contact Tom Bachman of my staff at (701)328-5188.

Sincerely,

Terry O'Clair

Re: Regional Haze State Implementation Plan Revision

Dear Ladies/Gentlemen:

The North Dakota Department of Health has developed a State Implementation Plan (SIP) revision to address the regional haze requirements of 40 CFR 51.308. The proposed SIP revision may be viewed at the office of the North Dakota Department of Health, 918 E. Divide Ave., 2nd Floor, Bismarck, North Dakota or at the Department's website at: www.ndhealth.gov/AQ/RegionalHaze/. A copy of the proposed SIP revision may be requested by writing the Department at the above address or by calling (701)328-5188. Also included is a notice announcing a public hearing that will be held to consider testimony regarding the proposed SIP revision. The hearing is scheduled for January 7, 2010. The Department welcomes any comments you or your staff may have regarding the SIP revision. All comments received by January 8, 2010 will be included as part of the hearing record. Written comments must be sent to the address listed above.

You are invited to attend and present testimony at the hearing. If you plan to attend the hearing and will need special facilities or assistance relating to a disability, please contact the North Dakota Department of Health at the above telephone number or address at least seven days prior to the hearing.

If you have any questions, please contact Tom Bachman of my staff at (701)328-5188.

Sincerely,

Terry O'Clair

State Health Department Schedules Public Hearing

BISMARCK, ND – The North Dakota Department of Health has scheduled a public hearing to address proposed changes to the North Dakota State Implementation Plan for the control of air pollution. The public hearing will be held Jan. 7, 2010, at 9 a.m. at the department's Environmental Training Center, 2639 E. Main, Bismarck, N.D.

The hearing will address the Department of Health's plan for reducing regional haze (visibility impairment) in Theodore Roosevelt National Park and the Lostwood National Wildlife Refuge Wilderness Area.

The public also may submit written comments regarding the changes by Jan. 8, 2010. The public is invited to direct their comments to Terry O'Clair, Division of Air Quality, North Dakota Department of Health, 918 E. Divide Ave., Bismarck, N.D. 58501-1947.

For more information, contact Tom Bachman, North Dakota Department of Health, at 701.328.5188.

If you have previously received a disarge in a Chapter 7 bankruptcy, this is t an attempt to collect a debt against u personally, but only an attempt to demine your intention concerning retain- this property.

ec 7, 14, 21, 2009) 1011529

NOTICE OF SALE
Civil No. 09-08-C-04891

Notice is hereby given that by virtue of judgment of foreclosure by the District ourt of the East Central Judicial District and for the County of Cass and State of orth Dakota, and entered and docketed the Office of the Clerk of said Court on ctober 19, 2009, in an action wherein ank of New York as Trustee for the Cerlcate Holders of CWALT 2004-J09 was aintiff and Joshua A. Deutsch; Sarah K. eutsch; Mortgage Electronic Registraɔn Systems, Inc., on behalf of Lender ecision One Mortgage Company, LLC.; orth Dakota State Tax Commissioner; CI Credit Services Inc.; North Dakota tate University; and any person in posɘssion were Defendants, in favor of aintiff and against the Defendants for e sum of $104,039.19, which judgment nd decree, among other things, direct e sale by me of the real property hereinter described, to satisfy the amount of aid judgment, with interest thereon and e costs and expenses of such sale, or o much thereof as the proceeds of said ale will satisfy; and by virtue of a writ isued to me out of the office of the Clerk of aid Court, I, Paul D. Laney, Sheriff of ass County, North Dakota, will sell the roperty described in the Judgment to the ighest bidder for cash at public auction t the front door of the Courthouse in the ity of Fargo in the County of Cass and tate of North Dakota, on December 30, 009, at the hour of 10:00 A.M. (CT), to atisfy the amount due, with interest hereon, and the costs and expenses of uch sale, or so much thereof as the proeeds of such sale will satisfy. The property to be sold is situated in the County of ass and State of North Dakota, and decribed as follows:

Lots Sixteen and Seventeen, in Block 'Aa" of Erskine's Addition to the City of argo, Situate in the County of Cass and he State of North Dakota, a/k/a 1004 9th Street South, Fargo, ND 58103.

IN TESTIMONY WHEREOF, I have ereunto set my hand and seal this 25th day of November, 2009.

Paul D. Laney
Sheriff of Cass County, North Dakota
By: Dean Fercho, Deputy
STATE OF NORTH DAKOTA
ss
County of Cass

On this 25th day of November, 2009, before me, a Notary Public in and for said County and State, personally appeared Dean Fercho, known to me to be the person who is described in, and whose name s subscribed to this instrument.

STATE OF NORTH DAKOTA
PUBLIC SERVICE COMMISSION

FirstLink
211 Designation
Application Case No. PU-09-713

NOTICE OF OPPORTUNITY FOR HEARING
November 25, 2009

The Federal Communications Commission (FCC) has designated the 211 dialing code to provide direct access to organizations providing community information and referral services that are currently not available through the 911 emergency code or the 311 police non-emergency code.

On September 24, 2003, the Commission designated the Mental Health Association in North Dakota (MHAND), as the user of the 211 dialing code in North Dakota.

On March 7, 2007, the Commission authorized MHAND to subcontract 211 operations within North Dakota. MHAND has been subcontracting with FirstLink for the provision of 211 operations in Cass County.

In its October 30, 2009 letter, MHAND notified the Commission that, due to lack of economic support, it must relinquish its designation as the 211 dialing code user.

On November 2, 2009, the Commission received a letter stating that effective October 30, 2009, FirstLink will temporarily provide 211 operations for North Dakota until a decision is made about 211's future.

On November 23, 2009, FirstLink filed a letter requesting designation as the 211 dialing code user for North Dakota.

The issues to be considered are:

1. Is any other entity interested in designation as the user of the 211 dial code in North Dakota?
2. Is the FirstLink's intended use of the 211 dial code in North Dakota consistent with the FCC intended use of that code?

Those interested are invited to comment in writing. Persons desiring a hearing must file a written request identifying their interest in the proceeding and the reasons for requesting a hearing. Comments and requests for hearing must be received by January 8, 2010. If deemed appropriate, the Commission can determine the matter without a hearing.

For more information contact the Public Service Commission, State Capitol, Bismarck, North Dakota 58505, 701-328-2400; or Relay North Dakota 1-800-366-6888 TTY. If you require any auxiliary aids or services, such as readers, signers, or Braille materials please notify the Commission.

Notice of Intent To Amend the State Implementation Plan For Air Pollution Control Relating to the Reduction of Regional Haze

North Dakota Department of Health will hold a public hearing to address proposed changes to the State Implementation Plan (SIP) for the Control of Air Pollution for the State of North Dakota which address Regional Haze in the Federal Class I areas.

Environmental Training Center
2639 East Main Avenue
Bismarck, ND
January 7, 2010
9:00 a.m. CST

A copy of the proposed SIP revision may be viewed at the Department's website at www.ndhealth.gov/AQ/RegionalHaze/. A copy of the proposed SIP revision may be obtained by writing to the North Dakota Department of Health, Division of Air Quality, 918 E Divide Avenue, Second Floor, Bismarck, ND 58501-1947 or calling (701)328-5188. Written comments may be submitted to the above address from December 8, 2009 through January 8, 2010. The SIP revision addresses requirements on sources to reduce regional haze (visibility impairment) in Theodore Roosevelt National Park (TRNP) and Lostwood Wilderness Area (LWA). The SIP revision includes a Permit to Construct for each of five electric utility steam generating plants which establishes limits for sulfur dioxide and nitrogen oxides that are intended to improve visibility impairment in TRNP and LWA.

National Park Service and the U.S. Fish and Wildlife Service, Federal Land Managers for TRNP and LWA respectively, as well as the U.S. Forest Service have provided comments on the draft Regional Haze SIP revision. The comments and the Department's response to those comments are found in Appendix J.1 of the SIP revision. These documents may be accessed at the website listed above or by contacting the Department.

If you plan to attend the hearing and will need special facilities or assistance relating to a disability, please contact the Department of Health at the above address at least seven days prior to the hearing.

Dated this 25th day of November 2009

Regional Haze SIP Hearing
January 7, 2010
9:00 a.m.

Good Morning. Welcome to the Environmental Training Center. First of all, thank you for challenging North Dakota's frigid air temperatures this morning to attend the hearing. My name is Terry O'Clair and I will be acting as hearing officer for this public hearing. It is approximately 9:05 a.m., January 7, 2010 in the North Dakota State Health Department's Environmental Training Center. This public hearing has been called for the purpose of allowing all interested individuals an opportunity to submit information concerning the Department's draft State Implementation Plan revision addressing Regional Haze. Information gathered at the hearing will be transmitted to the Department's Division of Air Quality for deliberation and final decision. The Department will not be responding to comments at this hearing. Comments received at the hearing will be considered with any written comments that are received and the Department will present its consideration of all comments in writing. You may request a copy of the written response and one will be provided to you.

This hearing is being taped and we ask everyone offering testimony to use the podium so that the tape will be of good quality for transcribing purposes. Please identify yourself for the record before you speak. Everyone present will be given an opportunity to speak. If you have a prepared statement, a written copy of the statement is appreciated.

A registration sheet has been placed next to the door. I ask that everyone present please sign the sheet before they leave.

Before we begin accepting testimony, I would like to add a point of clarification pertaining to the MDU Heskett Station Unit 2 addressed in Section 7.3.4 of the draft SIP. Prior to commencing the public comment period, the Department had received comments from EPA and the Federal Land Managers suggesting that the MDU Heskett Station Unit 2 was not exempt from the Best Available Retrofit Technology review. The Department agreed to reassess our determination. MDU agreed to remodel the Heskett Station Unit 2 in accordance with the EPA preferred model settings and the methodology suggested by the Federal Land Managers that combines all three units of the Theodore Roosevelt National Park for modeling purposes. The Department has reviewed the original modeling as well as the revised modeling submitted by MDU and concluded that Heskett Station Unit 2 is exempt from the BART process. The information has been submitted to the U.S. Environmental Protection Agency and the Federal Land Managers. The revised modeling is on the Department's web site at: www.ndhealth.gov/aq/regionalhaze. This document is formally incorporated into the hearing record.

Although the modeling demonstrated that the MDU Heskett Station was exempt from BART requirements, the Department conducted additional modeling to determine the impact on visibility if BART-like emissions control equipment were to be installed. This BART-like control equipment would reduce sulfur dioxide emissions by 95% and nitrogen oxides emissions by 40%. The results of that modeling indicate only a 0.009 deciview improvement at Theodore

Roosevelt National Park and only a 0.003 deciview improvement at Lostwood Wilderness Area during the most impaired days. The Department considers this amount of visibility improvement to be inconsequential.

At this point I open the hearing for testimony. *At this point there was no one interested in providing oral testimony and the hearing was left open for 10-15 minutes to allow incoming people to arrive due to the weather conditions.*

Closing

Thank you all for coming. All information gathered at the hearing will be provided to the Department of Health which is the decision-making body. The record will be held open for written comment until January 8, 2010. At this point I close the hearing on the State Health Department's proposed State Implementation Plan revision for Regional Haze. *The hearing was closed at 9:20 a.m.*

After closing the hearing Jim Kambeitz arrived and stated he was late due to car problems and expressed his interest in providing oral testimony. The hearing was reopened at 9:30 a.m. to allow Mr. Kambietz to give his testimony.

My name is James Kambeitz and I am an educator and teacher for 10 years and resident of North Dakota. I would like to represent the young in the State and I would like to push for stronger air quality controls given that our eight power plants have been mostly grandfathered in and they already emit higher emissions than most of the power plants in the United States. According to the Clean Air Act, we require that we have Class I air in national parks and this protects us from manmade pollution. There is haze coming from the coal plants; it has been photographed, I have photographed it and a lot of people have seen it. It has also been tested. We know that we are burning about 30 million tons of coal each year and this does affect us. So, I would like the Health Department to try to make stricter goals and to move us further along in the future toward cleaner air and protecting us. That small river valley basin for the Knife River and coming down the Missouri River is a very heavily, densely, industrialized river valley and people in North Dakota don't realize it. So, we get by with polluting a lot more than we really should under the Clean Air Act. I hope that we will review, revise and strengthen our air quality plan here in North Dakota for the young, for all of our health and for the economy. The jobs in North Dakota are 3 to 1 green jobs which are outdoing normal job growth in North Dakota. It is also where the jobs are happening, that is a Pew study that I am citing there. There are a lot of studies based on what the trends are going to be and what will help us in the State. Also, tourism must be considered here since it is such a large part of our economy. So many millions of dollars and our state tourism department is putting so much money in trying to promote more hunting and more people to visit our national parks. So, we really need to protect these natural resources for us, for our economy and for our children. I also think that people who are polluting, the power plants, need to be the ones held responsible for the pollution they are emitting instead of just the public and us paying for our health problems as a result. Thank you all for listening so politely and I am not against energy and not against the coal industry. I would just like it to diversify so that it can survive and market itself better in the future.

Mr. O'Clair stated that that is one of the things that regional haze is attempting to do is reduce emissions from some of the older facilities that may be causing visibility issues. Mr. O'Clair thanked Mr. Kambietz and stated that if he would like to provide comments in writing that they would be accepted until close of business Friday, January 8. Mr. O'Clair once again closed the hearing.

Certification of Public Hearing

Re: Implementation Plan for the Control of Air Pollution
for the State of North Dakota

Certification:

The undersigned certifies that the public hearing held by the North Dakota Department of Health on January 7, 2010, for the purpose of receiving and considering testimony and evidence bearing on the proposed revisions to the Implementation Plan for the Control of Air Pollution for the State of North Dakota was held in accordance with the notice required by Section 51.102 Public Hearings of the Requirements for Preparation, Adoption, and Submittal of Implementation Plans, Code of Federal Regulations, Title 40, Chapter I, Subchapter C, Part 51.

Date: January 7, 2010 Tom Bachman

Affidavit:

State of North Dakota

County of Burleigh

On the 7th day of January 2010 before me personally appeared Tom Bachman, who having been duly sworn, stated that to the best of his knowledge and belief the statements in the foregoing certification are true.

Subscribed and sworn to before me

My Commission Expires Oct. 18, 2014

Environmental Protection Agency

Comment 1: Purpose/Legal Authority, last paragraph, p. 3: We note that the Coyote Station Permit to Construct is contained in Appendix A not Appendix D. Please clarify.

Response: The reference will be clarified to indicate the Coyote Permit to Construct is in Appendix A.

Comment 2: Tables 6.3 and 6.4, pp. 41-42: The NO_x emissions inventory for 2018 has been changed from previous versions reviewed. Please explain this change. It appears the point source number was revised downward to include projected emissions reductions from the Coyote Station. If so, we note that the Coyote Permit to Construct doesn't require compliance with the revised NO_x limit until July 1, 2019. Therefore, it is not appropriate to include the reduction in the 2018 inventory.

Response: The installation of the separated overfire air will be completed by July 1, 2018 or earlier. Based on our experience with the M.R. Young Station, the effects in reducing emissions should be immediate. By the end of 2018, we believe the NO_x will be reduced to the level of the Permit to Construct. Since we are indicating the reductions that will be achieved by this SIP revision, we believe it is appropriate to include the reductions from Coyote.

Comment 3: Exclusion of Montana Dakota Utilities Heskett Unit No. 2, p. 66-68:

(A) Table 7.2 – This table will need to be revised to include updated 98th percentile visibility impact results based on approved modeling.

(B) We are in the process of reviewing MDU's December 17, 2009 revised modeling report. EPA will provide additional comments on this issue if the revised modeling fails to address our concerns. See comment #21 below for more detail.

Response:

(A) Agreed

(B) No response necessary. It is the Department's understanding that EPA agrees that Heskett Unit 2 is exempt from BART.

Comment 4: Section 7.4.2, Department BART Determinations, p. 69-77: The modeling to determine if each BART-eligible source has a significant impact on visibility was performed by NDDH using the CALPUFF model following EPA's Interagency Workgroup on Air Quality Modeling (IWAQM) Phase 2 Summary Report and Recommendations for Modeling Long Range Transport Impacts specified in the Guidelines for BART Determinations Under the Regional Haze Rule, 40 CFR Part 51, Appendix Y. However, NDDH conducted an alternative cumulative visibility modeling approach in the NO_x BART determinations for M.R. Young and Leland Olds because it believes single source modeling results "tend to be five to seven times larger" than results when the same source is combined with all other sources in a cumulative analysis (although for other pollutants that affect visibility - PM and SO_2 - it appears that the State used the single source method contained in the BART Guidelines). The basis for NDDH's belief is that the perceived change in visibility from controls on a single source is reduced when background contributions from other sources are included in the modeling.

EPA does not agree that the single source modeling under the BART Guidelines overstates the degree of visibility improvement from emission reductions at the source. The Clean Air Act establishes a National goal of eliminating man-made visibility impairment from all mandatory Class I Federal areas. Use of a clean background (*i.e.*, not considering other nearby sources) is consistent with the ultimate goal of the program to reach natural background conditions. Moreover, the consistent use of a clean background in BART evaluations in North Dakota and surrounding states will foster emission reductions that will speed achievement of natural background conditions, and will ensure equity among states in achieving this goal. The NDDH has already modeled the 98th percentile values using the BART Guidelines' methodology for evaluating visibility improvements from the various control options. These values need to be used when weighing the visibility benefit factor in the NO_x BART analyses.

In addition, North Dakota has noted elsewhere that "according to the Regional Haze Rule, the focus of visibility improvement demonstrations is the 20% worst visibility days, not the cleanest days." This statement is contradicted by several provisions in the Regional Haze Rule that call for assessment of both the most and least impaired days. See, *e.g.*, 40 CFR 51.308(d)(2), (f)(1), and (g)(3).

Response: The Clean Air Act in Section 169A(g)(2) states: "in determining best available retrofit technology the State (or the Administrator in determining emission limitations which reflect such technology) shall take into consideration the costs of compliance, the energy and nonair quality environmental impacts of compliance, any existing pollution control technology in use at the source, the remaining useful life of the source, **and the degree of improvement in visibility which may reasonably be anticipated to result from the use of such technology**;" [emphasis added]. We believe the cumulative modeling provides a much more accurate estimate **of the degree of improvement in visibility which may reasonably be anticipated to result from the use of SCR**.

The difference between cumulative and BART single-source modeling results starts with the logarithmic relationship between deciview and light extinction, which is based on the proven concept that an observer will detect visibility changes more easily in clean air than in dirty air. Deciview is related to light extinction using the equation

$$dv = 10 \text{ x } \ln(b_{ext} / 10)$$

where

dv = deciview

b_{ext} = light extinction in units of inverse mega-meters (Mm^{-1})

In BART single-source modeling, the incremental impact of the subject source is based on a background of natural visibility conditions only. In cumulative modeling, as conducted by WRAP, the incremental impact of the subject source is based on a background of natural visibility conditions plus the impact of a complete inventory of all other source emissions which affect visibility. Therefore, calculated delta-deciview for the subject source for the cumulative case will be lower than for the single-source case.

A simple hypothetical example can illustrate the difference in single-source and cumulative visibility modeling. Assume that a subject source is contributing 5 Mm^{-1} to total light extinction and that the natural visibility background is 20 Mm^{-1}. Under single-source modeling, delta-deciview for the subject source would be calculated:

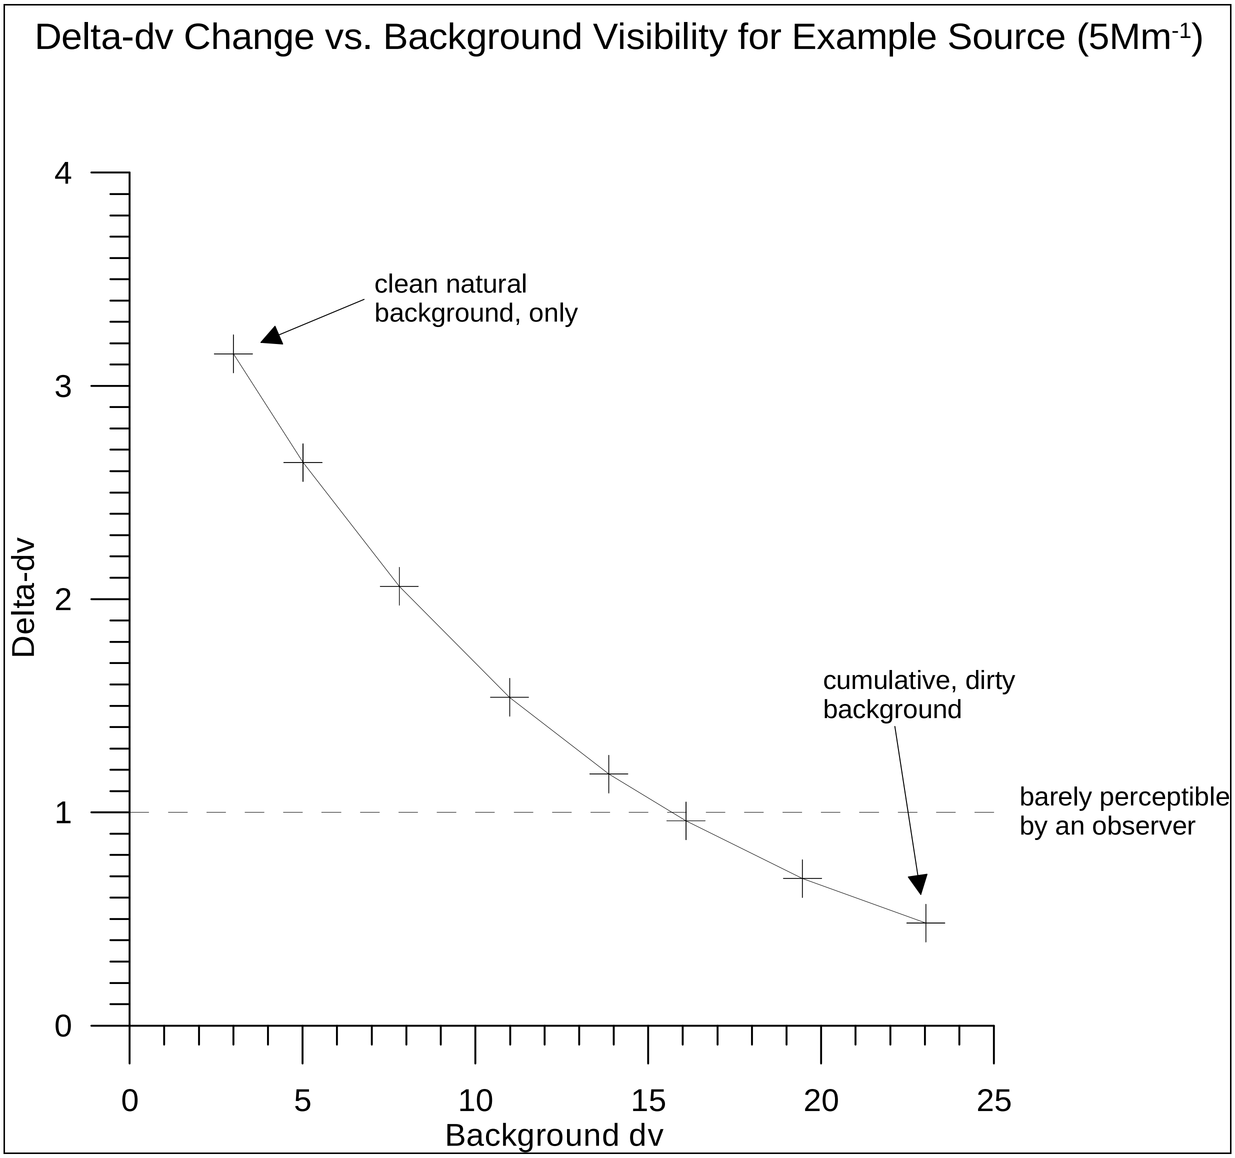
$$\text{delta-dv} = [10 \text{ x } \ln(25 / 10)] – [10 \text{ x } \ln(20 / 10)] = 9.16 – 6.93 = 2.23$$

WRAP and the NDDH have found that adding a complete emissions inventory in the cumulative modeling will typically result in a background more than double the natural visibility conditions. So to complete the example for the cumulative modeling case, we assume a background of 50 Mm^{-1} and the same subject source. Delta-deciview for the subject source would be calculated:

$$\text{delta-dv} = [10 \text{ x } \ln(55 / 10)] – [10 \text{ x } \ln(50 / 10)] = 17.05 – 16.09 = 0.96$$

Therefore, inclusion of the complete visibility-affecting emissions inventory in the cumulative modeling produces a smaller, but more realistic, observer-detected difference of 0.96 deciview from the subject source. In fact, for this example, the cumulative modeling result falls below the generally recognized observer-detectable threshold of about 1.0 deciview. Thus, the example illustrates that the impact of the subject source plume against a clean background would be much more noticeable to an observer than the impact of the same plume against the more realistic dirtier background. And, obviously, any change in visibility-affecting emissions from the subject source would have a smaller impact on the observer under the cumulative modeling scenario.

In the figure below, delta-deciview has been plotted for several background deciview levels, based on the subject source, above. The included background levels range from a clean natural background to a dirty background representing the cumulative effect of many visibility-affecting sources. The plot includes the two points calculated above. The plot illustrates the general dependency of the observed visibility change (delta-deciview) on the background level, and the fact that an observer’s perception of visibility change can vary greatly depending on the background deciview level. In fact, for this example, there is a factor of 6.6 difference in delta-deciview for the cleanest background compared with the dirtiest background (3.15 / 0.48 = 6.56).



To further illustrate the difference in single-source and cumulative visibility analyses, the NDDH conducted additional modeling using actual sources. For this illustration, the NDDH grouped the BART-applicable Coal Creek, Leland Olds, and Milton R Young Generating Stations (in North Dakota) as an effective single source. Single-source and cumulative modeling analyses were conducted to determine the incremental visibility improvement at Theodore Roosevelt National Park from the 3-source group, based on BART controls. Calpuff system versions 5.8, the new IMPROVE equation, annual average natural background, and consistent annual emission rates (for the three noted sources) were applied for both analyses. The 90th percentile visibility day from the single-source modeling results was used to emulate the 20% worst day average from the cumulative modeling results. (Given that the typical distribution of 20% worst day visibilities tends to be skewed toward the high end, the 90th percentile day may somewhat understate the 20% worst day average). Note that the post-BART emissions inventory for the cumulative analysis included changes only to the three sources referenced above.

Results of the NDDH modeling analyses are summarized in the table below. The modeling analyses discussed above are compared in the first two columns of results.

	20% Worst Day Avg. Cumulative Modeling	90th Percentile Day Single-Source Modeling	90th Percentile Day Single-Source Modeling Using 2005 ND BART Protocol
Baseline (dv)	16.954	6.552	5.583
Post-BART (dv)	16.493	5.641	3.288
Improvement (delta-dv)	0.461	0.911	2.295

As shown in the table, visibility improvement from the addition of BART controls to the three generating stations based on single-source modeling is about twice that found from cumulative modeling. These results are consistent with the hypothetical example discussed above.

Also shown in the table are results of a third modeling scenario, i.e., single-source modeling based on the North Dakota BART modeling protocol. Consistent with EPA recommendations at the time (2005), the North Dakota BART protocol specified the use of Calpuff Version 5.7, the old IMPROVE equation, and a natural background reflecting cleanest days. In addition, the protocol specified use of maximum 24-hour emission rates, per the BART Rule. As indicated in the table, use of this protocol resulted in a much greater "apparent" improvement in visibility, about a five-fold increase in the result from the cumulative modeling. This illustration, therefore, is another basis for the NDDH statement in the SIP that BART single-source modeling over predicts by a factor of 5 to 7.

All BART modeling conducted by the NDDH and industry was based on the North Dakota BART protocol. Given differences in the North Dakota BART protocol (compared to later protocols), combined with the logarithmic nature of the relationship between deciview and light extinction, it becomes clear that BART single-source modeling could have greatly overstated the more realistic results obtained from recent cumulative modeling for North Dakota.

Note that use of the ND BART single source modeling produces a visibility improvement at Theodore Roosevelt National Park (2.295 dv) which achieves compliance with the uniform rate of progress goal (2.3 dv as discussed in Section 5 of the North Dakota SIP). If one was to accept the premise that these single-source modeling results are realistic, it would logically follow that North Dakota has met the uniform rate of progress based on BART controls for the three modeled sources, and that the need to address additional (non-BART) visibility-affecting emissions reductions in North Dakota is therefore less compelling.

The 20% worst-day average metric from cumulative modeling and the 90th percentile day metric from single-source modeling have been compared in this illustration as they constitute a comparable moment of the annual distribution of daily visibility predictions. Obviously, the 98th percentile day metric from single-source modeling would provide an even greater exaggeration of actual visibility change than the 90th percentile, in the context of the 20% worst-day average metric required to measure progress with respect to visibility goals under the regional haze rule.

The Leland Olds Station and M.R. Young Station are not subject to the BART Guideline (see response to Comment 43.B regarding the M.R. Young Station). In the BART Guideline (40 CFR 51, Appendix Y, Section I.H) it states “For sources other than 750 MW power plants, however, states retain the discretion to adopt approaches that differ from the guidelines.” The Department is exercising this discretion for these sources since the cost of SCR is very high on a dollar per ton basis and on incremental cost basis. Therefore, the cumulative visibility modeling results were weighted significantly in our decision not to require SCR.

Comment 5: SO_2 BART section, p. 71: The SO_2 BART determination for Stanton Station Unit 1 may result in too high a limit when burning Powder River Basin (PRB) coal. Please see our Comment #49 below for more detail.

Response: See response to Comment 49.

Comment 6: NO_x BART section, p. 73: We do not agree that SNCR satisfies the BART requirements for Leland Olds Unit 2 and M.R. Young Units 1 & 2. See our comments below on the related BART determinations.

Response: See response to Comments 22-25, 27, 31-33.

Comment 7: Section 8.5.1, Hybrid Modeling System, pp. 95-96: The NDDH utilized a hybrid modeling approach for determining the status of its Class I areas with respect to the rate of progress visibility goals. This approach involved nesting a local NDDH CALPUFF modeling domain within the WRAP National CMAQ domain, and applying the CALPUFF model in a retrospective sense to more realistically define plume geometry for local point sources. The hybrid modeling results were used in a weight of evidence analysis to evaluate the effect of emission sources located outside of North Dakota. Please note that the last version of this modeling protocol to be reviewed by EPA was a draft dated April 2007 (*i.e.*, we never received the final October 2008 version for review). As modeling science has improved, there have been a number of technical changes in the CALPUFF modeling system and EPA/FLM recommended default settings since NDDH proposed the CMAQ/CALPUFF hybrid modeling approach in 2007. In the Reasonable Progress modeling, the hybrid CALPUFF/CAMx modeling results were adjusted based on IMPROVE monitoring data, and it is not clear whether the use of these obsolete settings affected the weight of evidence factors or the Reasonable Progress demonstration. The settings NDDH used in the CALPUFF model within the hybrid modeling system would not be considered technically sound if contained in a regulatory modeling protocol for a future project. However, in this instance it does not appear to have made a difference since North Dakota is not able to meet the uniform rate of progress with either the WRAP analysis or NDDH's hybrid modeling system.

Response: EPA was sent the final October 2008 version of the modeling protocol. The protocol was sent by email from Steve Weber to Kevin Golden on October 6, 2008 (see attached copy of this email).

As discussed in Section 8.5.6, the NDDH ultimately applied its hybrid modeling system to adjust or add value to WRAP CMAQ visibility modeling results, rather than as a stand-alone tool for absolute visibility projections. The adjustment is based on a correction where hybrid CMAQ-CALPUFF model output is involved in both the numerator and denominator of the correction factor (fraction). Therefore, the effects of the NDDH alternative CALMET/CALPUFF technical settings (reflected in both numerator and denominator model output) would have largely "cancelled out" when the correction factor was applied. In fact, had the CALMET/CALPUFF technical settings been reset to be completely consistent with EPA recommendations, it is not likely the correction factor would have meaningfully changed.

Comment 8: Section 8.6.1, Hybrid CMAQ-CALPUFF Performance Evaluation, p. 132, 1st paragraph, 1st sentence: Model performance was tested for the 90th percentile days. In addition, NDDH needs to compare performance on the 98th percentile day consistent with the BART metric.

Response: Section 8.6.1 has been revised to include hybrid model performance for the 98th percentile day.

Comment 9: Section 8.6.2.3, Apportionment by Source Group, pp. 146-153: We note that focus was on North Dakota EGUs and boundary condition groups due to their relatively "small" and "large" contributions, respectively. Since NDDH needs to be looking at what is within its control, North Dakota EGUs become the largest contributors. We also note that North Dakota's NO_3 percent contribution in 2018 actually increases at LWA (Table 8.16, p. 152), so it appears that there may be additional NO_x sources within North Dakota's control that can be addressed. This increase may be related to increased oil and gas development in the area.

Response: As we noted in the SIP, we believe WRAP has overestimated the increase in NO_x emissions from oil and gas production activity in North Dakota. Although the percent contribution for the North Dakota sources increases in 2018, the actual contribution ($\mu g/m^3$) and the total contribution of all sources decreases by 2018. The only area which increases the actual contribution to nitrates ($\mu g/m^3$) in LWA is Canada (see WRAP TSS).

Comment 10: Section 8.6.2.5, Conclusions, pp. 156-157: NDDH concludes that while the addition of proposed BART controls will substantially decrease the visibility impact of North Dakota EGUs, these EGUs comprise only a small component of total 20% worst day impacts at TRNP and LWA. The text needs to also note that during periods when EGU emissions are transported into the Class I areas, the proposed BART reductions will significantly improve visibility. This can be demonstrated by referencing the peak day and 98th percentile CALPUFF results for each EGU.

<u>Response</u>: Even though modeling demonstrated that North Dakota EGUs comprise only a small component of general 20% worst-day average impact at TRNP and LWA, the NDDH acknowledges that BART reductions from these EGUs likely resulted in substantial visibility improvement on certain worst days with favorable meteorology. Language has been added to the conclusions in Section 8.6.2.5 to facilitate this acknowledgement.

<u>Comment 11</u>: Section 9.5.1, Step 1, pp. 177-181: We have several comments related to this section. First, please note that the Q/D approach does not work for sources like Oil & Gas where the emissions are spread out over large areas, but cumulatively the emissions and impacts from these sources can be significant. In addition, the narrative needs to acknowledge the potential impact of primary PM if emissions are large. Next, please note that the reference to the BART Guidelines under the Q/D discussion is not necessarily applicable for Reasonable Progress purposes. Lastly, it appears that Heskett Station Unit 2 was omitted from the sources reviewed in Table 9.4. Please clarify.

<u>Response</u>: The Q/D analysis can work for certain oil and gas facilities such as compressor stations or natural gas processing plants. We agree it would not work well for oil production or development facilities. This has been added to Section 9.5.5.

With regard to oil and gas production and development emissions of particulate matter, both the Department and WRAP agree that emissions will be very small. The only emissions that are not covered in other source categories would be fugitive emissions from road and well pad construction. These emissions are short duration (a few days or less) and are subject to the fugitive dust control requirements in NDAC 33-15-17. As can be seen from Table 6.1 and 6.3, road dust emissions, which includes emissions associated with oil and oil development and production, are not expected to increase from 2002 rates. We do not anticipate any significant increase in visibility degradation due to PM emissions from oil and gas production activities.

Regarding the Q/D discussion for exemption from BART, we believe this is highly relevant. When the visibility impact of a source is so small it can be exempted from BART, additional controls under reasonable progress are likely not to be cost effective on a dollar per deciview basis.

Heskett Unit 2 will be added to Table 9.4.

<u>Comment 12</u>: Section 9.5.1, Table 9.8, p. 184:

(A) As noted in our August 12, 2009 preliminary comments on the WRAP's May 18, 2009 Draft *Supplementary Information for Four-Factor Analyses for Selected Individual Facilities in North Dakota,* the reliance on a 1982 NSPS analysis for Claus Sulfur Recovery Units raises questions regarding why newer data could not be utilized. Advancements in energy efficient technology and heat transfer media may affect tail gas treatment unit operational needs. Current data should be available and may indicate lower energy and steam usage. Please verify that these concerns with the WRAP report were not carried over into the North Dakota SIP.

(B) There appear to be numerous NO_x controls available at costs similar to, or less than, those selected under BART, raising the question of why Antelope Valley and Coyote Station warranted a decision by NDDH that NO_x controls carry excessive costs. Since NDDH has already determined BART controls - similar to the control options analyzed for the Reasonable Progress units - to be cost effective and to provide visibility improvement, it is unclear how similar controls on the EGUs at Antelope Valley and Coyote Station would not be justified.

(C) Some average cost effectiveness figures are lower for control options that provide greater reductions, *e.g.*, Low NO_x Burners (LNB)+SNCR at Antelope Valley Units 1 & 2 and Low-Emission Combustion (LEC) Retrofit at Tioga Gas Plant's five 1920 hp reciprocating engines. The clear advantage of these options warrants further consideration by NDDH.

(D) The estimated cost effectiveness of control options for Tioga Gas Plant's rebuilt engines (2350 hp) appears to be inaccurate since reductions are underestimated for add-on controls. Despite emission reductions achieved during rebuild, the percent control efficiency should not differ that much from engines that are not currently operating at peak performance. It appears that NDDH relied on the WRAP's May 18, 2009 Draft *Supplementary Information for Four-Factor Analyses for Selected Individual Facilities in North Dakota*, which assumed that "air-to-fuel ratio adjustments, ignition timing retarding, and LEC retrofit would not achieve further emission reductions since the estimated emission reductions for these measures are less than the reductions which appear to have already been achieved." However, the above reductions should have been assumed on top of reductions which appear to have been achieved through rebuild. In addition, the WRAP report indicates that SCR reduces emissions from reciprocating engines by 90%; therefore, NDDH needs to explain its use of 80% for the 1920 hp engines and 50% for the 2350 hp engines. Using an inappropriately low control efficiency will result in a biased high cost effectiveness of a control option.

Response:

(A) EPA has provided no evidence to support their claim that advancements have been made in energy efficiency and heat transfer media. The NDDH believes the cost estimate represents a reasonable representation of the cost of a tail gas clean up unit. Any savings in energy, including steam, will have a minor impact on the annualized costs. We believe the estimate is within the ±30% range of accuracy of the EPA Air Pollution Control Cost Manual recommended by EPA.

(B) In the BART determinations, visibility impacts were given very little weight for SO_2 and NO_x because of the inaccuracy of the BART single source modeling unless the control option had a high cost effectiveness or incremental cost. If cost effectiveness or incremental cost was high, we considered the cumulative type modeling. Had visibility impacts been weighed more heavily, some of the referenced selected BART technologies would not have been chosen. In evaluating reasonable progress, we evaluated the cost on a dollar per ton basis and the amount of visibility improvement (as you have correctly pointed out that the Department can consider). For Antelope Valley Station, all controls will improve visibility in the most impaired days by 0.01 deciviews or less. For the Coyote Station, the improvement is 0.04 deciviews or less and for the Tioga Gas Plant it is 0.05 deciviews or less. The maximum improvement for these facilities combined is 0.11 deciviews at LWA and 0.03 deciviews at TRNP during the most impaired days. To achieve this minute amount of improvement would require an annual cost of 68 million dollars. The Department has concluded that the trivial amount of visibility improvement does not warrant such costs. As pointed out in the SIP, other control options will improve visibility on the most impaired days even less.

(C) The Department did evaluate LNB+SNCR at the Antelope Valley Station and LEC Retrofit at the Tioga Gas Plant (see Tables 9.8 and 9.9). The cost on a dollar per deciview basis and the trivial amount of visibility improvement does not warrant requiring these controls.

(D) In establishing a baseline for calculating the cost effectiveness of a control option, we used the emissions for the 2350 Hp engines after they were refurbished since it represents current normal operations for these engines and anticipated future emissions. You cannot ignore money that has been spent to reduce emissions before the reasonable progress analysis began or was ever envisioned. To do so would provide an artificially low cost for additional reductions and is contrary to the methodology for making BART and BACT determinations.

The WRAP Report dated May 18, 2009 lists an efficiency of 80-90% in Table 4-1 for the 1920 Hp engines. Table 4-2 lists an efficiency of 80%. The NDDH has determined that 80% is more reasonable for emission limits that must include startup, shutdown and malfunctions. For the 2350 Hp engines, the WRAP Report lists a range of 33-67% (see Table 4-2). The NDDH determined the middle of the range was appropriate for these engines that are emitting 70% less NO_x than the engines that were not refurbished.

Comment 13: Section 9.5.1, Step 3, p. 183-185: Visibility improvement is not one of the four Reasonable Progress statutory factors (cost of compliance, time necessary for compliance, energy/non-air quality environmental impacts of compliance, and remaining useful life of any potentially affected sources), but the State has the flexibility to consider it in decision-making. The State selected a number of emission units for potential Reasonable Progress controls; however, as shown in Table 9.9, NDDH may have eliminated these from consideration due to a perceived small visibility improvement attributed to each control measure. The cost effectiveness ($/ton) for reducing emissions at a number of the sources considered for Reasonable Progress controls is similar to the cost effectiveness that NDDH considered appropriate for control at the BART sources. Thus, it is reasonable to consider controlling these sources as well. The relatively low visibility benefit for controlling an individual unit should not be a major factor to consider when selecting Reasonable Progress measures; given the ultimate purpose of the Regional Haze program, cumulative effects across sources need to be considered. In addition, since NDDH has chosen to rely heavily on visibility improvement for its decisions on Reasonable Progress controls, we consider it important to include the 98th percentile day results in addition to the 20% worst days results. In our view, since the 98th percentile day results are used in determining BART, and NDDH has chosen to rely on visibility improvement in determining Reasonable Progress controls, it makes sense to include the 98th percentile day results under Reasonable Progress to supplement the 20% worst days results.

Response: The purpose of the Regional Haze program is to improve visibility. The Department considers this purpose in its decision making process. EPA, in this comment, acknowledges that a state has the right to consider the amount of visibility improvement. Because of the purpose of the rule, visibility improvement has weighed heavily in our determinations on reasonable progress. (See our discussion in the response to Comment 12B on how visibility was weighed for the BART determinations.)

In 40 CFR 51.308(d) it states "The reasonable progress goals must provide for an improvement in visibility for the most impaired days over the period of the implementation plan and ensure no degradation in visibility for the least impaired days over the same period." 40 CFR 51.301 states "most impaired days means the average visibility impairment (measured in deciviews) for the twenty percent of monitored days in a calendar year with the highest amount of visibility impairment." Least impaired days means the average visibility impairment (measured in deciviews) for the twenty percent of monitored days in a calendar year with the lowest amount of visibility impairment. Because of the reasonable progress requirements and the regulatory definitions, we believe 98th percentile values for visibility improvement are inappropriate.

The maximum amount of improvement that would be achieved by the top controls listed in Table 9.9 is:

Source	TRNP*	LWA*
AVS (each unit)	0.028%	0.051%
Coyote Station	0.112%	0.205%
Tioga Gas Plant	0%	0.255%

* Calculated from the baseline visibility conditions.

If the top technologies from Table 9.9 are assessed cumulatively, the improvement would be 0.169% at TRNP and 0.561% at LWA. The Department considered this amount of improvement to be inconsequential. The other technologies evaluated would provide even less improvement. The capital cost to provide this much improvement is estimated at 243 million dollars with an annualized cost of over 68 million dollars. The cost effectiveness is over 618 million dollars per deciview at LWA and 2.3 billion dollars per deciview at TRNP. EPA's Guidance for Setting Reasonable Progress Goals Under the Regional Haze Program (June 1, 2007) states "Therefore, in assessing additional emissions reduction strategies for source categories or individual, large scale sources, a simple cost effectiveness estimates based on a dollar-per-ton calculation may not be as meaningful as a dollar-per-deciview calculation... ." It appears EPA is ignoring its own guidance by dwelling on the dollar-per-ton cost effectiveness and ignoring the dollar-per-deciview cost effectiveness. We stand by our decision not to require additional controls.

Comment 14: Section 9.5.1, Time Necessary for Compliance, p. 185: As noted in our August 12, 2009 preliminary comments on the WRAP's May 18, 2009 Draft *Supplementary Information for Four-Factor Analyses for Selected Individual Facilities in North Dakota*, this timeline for compliance seems to be overestimated and/or doesn't account for steps that can be completed in parallel. In addition, the time necessary for compliance should not include time to develop regulations. If new regulations are necessary, such regulations need to be submitted with the forthcoming SIP. The WRAP report indicated that two years may be needed to develop the rules to implement Reasonable Progress strategies. This statement implies that the State lacks authority to develop and submit a SIP to address Reasonable Progress and Long-Term Strategy requirements, including relevant Reasonable Progress measures. Please verify that these concerns with the WRAP report were not carried over into the North Dakota SIP.

Response: The Department has stated that up to 6½ years would be needed to implement any additional controls. In the case of the Coyote Station it may be longer depending on when that portion of the SIP is approved. The Department believes it can issue Permits to Construct for the Coyote Station and Heskett Station that contain requirements to reduce emissions. However, we believe the full-time frame listed in the EC/R report is reasonable.

Comment 15: Section 9.5.1, Reasonable Progress Goals – Required Controls for Point Sources, p. 186-187: Again for comparison, since NDDH has chosen to rely on visibility improvement in determining Reasonable Progress controls, it is appropriate to also provide and consider the 98th percentile day results in aggregate. In addition, given that the cost effectiveness ($/ton) for reducing emissions at a number of the sources considered for Reasonable Progress controls is similar to, or less than, the cost effectiveness that NDDH considered appropriate for control at the BART sources, it is unclear why some additional Reasonable Progress controls are not warranted in the current planning period.

Response: See responses to Comments 12B and 13.

Comment 16: Section 9.5.4, Coyote Station, p. 189: It appears that NDDH believes at least this minimal level of control is reasonable now. As such, why isn't it included as a required Reasonable Progress control in the SIP? Further, why is the related Permit to Construct contained in Appendix A, BART Modeling Protocols and Analyses? Finally, this "agreement" must not preclude NDDH's re-evaluation of this source in future planning periods.

Response: The Department determined under the Reasonable Progress Analysis that no additional controls were required at the Coyote Station. Although no additional controls are required by rule or law, we have reached an agreement with the owners of the plant to reduce NO_x emissions even though no visibility improvement will be realized. To avoid any precedent for other sources under the Reasonable Progress analysis, the Coyote discussion is not included under the Point Sources Section (Section 9.5.1). The discussion regarding the Coyote Station has been relocated to Section 10.6.1, Emissions Reductions Due to Ongoing Air Pollution Control Programs.

Comment 17: Section 9.6, Visibility Modeling and Weight of Evidence, p. 191-193: The statement that implementing additional controls at Antelope Valley Station, Coyote Station, and Tioga Gas Plant "will not significantly affect current visibility conditions or the amount of time necessary to achieve natural conditions" – is misleading. Visibility improvement in aggregate should result in more progress. These sources are within NDDH's control (as opposed to the Canadian sources) and are cost effective to control. We understand that NDDH is not able to meet the uniform rate of progress in this planning period, but this does not justify the lack of Reasonable Progress controls on these sources.

Response: We strongly disagree with your assertion that the statement that additional controls at the Antelope Valley, Coyote Station and Tioga Gas Plant "will not significantly affect current conditions or the amount of time necessary to achieve natural conditions" – is misleading. As pointed out in the response to Comment 13, application of the most efficient cost effective ($/ton) controls will only produce a 0.169% improvement in visibility during the most impaired days at TRNP and 0.561% at LWA. The amount of time to achieve natural conditions would decrease from 156 years to 151 years at TRNP and from 232 years to 201 years at LWA. We stand by our statement.

As for requiring controls, see the Response to Comments 12B and 13 and our Reasonable Progress analysis with the SIP.

Comment 18: Table 9.14, Reasonable Progress Goals, p. 195: The addition of the goals based on WRAP's modeling approach is useful; however, clarification should be provided as to which goals are being established by NDDH.

Response: The SIP has been revised to indicate the Reasonable Progress goals are based on the Department's modeling.

Comment 19: Section 10.6.5, Smoke Management Techniques for Agriculture and Forest Management, pp. 204-205: A statement needs to be added that NDDH will re-evaluate potential emissions reductions on sources within North Dakota's control in future planning periods.

Response: Agreed

Comment 20: Section 11.6, Rules for Non-BART Point and Area Sources, p. 213: Although NDDH has determined that it is not reasonable to control these sources during the current planning period, this section implies that NDDH lacks authority to develop and submit a SIP to address Reasonable Progress and Long-term Strategy requirements, including relevant Reasonable Progress measures. It is not appropriate to use this lack of authority as justification for elimination of Reasonable Progress controls in the current planning period nor is a commitment of this nature acceptable to address requirements.

Response: The Department has not used the lack of clarity regarding implementation of controls on non-BART sources as a reason for not requiring control. The reasons for not requiring control are based on the four statutory factors (see Section 9.5.1 of the SIP and our response to Comments 12B and 13). Since our analysis of the four statutory factors indicated additional controls were not reasonable, we had no reason to clarify our authority for these controls. Before the next review period, the NDDH's authority will be clarified.

Comment 21: Appendix A.2.2, AECOM's August 12, 2009 Response to Concerns Regarding BART Exemption Modeling for Heskett Unit 2:

(A) NDDH's 2006 CALPUFF BART exemption modeling indicated that baseline emission impacts would result in a visibility impact of 0.82 deciviews (dv) at TRNP and 0.58 at LWA. Predicted visibility impairment exceeding 0.5 dv would make the facility subject-to-BART. MDU then contracted with ENSR to make refinements to the State's analysis that included reducing the grid size from 3 km to 1 km and a number of other settings in the model that are not consistent with current EPA defaults settings for the CALFUFF model. To address this issue, in November 2009 NDDH, EPA, MDU, and the FLMS negotiated a modeling protocol that involved rerunning the model for BART applicability using the current EPA default model settings. MDU recently completed the revised modeling and provided the results in a December 17, 2009 report. The results show that the facility is exempt from the BART requirements. EPA has obtained and is reviewing the modeling files to verify these results. Given that this updated modeling was completed after the start of the current public comment period on the Regional Haze SIP, EPA will provide additional comments on this issue if the revised modeling fails to address our concerns. Please note that NDDH will need to revise the SIP to include the revised modeling and your related conclusions. The revision will need to follow North Dakota's public participation process for SIP revisions.

(B) We also note an inaccurate reference in Appendix A.2.2 stating that EPA accepted Rapid Update Cycle (RUC) prognostic meteorological data for use in NDDH's SO_2 Periodic Increment Review. EPA has not taken action to approve NDDH's Periodic Increment Review.

Response:

(A) The Department believes MDU Heskett Unit 2 is exempt from the BART requirements and apparently EPA now agrees with that determination. The source will be reviewed under the Reasonable Progress requirements. An initial review of this source indicates a 95% reduction in SO_2 (wet scrubber) and a 40% reduction in NO_x (SNCR) will produce a visibility improvement of only 0.009 deciviews at TRNP and 0.003 deciviews at LWA during the most impaired days. It is unlikely that any additional controls will be required.

(B) We acknowledge that final action has not been taken.

Comment 22: Appendix B.5, BART SCR Technical Feasibility Analysis for North Dakota Lignite:

(A) While we agree with your determination that Low Dust SCR and Tail-End SCR are technically feasible, we do not agree with all of the technical aspects or conclusions of the analysis, especially as they relate to High Dust SCR. As you know, we have done a thorough review of the technical feasibility analyses submitted by Minnkota for Units 1 and 2 at Milton R. Young Station and NDDH's preliminary BACT determination published for public notice on June 11, 2008. Our comments and supplemental information were provided in previous letters from EPA Region 8's Office of Enforcement, Compliance, and Environmental Justice, to the North Dakota Department of Health, Division of Air Quality. Our letters provided substantial information and evidence that all SCR technology, including High Dust SCR, is technically feasible at facilities burning North Dakota lignite, and we continue to stand by those comments.

(B) Please see p. 8 of the Institute of Clean Air Companies (ICAC) May 2009 White Paper on SCR Control of NO_x Emissions from Fossil Fuel-Fired Electric Power Plants, contained in Enclosure 3 for your use. This paper addresses feasibility of SCR on lignite-fired boilers and, while noting "[l]ignite from different mines has some common characteristics but also differs in some significant ways," states that "[w]ith proper design, lignite applications can be successful." The ICAC paper addresses the technical issue of high sodium in lignite and states that "[t]hese poisons are not an issue as long as the catalyst stays above dew point conditions."

<u>Response</u>:

(A) We stand by our response that HDSCR is not technically feasible for North Dakota lignite. The preponderance of the evidence indicates HDSCR cannot be successfully operated on North Dakota lignite and is, therefore, not technically feasible.

(B) This White Paper was developed by companies that are in the business of selling air pollution control technology. Therefore, their statements must be evaluated carefully and proper consideration given to the source. The White Paper states "These poisons [Na/K] are not an issue as long as the catalyst stays above dew point conditions." This is in direct contrast to Zheng, et. al., (2008) that found that the submicron Na and K aerosols migrate into the catalyst pores by diffusion, most likely surface diffusion, with temperatures above the dew point. Zheng, et. al., found rapid catalyst deactivation under normal operation conditions. This statement is also in conflict to experience with biomass boilers. Under normal operating conditions (i.e. above the dew point) rapid catalyst deactivation has been found. Most, if not all, biomass boilers are now equipped with tail-end SCR (e.g. Amager Station). Ceram, in Minnkota's response to questions about the SCR cost estimate (2/11/10), states "Small aerosol particles can penetrate and neutralize active catalyst sites even in dry conditions." Ceram also stated "Catalyst installed in even low dust and tail-end locations are poisoned from the exposure to the flue gas" and "moreover, the high levels of phosphorus, sodium and potassium found in the mineral analysis will increase deactivation rates." It is also in direct conflict with the Minnkota efforts to secure a catalyst guarantee for a tail-end or low-dust SCR. Two companies, Ceram and Haldor Topsoe, refused to offer guarantees without previous pilot-scale testing.

The White Paper does not state which type of SCR (HDSCR, LDSCR, or TESCR) will be successful with proper design. The Department has determined that only LDSCR and TESCR will be successful. The Department's opinion may not be in conflict with the White Paper; the White Paper is just not specific enough for any determination to be made.

Comment 23: Appendix C.1, Leland Olds SCR Cost Estimate: We have numerous concerns with the May 2009 Leland Olds BART Update, Tail-End Selective Catalytic Reduction (TESCR) Cost Effectiveness Evaluation, as prepared by Sargent & Lundy for Basin Electric and utilized by NDDH in its BART determinations for Leland Olds. In summary, several unsubstantiated and likely inappropriate assumptions impact the cost effectiveness numbers relied upon by NDDH to eliminate SCR in its BART determinations for Leland Olds Units 1 & 2. These assumptions result in calculated costs for TESCR that are biased high. If a more reasonable set of assumptions are incorporated into this analysis, it will likely show SCR to be cost effective on the cyclone unit (Leland Olds Unit 2), and it may also be cost effective for the wall-fired unit (Leland Olds Unit 1). Please see our detailed comments in Enclosure 2.

Response: For making cost estimates for control technology review, the BART Guideline recommends the EPA Air Pollution Control Cost Manual (EPA/452/13-02-001). However, the manual cannot be used for determining the cost of TESCR (Section 2.4 for Selective Catalytic Reduction). Although the Control Cost Manual cannot be used for TESCR, it does provide a statement on the accuracy of the cost estimates generated by the manual. Chapter 2, Section 2.2 states "As mentioned in Chapter 1.1, the costs and estimating methodology in this Manual are directed toward the "Study" estimate with a nominal accuracy of ±30% percent." We believe Basin Electric's estimate is within ±30%. With the respect to the specific comments:

(A) Steam for reheat.

Basin Electric has indicated that using steam for reheat in North Dakota winters represents unique challenges that would greatly increase operation and maintenance costs and downtime. A steam reheat system would have to be designed for -40°F temperatures plus the operator must have the capability to service the system in the harsh conditions of a North Dakota winter. As indicated by Minnkota, their previous experience with the reheat of the flue gas from Unit 2 using steam was not positive and was abandoned. The Department believes this experience is directly applicable to Leland Olds Station.

There is no indication that the units at Leland Olds are turbine limited. Therefore, using steam could have an electrical penalty for the units. For Unit 2, this could amount to nearly 5 million dollars per year.

(B) Engineering calculations should be able to provide a reasonable estimation of the cost within an accuracy of +/-5%.

This statement is contrary to the BART Guideline which recommends using the Control Cost Manual which has an accuracy of ±30%. Perry's Chemical Engineer's Handbook describes five levels of cost estimates 1) Order of Magnitude, 2) Study with an accuracy of ±30%, 3) Preliminary with an accuracy of ±20%, 4) Definitive with an accuracy of ±10%, and 5) Detailed with an accuracy of ±5%. Detailed cost estimates require final drawings, specifications and site surveys. In order to achieve a ±5% accuracy, detailed engineering analyses including plans and specifications for the SCR system will have to be prepared. The BART Guideline does not require this level of detail.

(C) The operating life of TESCR catalyst can be expected to be in the range of 50,000 hours.

Minnkota was unable to secure any guarantee for the life of a TESCR catalyst. EPA's expected catalyst life appears inconsistent with at least two catalyst/SCR vendors. Without pilot scale testing, no definitive statement regarding catalyst life can be made.

(D) Only when the catalyst in the TESCR is being cooled down to below the water dew point, such poisoning will occur.

See response to Comment 22. In Haldor Topsoe's paper entitled "The Influence of Biomass Burning in the Design of an SCR Installation" they indicate that the tail-end installation after a wet FGD will only <u>minimize</u> the amount of poisoning species entering the SCR. To counter this poisoning, Haldor Topsoe used four counter measures to <u>minimize</u> risk. These included a "bio-optimized" catalyst with a high vanadium content and a high number of active sites to make the catalyst less susceptible to poisoning by alkali metals. All of this indicates that poisoning of TESCR catalyst is a real concern especially with organically associated sodium and potassium.

EPA claims that the wet scrubber will mostly absorb the sodium and potassium aerosols in the acidic scrubber slurry. This statement is in conflict with data from Markowski et. al. (1983). Markowski's data indicates the wet scrubber at M.R. Young Unit 2 does not remove the submicron sodium and potassium aerosols that cause SCR catalyst deactivation. The data actually suggests an increase in submicron aerosols. Based on this data, the Department believes a wet scrubber that is designed for sulfur dioxide control will have little effect on the sodium and potassium submicron aerosols. However, the Department agrees that the sodium and potassium aerosol concentration entering either a LDSCR or TESCR will be sufficiently low to allow successful operation.

(E) The Leland Olds LDSCR and TESCR systems would be similar to the M.R. Young systems. Minnkota, in their detailed response to questions by the NDDH and EPA (2/11/10), has responded to this same issue. The SCR process consultant for Minnkota calculated a temperature gradient of 43-45°F. The catalyst vendor recommended a design up to 600°F. Based on 50°F temperature gradient and a heat input of 5120 x 10^6 Btu/hr for Unit 2, Basin Electric has estimated that reheating the flue gas will consume approximately 115 x 10^6 Btu/hr. Minnkota has estimated, based on a temperature gradient of 43°F and a heat input of 4885 x 10^6 Btu/hr, that 96.2 x 10^6 Btu/hr will be required to reheat the flue gas for Unit 2. The difference is attributable to the 7°F temperature gradient difference and the difference in heat input to each unit. Since final design specifications are not required for this estimate ($\underline{+}$30% accuracy required), Basin Electric's estimate of a 50°F temperature gradient and a flue gas temperature of 600°F are reasonable.

EPA claims that the only relevant information from pilot testing would be the catalyst deactivation rate. The Department believes pilot scale testing will also help optimize the catalyst volume that is required; the catalyst surface area required, the required reagent injection rate, expected reagent slip, whether a wet ESP is required for ammonium bisulfate and/or ammonium sulfate emissions and an appropriate catalyst maintenance plan. All of these issues will affect the annualized cost. However, the NDDH believes the cost of LDSCR and TESCR can be estimated, without pilot testing, to within ±30 which is equivalent to the accuracy of EPA's Control Equipment Cost Manual which is recommended by the BART Guideline.

EPA has indicated that two weeks is too much time to replace the catalyst. EPA has suggested that five days would be more appropriate. Assuming 3 layers of catalyst, each layer would contain 177 m^3 of catalyst or approximately 85 modules. Schirmer et. al. in the paper In-Situ SCR Catalyst Replacement indicated it took 9 days to replace 90 modules at the TVA Allen Fossil Plant not including cool down and vacuuming of the reactor. Cool down of the reactor and vacuuming is expected to take 3-4 days. In addition, reheating of the SCR prior to startup will take another 1-2 days. Based on this data, the NDDH believes the S&L estimate of two weeks to replace the catalyst is reasonable.

EPA has questioned the catalyst replacement schedule. Basin Electric has estimated the cost based on a six-month and 12-month replacement schedule. The NDDH believes LDSCR and TESCR will have a replacement schedule that is probably greater than 12 months (10,000 hours equals 13.7 months). Although 12 months is slightly less than the 10,000 hours the Department suggested was necessary for technical feasibility, no one knows the actual deactivation rate without pilot scale testing. Because of the lack of vendor guarantees, a replacement schedule of 12 months appears reasonable. A replacement schedule of 13.7 months would decrease the cost effectiveness by approximately $52 per ton or 1.0 – 1.4%. The Department considers this insignificant. The Department has determined that the cost is excessive at both the low end and high end. The Department also considered the amount of visibility improvement in the BART determination. The amount of improvement between SCR and the next most efficient option is negligible.

Specific issues include:

(A) The catalyst volume of 530 m^3 seems high.

> Minnkota has projected a total initial catalyst volume of 768 m^3 for M.R. Young Unit 2 (256 m^3 per layer and 3 layers). M.R. Young Unit 2 is rated at 477 MWe and Leland Olds 2 is rated at 440 MWe. The M.R. Young Unit 2 design volume was provided by a vendor. The DOI, in their consultation comments, estimated that 645 m^3 of catalyst would be required for Leland Olds Unit 2 based on the EPA's Air Pollution Control Cost Manual. Given the Minnkota catalyst volume estimate, the DOI estimate and the uncertainties regarding the catalyst deactivation rate, the catalyst volume appears to be on the low side and therefore acceptable for the cost estimate.

(B) The selected NO_x Efficiency of 85% appears low – see response to Comment 25.

(C) A capacity factor of 92.3% is erroneous since it is based on catalyst replacement every six months.

From 2000-2008 Leland Olds Unit 2 had a capacity factor of 87.4% based on hours of operation. Catalyst maintenance will decrease this availability. Using a capacity factor of greater than 92.3% does not appear to be reasonable based on the operating history.

(D) The price of $7,500 per cubic meter appears high.

This is the same cost provided for the M.R. Young Station which the NDDH understands is based on a vendor quote plus shipping, handling and taxes. It appears the cost is reasonable.

(E) The power cost of five cents per kilowatt appears high.

The Energy Information Administration (EIA) reports that the average retail price of electricity in North Dakota is 6.89 center per kilowatt. They also report that the average wholesale price of electricity in the MRO (formerly MAPP) area was 4.86 cents per kilowatt hour which is the lowest in the country (5.72 cents/kilowatt hour average for the U.S.). The S&L estimate of five cents per kilowatt hour appears reasonable.

(F) Natural gas prices are currently between $3 to $5 MMBtu rather than $8 to $12 MMBtu (inferred that cost of natural gas is too high).

Wellhead natural gas prices have been as much as $14/MMBtu in the recent past. Projecting natural gas prices must take into account the U.S. economy, new legislation or rules for the control of greenhouse gases including the surge in demand for natural gas as a substitute for other fossil fuels to reduce GHG, market price speculation, the ability of supply to keep up with demand and inflationary pressures. The Energy Information Administration (EIA) has predicted that the commercial price will range from $10.65 - $12.12 per MMBtu from 2011-2030 (calculated as 2008 dollars). The NDDH believes $8 - $12/MMBtu is a reasonable estimate of average natural gas prices over the life of the SCR system given the many factors that can influence the cost.

(G) Ammonia costs are currently more in the range of $300-400 per ton rather than $450-700 per ton.

Ammonia costs are directly related to the cost of natural gas since most anhydrous ammonia is produced from natural gas. Based on the NDDH's expectation that natural gas prices will increase, the range of ammonia cost of $450 - $700 per ton is reasonable.

(H) EPA notes that SCR retrofits in the U.S. are well below the $/kw price range calculated by S&L.

EPA provided no details to support this claim. The NDDH notes that Basin Electric's estimate is for TESCR; most SCR installations in the U.S. are HDSCR which have a much lower cost. ERG has noted in their review of the PGE Boardman BART analysis that the cost of SCR has escalated rapidly since 2004. ERG found actual costs exceeding $267/kw for HDSCR (2007 dollars). For the Boardman Plant, ERG's estimate was $206 - $267/kw. The Black and Veatch estimate was $309/kw. S&L has used $376-$387/kw for TESCR which includes a reheat system and gas-to-gas heat exchangers not associated with HDSCR. The NDDH believes the capital cost estimate is reasonable given the uncertainties such as the design volume of the reactor.

Comment 24: Appendix C.4, November 2009 Minnkota Supplemental NO_x BACT Analysis Reports for Units 1 & 2: In response to Minnkota's Supplemental BACT Reports, NDDH sent a November 25, 2009, letter to Minnkota citing a lack of detailed and comprehensive cost data documentation in the Supplemental BACT Reports and the failure to address the use of main boiler steam for flue gas reheat. NDDH requested that this information be submitted, as well as a demonstration that the cost of NO_x removal for SCR is disproportionately high compared to the cost of NO_x control in other recent Best Available Control Technology (BACT) determinations for coal-fired power plants. EPA has reviewed the Supplemental BACT Reports and wholly supports the statements in NDDH's November 25, 2009 letter. Given the fact that you are not satisfied with Minnkota's analysis and have requested additional supplemental information, it is not appropriate to rely on this cost analysis in the BART context at this time. EPA has also identified additional problems and concerns with the Supplemental BACT Reports which must be addressed for BART purposes as well, in accordance with the requirements of 40 CFR 51.308(e)(1). (SIP must include documentation for BART analyses.) These additional problems and concerns are summarized as follows:

(A) The <u>additional</u> outage time estimated in the Supplemental BACT Reports for catalyst cleaning/replacement seems very high and is not supported. Considering there are regular planned outages for both units, these times should be attributed to catalyst cleaning/ replacement activities that would not otherwise be accommodated during these planned outage events.

(B) The estimated catalyst replacement schedule under both scenarios used in the Supplemental BACT Reports is much shorter than EPA would expect for Low-Dust Selective Catalytic Reduction (LDSCR) and TESCR systems. Furthermore, the assumption that one layer of catalyst would be replaced during each planned boiler cleaning outage is made without any justification and should therefore be given little to no credibility in the final conclusions of the BACT analysis.

(C) All vendor correspondence related to catalyst costs and replacement, as described in the Supplemental BACT Reports, must be provided. This includes the original requests submitted to the vendors by Minnkota and/or their consultants.

(D) While the Supplemental BACT Reports give a general description of how the pressure drops and parasitic loads were calculated, Minnkota or NDDH must provide more details, including calculations to justify these high values.

(E) No data is provided for the temperature gradient of the regenerative gas-to-gas heat exchanger, which is essential to determine the required reheat input for either a natural gas-fired or steam system. Furthermore, the assumed value of flue gas reheat of 600 º F must be justified. We would also expect this temperature to be different for a LDSCR and TESCR due to significantly different SO_2 and SO_3 concentrations.

(F) The Supplemental BACT Reports claim there were no similar projects "on coal-fired power plants in the United States that could be used, with adjustments, to properly represent total installed cost" for MRYS. Minnkota or NDDH should consider the data from the PSE&G Mercer and We Energies South Oak Creek facilities that have installed, or will be installing, LDSCR systems.

(G) The cost values used for catalyst, natural gas, and electricity appear higher than current prices and must be substantiated. Furthermore, the Supplemental BACT Reports assume urea would be used as opposed to anhydrous ammonia. Both options should be evaluated and the least costly option selected, unless there is a compelling reason to use the more expensive option.

Response: Minnkota has addressed the use of steam for reheat in their December 11, 2009 response to NDDH questions. The NDDH asked for additional support for Minnkota's position on steam for reheat and several other items. Minnkota has supplied a response to all of the questions the NDDH and EPA posed regarding the cost estimate (2/11/10). The NDDH has reviewed Minnkota's responses and finds them to be acceptable. The NDDH is confident that the range of costs provided by Minnkota have an accuracy of ±30%, which is the accuracy of EPA's Air Pollution Control Cost Manual that is recommended by the BART Guideline.

In determining BART for NO_x at M.R. Young Station, the NDDH considered all five statutory factors. Our analysis of the costs indicate that both costs calculated by the NDDH and by Minnkota are excessive over the entire range of the costs estimated. In addition, the incremental cost effectiveness of SCR (LDSCR and TESCR) + ASOFA is excessive when compared to SNCR + ASOFA. Finally, the incremental amount of visibility improvement of SCR + ASOFA versus SNCR + ASOFA is negligible. Each of these factors (i.e. cost effectiveness, incremental cost or visibility improvement) by themselves would dictate that SCR + ASOFA is not BART.

The NDDH also considered the uncertainties regarding the technical feasibility of LDSCR and TESCR. Since Minnkota was unable to secure a vendor guarantee, the successful application of LDSCR and TESCR is more questionable.

Having considered the cost effectiveness, incremental cost, the incremental visibility improvement, and the uncertainties regarding the successful application of SCR to a source combusting ND lignite, the NDDH has determined that BART is not represented by SCR.

Comment 25: Appendix J.1, Consultation with Federal Land Managers: We note that in several of your responses to FLM comments, you cite to EPA's August 28, 2009 Advanced Notice of Proposed Rulemaking (ANPR) regarding the Four Corners Power Plant BART analysis. The ANPR does not represent an Agency decision but rather includes information on which EPA

Region 9 seeks comment. At this point, no Agency position has even been proposed, much less finalized. It is not appropriate to rely on the August 28, 2009 ANPR to support your position regarding BART analyses in North Dakota.

<u>Response</u>: The Department has reviewed the EPA Air Pollution Control Cost Manual which states "In practice, SCR systems operate at efficiencies in the range of 70% to 90%." EPA's Air Pollution Control Technology Fact sheet for selective catalytic reduction (EPA-452F-03-032) states "SCR is capable of NO_x reduction efficiencies in the range of 70% to 90%." The Oregon DEQ hired Eastern Research Group, Inc. (ERG) to review the BART analysis for the PGE Boardman Plant. In their review, ERG stated "With regard to the performance of existing low NO_x burners (LNB) with overfire air (OFA) and SCR, reductions of 70 to more than 90 percent have been documented from recent installations; however, these are based on units that operate mainly during the ozone season and that have substantial opportunity for off-season maintenance and catalyst cleaning. The impact of existing LNB with OFA and SCR of the Boardman Plant under year-round operation would need to be considered in selecting a permit level." The NDDH believes the use of 80% is a reasonable choice for a source that must meet a BART emission limit on a long-term continuous basis.

In addition to the ANPR estimate for SCR at the Four Corners Power Plant, the Department also reviewed the analysis commissioned by the Oregon DEQ for the cost of SCR at the PGE Boardman Plant. The analysis, which was prepared by Eastern Research Group, Inc. (ERG) states, "Nonetheless, all of these sources do point to a rapid escalation in SCR installed costs since 2004. ERG analyzed the 2007 cost-basis data by eliminating the three highest and one project that was known to be very dissimilar to the Boardman Plant characteristics. The remaining nine projects range from $207/kw to $267/kw, with an average of $227/kw. ERG believes that this is a reasonable representation of 2007 costs of large SCR installations under normal retrofit conditions." This cost is two to three times the amount that would be estimated using EPA's Control Cost Manual. Further, these costs are for HDSCR. The cost for LDSCR and TESCR will be substantially higher because of the capital cost for the reheat system (including heat exchangers) and the operating cost for reheating the flue gas.

<u>Comment 26</u>: SO_2 and NO_x analyses: In general, analyses of control options and proposed limits should not be based on worst-case coal scenarios and/or highest calendar year emission rates. Use of averages should allow for accommodation of worst-case situations and will ensure that the more common conditions are adequately limited.

<u>Response</u>: The BART guidelines states "the baseline emissions rate should represent a realistic depiction of anticipated annual emissions for the source." Using worst-case emissions represents a realistic scenario because the scrubber will have to be designed for that coal and operation and maintenance costs will be higher with this higher sulfur coal. North Dakota lignite is extremely variable in both quality and sulfur content. Using an average sulfur content will not accommodate worst-case conditions. For Minnkota, one standard deviation of the sulfur content amounts to 0.53% sulfur or 57% of the average sulfur content. Prediction of future sulfur content has been based on a limited number of core samples. Using an annual average for the baseline eliminates some of this variability; however, it does not eliminate it all. The Department believes that a sulfur content at, or near, the maximum annual average provides a realistic depiction of emissions. This is the same as using the maximum two years of the last five or ten years to predict the baseline emission rate as suggested by EPA in the BART Guideline and in response to questions on BART (Question 7, August 3, 2006). The difference is that you have to look into the future to see what two years will provide the maximum emission rate.

For BART, EPA has indicated the limit must be on a 30-day rolling average. A 30-day rolling average emission rate is not equivalent to an annual average emission for North Dakota lignite which is highly variable. Our review of scrubber systems in North Dakota indicates as much as a one-third difference between these two emission rates. To account for this variability, the annual emission rate must be adjusted upward to get a 30-day rolling average. In addition, the Department has not allowed an exemption from the BART emission limits during startup/shutdown or malfunction (SSM). Therefore, SSM must be considered in setting the BART emission limit. Using a near maximum sulfur content allows the Department to set the BART limit without making an adjustment for SSM.

For NO_x, the average of the highest two years out of the last five years was used by the Department to establish a baseline. This is consistent with the BART Guideline (Section IV.D.4.d.1). It is also consistent with EPA's August 3, 2006, response to comments (Question 7) and consistent with BACT determinations.

Again, a 30-day rolling average NO_x emission rate is not equivalent to the annual average emission rate for boilers firing North Dakota lignite. Our analysis indicates the 30-day rolling average can be 15% or more higher than the annual average emission rate especially when SSM is considered.

Comment 27: NO_x analyses, Step 3: Evaluate Control Effectiveness of Remaining Control Technologies: Based on our comments #22-24 above and Enclosure 2, please ensure that inappropriate assumptions in the cost analyses for SCR were not carried over to the NDDH BART determinations for any of the facilities reviewed. In addition and as we have commented in previous correspondence, incremental cost analyses are intended to be a useful supplement, not a replacement, for standard $/ton calculations. It is not unusual that the incremental costs will be greater than the average cost effectiveness as the level of control increases, but this should not be an automatic basis for eliminating an option which has a reasonable average cost effectiveness.

Response: The Department believes that cost estimates are with ± 30% of the actual cost which is similar to the costs provided by EPA's Control Cost Manual (see Responses to Comments 22-24).

Incremental cost was considered in evaluating the various control options. As provided in the BART Guideline, "The greater the number of possible control options that exist, the more weight should be given to the incremental costs vs. average costs." The Department evaluated at least five different NO_x control options for each source subject to BART. As such, more weight was given to the incremental cost as recommended by the BART Guideline. The Department considered all five statutory factors in determining BART including average cost effectiveness and incremental cost.

<u>Comment 28</u>: The visibility impact analyses need to eliminate the reference to "3 units" for TRNP, as requested by the FLMs. We note that this change was made in the SIP text and should be carried over to these documents. TRNP was identified as a single national park under the Clean Air Act Amendments of 1977 (42 U.S.C. 7472); thus, there is only one mandatory Class I Federal area for this park. By dividing this Class I area into 3 units, there may be slight reductions in benefits predicted when modeling the visibility effects of applying controls.

***<u>Response</u>*:** North Dakota has two Class I areas within its boundaries: the Theodore Roosevelt National Park which consists of three separate and distinct units and the Lostwood National Wildlife Refuge Wilderness Area. The Department considers the three units of Theodore Roosevelt National Park to be three separate areas for modeling purposes for the following reasons:

A. Theodore Roosevelt National Park (TRNP) as a PSD Class I area consists of three units (see 44 FR (November 30, 1979) at 69125 and 69127, 40 CFR § 81.423 and NDAC § 33-15-15-01.2 (Scope) relating to 40 CFR 52.21(e)). The areas are not contiguous. The North Unit and South Unit are separated by approximately 38 miles.

B. Federal regulation, 40 CFR 51.301, states "*Adverse impact on visibility* **means, for purposes of section 307, visibility impairment which interferes with the management, protection, preservation, or enjoyment of the visitor's visual experience of the Federal Class I area. This determination must be made on a case-by-case basis taking into account the geographic extent,** intensity, duration, frequency and time of visibility impairments and how these factors correlate with (1) times of visitor use of the Federal Class I areas, and (2) the frequency and timing of natural conditions that reduce visibility. This term does not include effects on integral vistas." (Emphasis added) Combining the three units of TRNP into a single area for visibility analysis fails to address the "geographic extent" of any visibility impairment.

C. The North Unit is not visible from the South Unit and vice versa. The commingling of receptors from the units for a visibility analysis misrepresents the ability of a park visitor to observe features in another unit.

   Any viewable scenes outside any unit of TRNP from within the unit are "integral vistas". The effects on integral vistas are not considered when determining whether an adverse impact on visibility will occur. There are no geological features, terrain or structures in any unit of TRNP that are viewable from another unit across the land regions separating the units. For example, terrain peaks in the South Unit would have to rise at least 900 feet above terrain in the North Unit, due to the Earth's curvature, to be seen by a visitor in the North Unit. So the visual range of visitors in one unit does not include aspects of another unit.

D. The Department has treated the units as separate Class I areas for 30+ years for purposes of PSD increment consumption without objection from EPA or the FLMs prior to 2006.

E. Treating the three units as a single Class I area effectively extends Class I status to areas between the units which are classified as Class II by rule and law.

F. The units have three different names, the South Unit, the North Unit and the Elkhorn Ranch Unit.

Comment 29: Section II.A.2., Compliance Date: The last phrase "…approves this permit as part of the BART SIP" needs to be revised to "…approves this permit as part of the Regional Haze SIP."

Response: Agreed

Comment 30: Unit 1 SO_2 BART evaluation, p. 5: As we have commented in previous correspondence, we have concerns with the use of 35(s) as an alternative emission factor for SO_2. NDDH's response did not adequately justify the use of the alternative. The alternative factor was based on a study contained in NDDH's periodic review of PSD SO_2 increment consumption. In that study, an emission factor of 37.4(s) was proposed. For the Leland Olds BART determination, an emission factor of 35(s) was used to provide a conservative estimate of the uncontrolled emission rate. In the periodic review, NDDH apparently used CEM data from recent years to derive an alternative emission factor to estimate sulfur emissions. The EPA AP-42 emission factors were developed in the mid-1970s and include test data gathered at lignite burning power plants in North Dakota and elsewhere. EPA has concerns about using recent CEM data to adjust emission factors given that coal quality may have changed over the years, or may change in the future. However, in this instance it does not appear that the use of this alternative emission factor affects the results of the SO_2 BART determination.

Response: AP-42 makes several statements about the use of the emissions factors in the document. These include:

- Data from source-specific emission tests or continuous emission monitors are usually preferred for estimating a source's emissions because those data provide the best representation of the tested source's emissions.

- Use of these factors as source-specific permit limits and/or as emission regulation compliance determinations is not recommended by EPA. Because emission factors essentially represent an average of a range of emission rates, approximately half of the subject sources will have emission rates greater than the emission factor and the other half will have emission rates less than the factor. As such, a permit limit using an AP-42 emission factor would result in half of the sources being in noncompliance.

- Average emissions differ significantly from source to source and, therefore, emission factors frequently may not provide adequate estimates of the average emissions for a specific source. The extent of between-source variability that exists, even among similar individual sources, can be large depending on process, control system, and pollutant.

AP-42, in the Introduction-Figure 1, indicates that CEM data provides the best reliability for estimating emissions.

Based on the above, the Department believes an emission factor based on actual CEM data is far superior to the AP-42 emission factors. The baseline emissions that were estimated based on an emission factor derived from CEM data provides the most accurate data available. Using an inferior AP-42 emission factor would degrade the BART process. No changes were made based on this comment.

Comment 31: Units 1 and 2 NO_x BART evaluations:

(A) NDDH has revised its analysis and determines that LDSCR and TESCR are technically feasible and includes separate cost estimates for both systems. However, there is no explanation as to how the LDSCR cost values were obtained. Please clarify and include all supporting documentation in the SIP. See 40 CFR 51.308(e)(1).

(B) Based on our review of Basin Electric's May 29, 2009 supplemental TESCR cost analysis and NDDH's July 2009 SCR Technical Feasibility Analysis for North Dakota Lignite, we do not agree with certain assumptions used in the TESCR cost analysis. Please see Enclosure 2 for more detail, as well as our comments #22-23 above. Step 3 of the BART determination needs to be revised to address these concerns. These revisions are likely to considerably improve the cost effectiveness of TESCR for each unit, making it a reasonable selection for BART. In addition, this version of the draft BART determination includes new cost estimates for LDSCR. As explained above, it is unclear how the cost values for LDSCR were derived.

Response:

(A) The costs for LDSCR at Leland Olds were based on the cost estimate for M.R. Young 2 Station. The cost of TESCR was reduced proportionately to arrive at a cost for LDSCR. The smallest differential was used for the public comment period. The Department has revised the estimate based on the average of the "stand-alone" costs using M.R. Young 1 data for Leland Olds 1 and M.R. Young 2 data for Leland Olds 2. The detailed calculations are included in Appendix C.1.

(B) See our response to comments 22-23, we believe the cost estimate is within ±30% as would be estimated using the Control Cost Manual.

This comment seems to ignore the other four factors that are involved in making a BART determination, especially the amount of visibility improvement. Our cumulative modeling for Unit 2 shows only a 0.01 deciview improvement, in the most impaired days for SCR & ASOFA versus RRI & SNCR. The Department has the flexibility to weigh each factor as it chooses. The Department weighed visibility improvement fairly heavily in this analysis because the costs were very high. The Department has determined that the costs are excessive and the visibility improvement is so small that selection of SCR as BART is unwarranted.

Comment 32: Unit 1 NO_x BART evaluation, Step 3, p. 13: We note your reference to EPA's August 28, 2009 Advanced Notice of Proposed Rulemaking (ANPR) regarding the Four Corners Power Plant BART analysis to support the use of an 80% control efficiency for SCR with reheat. The ANPR does not represent an Agency decision but rather includes information for which Region 9 seeks comment. At this point, nothing has even been proposed much less finalized. It is not appropriate to rely on the ANPR to support your position regarding BART analyses in North Dakota. NDDH needs to explain why the more commonly accepted figure of 90% control efficiency is not warranted. For more information, please see the proposed and final Standards for Performance for Electric Utility Steam Generating Units, Industrial-Commercial-Institutional Steam Generating Units, and Small Industrial-Commercial-Institutional Steam Generating Units (70 FR 9713, February 29, 2005 and 71 FR 9869, February 27, 2006) and the May 2009 ICAC White Paper, pp. 4 and 7 (contained in Enclosure 3 of this letter).

Response: Although the ANPR was cited, that was not the only document that was relied on. The EPA Air Pollution Control Cost Manual states, "In practice, SCR systems operate at efficiencies in the range of 70% to 90%". EPA's Air Pollution Control Technology Fact Sheet for SCR (EPA-452F-03-032) states that SCR is capable of NO_x reduction efficiencies in the range of 70% to 90%. The Arizona DEQ determined that SCR with LNB could achieve 75% reduction. The Oregon DEQ commissioned Eastern Research Group (ERG) to evaluate the BART analysis for the PGE Boardman Plant. In their Technical Memorandum #2 (copy attached), ERG states "With regard to the performance of existing low NO_x burners (LNB) with overfire air (OFA) and SCR, reductions of 70 to more than 90 percent have been documented from recent installations; however, these are based on units that operate mainly during the ozone season and that have substantial opportunity for off-season maintenance and catalyst cleaning. The impact of existing LNB with OFA and SCR at the Boardman Plant under year-round operation would need to be considered in selecting a permit level." The Department stands by its decision to use 80% efficiency for SCR alone on a retrofit.

Comment 33: Unit 2 NO_x BART evaluation, pp. 23-31:

(A) Per the BART Guidelines, EPA has found that the use of SCRs at large cyclone units burning lignite enables the units to cost-effectively meet NO_x rates of 0.10 lbs/MMBtu. A revised cost analysis, using the necessary adjustments we have described in comment #23 and Enclosure 2, will most likely show that SCR is cost effective at this large boiler.

(B) For BART determinations, visibility improvement must be based on the 98th percentile day results, not the 20% worst days. We do not agree that single source modeling under the BART Guidelines overestimates visibility improvement. See comment #4 above for more detail. NDDH did not use this approach in the visibility analysis for Unit 1 and it must not be used for Unit 2.

(C) There appears to be a typographical error at the beginning of the last paragraph on p. 30 – should be "BART" instead of "BACT?"

<u>Response</u>:

(A) EPA did not evaluate the flue gas characteristics of North Dakota lignite when it established the presumptive BART NO_x levels for cyclone boilers. This is in direct opposition to the statements in the BART Guideline regarding technical feasibility of a control option (i.e. technical feasibility is based on an evaluation of the flue gas characteristics and the potential for successful application of the technology). Had EPA evaluated the flue gas characteristics of North Dakota lignite, they may have concluded that HDSCR is not technically feasible; however, no such EPA analysis is available. This failure of EPA will affect the estimated cost of achieving the presumptive levels. Had EPA conducted this analysis, the presumptive levels for cyclone boilers combusting North Dakota lignite may have been quite different.

(B) The Leland Olds Station is not subjected to the BART Guideline (i.e. <750 MWe). 40 CFR 51, Appendix Y states, "For sources other than 750 MW power plants, however, states retain the discretion to adopt approaches that differ from the guidelines". As demonstrated is the Response to Comment 4, single source modeling, as recommended in the BART Guideline, over predicts the amount of visibility improvement. The Department's cumulative modeling provides a more accurate estimate of the visibility improvement that is reasonably expected to occur and is more compliant with the requirements of Section 169A(g)(2) of the Clean Air Act than the BART single source modeling. We have exercised our discretion to use this approach for Unit 2 since the costs for SCR on a dollar per ton of NO_x removed and the incremental costs are very high.

(C) Agreed

<u>Comment 34</u>: The "References" section includes NDDH's 2005 Proposed Alternative Air Quality Modeling Protocol to examine the status of attainment of PSD Class I increments. This protocol was never approved by EPA, and contested elements of this protocol cannot be relied upon in your BART determinations.

<u>Response</u>: The reference only refers to emission factors that were calculated for the increment consumption analysis. These factors were not used in the BART analysis; a more conservative factor of 35(s) was used. As explained in the Response to Comment 30, we believe this factor provides a better estimate of sulfur dioxide emissions than the AP-42 factors because it more closely matches actual CEM data.

<u>Comment 35</u>: SO_2 evaluation, Step 2, 2nd paragraph, p. 8: There appears to be a typographical error in the 2nd to last sentence – should be Falkirk Mine instead of Center Mine?

<u>Response</u>: Agreed

<u>Comment 36</u>: SO_2 analyses, Step 5, p. 11: The reader is referred to the Great River Energy (GRE) BART Analysis, pp. 47-51, for visibility improvement analyses. While the 98th percentile results are provided in the GRE report, it is nearly impossible to understand the tables since results are combined for SO_2 and NO_x and there are no specifics provided for each scenario.

NDDH needs to extract the relevant 98th percentile results from the GRE analysis - by pollutant and by specific scenario – and incorporate them directly into the BART determination document. We note that this information has been added to the NO_x evaluation section but was still omitted from this SO_2 evaluation.

<u>Response</u>: Appendix Y to Part 51, Guidelines for BART Determinations Under the Regional Haze Rule states in part: "As long as these most stringent controls available are made federally enforceable for the purpose of implementing BART for that source, you may skip the remaining analyses in this section, including the visibility analysis in step 5. Likewise, if a source commits to a BART determination that consists of the most stringent controls available, then there is no need to complete the remaining analyses in this section." In the case of Coal Creek SO_2, the most stringent control available was selected as BART and it will be made federally enforceable in the Permit to Construct. The amount of visibility improvement can be discerned from GRE's analysis.

<u>Comment 37</u>: NO_x analyses, Step 2: Eliminate Technically Infeasible Options, p. 15: As noted above in comment #22, we have provided substantial information and evidence that all SCR technology, including High Dust SCR, is technically feasible at facilities burning North Dakota lignite, and we continue to stand by those comments.

<u>Response</u>: The Department believes the preponderance of evidence indicates that HDSCR cannot be successfully operated when North Dakota lignite is combusted making this option technically infeasible.

<u>Comment 38</u>: NO_x analyses, Step 3: Evaluate Control Effectiveness of Remaining Control Technologies, pp. 15-16: NDDH needs to explain why it accepted GRE's suggested 80% control efficiency for LDSCR instead of using the generally accepted 90% efficiency. For more information, please see the proposed and final Standards for Performance for Electric Utility Steam Generating Units, Industrial-Commercial-Institutional Steam Generating Units, and Small Industrial-Commercial-Institutional Steam Generating Units (70 FR 9713, February 29, 2005 and 71 FR 9869, February 27, 2006) and the May 2009 ICAC White Paper, pp. 4 and 7 (contained in Enclosure 3 of this letter).

<u>Response</u>: See response to Comment 32.

<u>Comment 39</u>: NO_x analyses, Step 4: Evaluate Impacts and Document Results, p. 17:

(A) The elimination of SCR and SNCR based on uncertainty surrounding "potential" ammonia contamination of fly ash is not appropriate. The BART determination should be based on the 5-factor analysis, including any necessary data to address this question. GRE claims that installation of SCR or SNCR may negatively impact fly ash sales due to ammonia slip and may result in an ash disposal problem, but does not provide any manufacturer's data, vendor information, or other technical or commercial data to support its claims. See 40 CFR 51.308(e)(1). (SIP must include documentation for BART analyses.) It is our understanding that installation of SCR and SNCR result in very little, if any, impacts to fly ash sales since the ammonia slip for each control is now very low – less than 2 ppm for SCR and less than 5-10 ppm for SNCR. Given that this concern

> wasn’t raised at the other BART sources where you have proposed SNCR, we know of no reason for it to apply to Coal Creek. We note that you cite to an example from Nebraska to support your decision. Please be advised that the cited example is from a draft BART determination analysis. The State of Nebraska has not submitted to EPA Region 7 its BART determination analysis as part of a final Regional Haze SIP. EPA Region 7 has not, and will not, make a determination regarding the approvability of Nebraska's BART determinations until it reviews all components of the final Nebraska Regional Haze SIP and acts on the revision through its own public notice and comment rulemaking.

Response: The commenter requested additional vendor information to support the determination that SCR and SNCR will result in ammonia slip and ash contamination that may reasonably be expected to negatively impact future ash sales. Additional information to support that conclusion is contained in a 2/9/10 GRE email that has been added to the supplemental information considered for the BART determination (copy attached to this response). This email contains recent testimonials from ash marketers, buyers and end product users that provide clear evidence of negative impact on ash sales and use when the ash is contaminated with ammonia by SCR and SNCR systems. The commenter statement that “It is our understanding that installation of SCR and SNCR result in very little, if any, impacts to fly ash sales”... is contradicted by these testimonials.

The commenter stated that EPA/R8 knows of no reason to apply the ash-ammonia contamination concern to Coal Creek since it was not a concern raised in NDDH BART determinations for other plants. The reason is simple: Coal Creek is the only North Dakota plant that has developed a market for ash, that has invested in the infrastructure to sell ash, and that is currently selling ash. It should be no surprise to anyone that companies do not raise the issue of lost sales for products that they do not market.

The commenter stated that NDDH could not use the Nebraska DEQ determination that SCR was not BART in part due to ash contamination by ammonia as supporting evidence because EPA has not yet approved the draft Nebraska Regional Haze SIP. It appears EPA fails to realize that evidence can be considered credible to NDDH even if EPA has not rendered an opinion on it. This evidence has weight with NDDH because the State of Nebraska has considered it and found it to be credible. Nebraska’s BART determination analysis is proof that at least one other state has come to the same conclusion on this matter as NDDH.

Comment 40: Evaluate Visibility Impacts, Step 5, pp. 17-19: We note that you have extracted the visibility impacts data from the GRE BART analysis to include in the NO_x BART evaluation. However, it appears that you have presented the combined results for SO_2 and NO_x controls, not just the NO_x results. Please clarify.

Response: See response to Comment 36.

Comment 41: Summary, p. 23: Please correct typographical errors in the SO_2 BART limits for Unit 1 and Unit 2 – should be 95% instead of 94%.

Response: Agreed

Comment 42: II.A.4.a.: Please correct the typographical error in the first paragraph – should be 95% reduction limit instead of 94%.

Response: Agreed

Comment 43: Unit 1 and Unit 2 NO_x BART evaluation:

(A) In addition to objecting to selection of SNCR as BART based on the North Dakota record, we also object to your determination that separate NO_x limits are appropriate for startup. The record does not justify the need for such separate limits, nor does it justify that the selected values represent BART. As you know, the BART Guidelines contemplate pounds per million Btu limits that apply continuously, with a 30-day rolling average period to accommodate, among other things, potential short-term fluctuations in the emissions rate that may result during startups and other conditions.

As we have noted previously, separate startup limits have not been sought by, or provided to, other facilities (Leland Olds and Stanton) for which SNCR is proposed as BART, and we know of no reason M.R. Young warrants special treatment. NDDH alludes to the Consent Decree as a basis for special treatment and a need to harmonize the "BACT limits" under the Consent Decree and the BART limits. First, the Consent Decree terms with respect to startup were the result of a negotiated compromise in the context of an enforcement action. The Consent Decree terms are not binding in the context of this BART determination, and Paragraph 66 of the Consent Decree in no way settles whether separate startup BART limits are necessary or appropriate at M.R. Young. At this time, no BACT limit has been established at M.R. Young.

NDDH also alludes to the fact that SNCR, and perhaps the overfire air system, will not work optimally during startup. Of course, this is also true for the other facilities mentioned above. This fact alone is not convincing.

NDDH then references Minnkota's claim that startup has lasted up to 61 hours for Unit 1 and that noncompliance of this length will make compliance with the 30-day rolling average emission limit "extremely difficult." From your analysis, we cannot determine whether Minnkota was exercising good air pollution control practices to minimize emissions during this period or to minimize the duration of the startup, whether this length of startup was an anomaly, or what the average emissions rate was during this period. There is no mention of startups at Unit 2 or whether the same parameters can or should be applied. Also, we cannot determine from the analysis what the expected "normal" emissions rate is using SNCR and overfire air. Presumably, your proposed BART limits already include some margin of safety for operational variation.

Also, NDDH has not evaluated potential impacts of the separate startup limits on visibility or why the separate limits represent BART. We have found no indication that the proposed startup limits represent the most stringent level of control for those periods. Furthermore, there is virtually no explanation in your BART determination for the separate startup limit for Unit 2 or why it differs so greatly from the proposed startup limit for Unit 1, or why the other terms that apply to the startup limit for Unit 2 in the permit differ from those for Unit 1 or are warranted.

Even if we found the separate startup limits to be justified, we do not believe the permit is sufficiently clear with respect to determining compliance with the normal 30-day limits and the 24-hour startup limits. In calculating 30-day averages, how will days be accounted for that include some, but not all, hours of startup? How will startups that are less than 24 hours be accounted for in calculating 24-hour averages? Finally, we question the use of heat input levels to define the end of startup as opposed to using temperatures. The latter would be more directly related to SNCR performance.

(B) As we have commented in previous correspondence, the presumptive limits should apply as the control floor since the total generating capacity is actually greater than the reported nameplate capacity of 734 MW, in fact, > 750 MW. In a November 20, 1995 letter, Minnkota advised NDDH that M.R. Young was operating at levels above nameplate and requested a change in the permit description of each unit to 277 MW for Unit 1 and 517 MW for Unit 2. These changes reflected the capabilities of the units as they "are currently with respect to generator output" and result in a total generating capacity of at least 794 MW. Per the BART Guidelines, EPA has found that the use of SCRs at cyclone units burning lignite should enable these large units to cost-effectively meet NO_x emission rates of 0.10 lbs/MMBtu.

(C) We assume that NDDH has revised its cost estimates based on Minnkota's November 2009 Supplemental NO_x BACT Analysis Reports for Units 1 & 2. Minnkota's revised cost analyses are unsubstantiated and highly questionable in many regards, as discussed in comment #24 above. Based on our review of Minnkota's supplemental reports and this BART determination, the NO_x BART determinations need to be revised to address these issues. Revisions, per our comments, are likely to considerably improve the cost effectiveness of SCR for each unit, making it a reasonable selection for BART. In addition, we have the following concerns specific to the BART determination document:

(1) NDDH has assumed a control efficiency of 90% (combined) for ASOFA with SCR. EPA expects that NO_x emissions can be reduced by 90% with SCR alone. Please see the proposed and final Standards for Performance for Electric Utility Steam Generating Units, Industrial-Commercial-Institutional Steam Generating Units, and Small Industrial-Commercial-Institutional Steam Generating Units (70 FR 9713, February 29, 2005 and 71 FR 9869, February 27, 2006) and the May 2009 ICAC White Paper, pp. 4 and 7 (contained in Enclosure 3 of this letter). Minnkota's own cost analysis uses 93.8% combined control and 90% control beyond ASOFA with SCR. The BART determination simply states that NDDH believes a reduction of 90% for ASOFA and SCR is "more appropriate on a long-term basis" without providing any rationale. Using a lower control efficiency results in significantly inflated $/ton values.

(2) The footnote on the cost tables (p. 14 and p. 29) indicates that the cost range provided is based on the difference in applying SCR to each unit as a stand alone retrofit (high end cost) and applying SCR to both Units 1 & 2 with shared facilities (low end cost). Minnkota provided these scenarios in its cost analysis. However, it appears the difference between the low and high end of the annualized cost range in NDDH's BART determination is based on "Scenarios A & B" in Minnkota's cost analysis. Scenario A (the lower cost) assumes a catalyst layer replacement (and unit outage time) every 16,000 hours, while Scenario B (the higher cost) assumes a catalyst layer replacement (and additional unit outage time) at each scheduled boiler cleaning outage. For Unit 1, this is three times a year and for Unit 2 this is four times per year. EPA believes that Scenario B is not realistic for a LDSCR or TESCR and should be completely disregarded. It appears as though NDDH is in agreement, but inadvertently used the Scenario B values for the high end of the cost range, rather than using the stand-alone values. In addition to mistakenly using the Scenario B values from Minnkota's cost analysis, it appears that NDDH used the Scenario A & B costs from the "shared facility" Table 4-7SF for Unit 1, while using the Scenario A & B costs from the "stand alone" Table 4-7SA for Unit 2. Correcting these values significantly reduces the higher annualized cost estimate (based on a stand alone unit instead of Scenario B) leading to a much smaller range between the low-end and high end estimates. The lower cost estimate (representing shared costs between Unit 1 and Unit 2 for Scenario A) and the higher cost estimate (representing Scenario A stand alone unit) should be as follows:

Unit 1 LDSCR: $31,749,000/$36,872,000
Unit 1 TESCR: $39,307,000/$44,465,000
Unit 2 LDSCR: $57,351,000/$59,881,000
Unit 2 TESCR: $66,506,000/$69,057,000

(3) Combining the higher 93.8% control efficiency for SCR + ASOFA (as submitted by Minnkota) and the worst case scenario cost described by NDDH in the BART Determination (stand alone unit costs, Scenario A), the following represents the <u>high-end</u> costs for Units 1 & 2:

Scenario A Stand Alone Costs:	Annual NOx Tons Removed	Levelized Total Cost ($1000)	Average Control Cost ($/ton)
Unit 1 (LDSCR)	9,348	36,872	3,944
Unit 1 (TESCR)	9,345	44,465	4,758
Unit 2 (LDSCR)	14,862	59,881	4,029
Unit 2 (TESCR)	14,857	69,057	4,648

On p. 17 of the BART Determination for Unit 1, NDDH “considers the cost effectiveness and incremental cost of SCR + ASOFA at the low end of the cost range to be reasonable,” while the higher end of the range was considered excessive. However, NDDH made this determination based on an error in the calculation of the high-end cost ranges (based on the Scenario B assumption that catalyst is replaced every time the unit is down for a planned outage). NDDH's low-end cost effectiveness values (\$/ton) range from \$3906/ton to \$4948/ton. Given that the corrected high-end cost estimates are not dissimilar from NDDH's reasonable low-end estimates, these high-end costs should be considered reasonable at present.

As described earlier (and apparently supported by NDDH's narrative in the BART Determination, as well as NDDH's criteria for technical feasibility, *i.e.*, a catalyst replacement schedule of 3-4 times per year would not have been considered technically feasible by NDDH), Scenario B should be dismissed. When the high-end cost range becomes the intended "Stand Alone" facility costs, and more appropriate NO_x removal efficiencies are assumed (as provided by Minnkota), the high-end costs become very similar to (and in some cases lower than) what the NDDH BART Determination calculated as low-end costs deemed to be reasonable. There is little difference in these high-end cost effectiveness values for Units 1 and 2. As such, EPA concludes that even without examining the concerns and problems with Minnkota's initial cost values, as discussed in comment #24 above, the existing information for the BART Determination demonstrates that SCR is cost effective. Once appropriate adjustments are made to reflect more realistic costs, these values will become even more reasonable.

(D) As noted above in comment #4, BART visibility improvement analyses must be based on the 98th percentile day results, not the 20% worst days. We do not agree that modeling based on the BART Guidelines overpredicts the visibility improvement in North Dakota.

Response:

(A) The BART Guideline, Section IV.C states "unless there are new technologies which would lead to cost-effective increases in the level of control, you may rely on the MACT standards for purposes of BART. We believe that the same rationale holds true for emissions standards developed for municipal waste incinerators under CAA Section 111(d), and for many NSR/PSD determinations and **NSR/PSD settlement** agreements." [emphasis added]. Clearly, the terms of Consent Decrees, such as the one with Minnkota, can be used in determining BART limits including startup limits that are separate from normal operation limits.

Minnkota did not include emissions from startups in their proposed BART limit because the Consent Decree indicates they must be addressed separately. Other sources have included these emissions in their proposed BART limit. Leland Olds Unit 2 has a baseline emission rate of 0.67 $lb/10^6$ Btu with a BART limit of 0.35 $lb/10^6$ Btu. The Minnkota Unit 1 baseline is 0.85 $lb/10^6$ Btu while Unit 2 is 0.79 $lb/10^6$ Btu. We have proposed a BART limit for Unit 1 of 0.36 $lb/10^6$ Btu and 0.35 for unit 2 (same as Leland Olds Unit 2). It is obvious that the Leland Olds Unit 2 limit has startups included in the rate.

The maximum 24-hour NO_x emission rates for M.R. Young that were used to determine BART applicability were 2,855 lb/hr and 5,364 lb/hr for Units 1 and Unit 2, respectively.

These values excluded startup, shutdown and malfunctions. The proposed startup limits are 2,070 lb/hr and 3,996 lb/hr for Unit 2 (24-hr average). This represents a 25-30% reduction from the baseline emission rate based on the proposed BART limits for startup. This clearly indicates there will be an improvement in visibility in the Class I areas even under the startup limits. When comparing the proposed startup limits to normal baseline emissions, it is evident that Minnkota will have to take steps to minimize emissions. Startup emissions can exceed 1 lb/10^6 Btu. The proposed startup limits represent 0.83 lb/10^6 Btu that must be averaged over the startup period. This is considerably less than the baseline emission rates (excluding SSM) which are 1.14 and 1.12 lb/10^6 Btu based on the heat input at the end of the startup period. Minnkota's justification is in Sections 3.5.2 of their analysis for each unit. The justification is virtually the same for each unit. The Department saw no reason to repeat its analysis for the similar units in its BART determination.

The Department will be making a BACT determination for the units for NO_x. That BACT determination will include startup limits. If the BACT limits are more stringent than the BART limits, the Department will reopen the Regional Haze SIP and incorporate the more stringent limits into the BART Permit to Construct.

The startup limit for Unit 2 is much higher than Unit 1 since it is a much larger unit (i.e. 477 MWe versus 257 MWe). However, the average lb/10^6 Btu emission rate during the startup is the same (0.83 lb/10^6 Btu) for both units.

Compliance with the NO_x BART limit will be determined based on the average of all hours in the 30 successive boiler operating dates except that only startups will be excluded from the 30-day rolling average. Malfunctions and shutdowns will be included. Any hours of startup will be excluded from calculating the 30-day rolling average emission rate. For startups that equal or exceed 24 hours, the average emission rate is calculated as the arithmetic average of 24 consecutive hourly emission rates. For startups that are less than 24 hours, compliance will be determined based on the arithmetic average for the duration of the startup period. The Permit to Construct has been modified to include this compliance determination method.

(B) The November 20, 1995 letter lists an URGE rating which is a three hour test. This rating does not represent a long-term rating or one that can be sustained more than three hours. The Acid Rain database lists M.R. Young Station as having a capacity of 734 MWe. The Energy Information Administration of the Department of Energy lists M.R. Young as having a summer time capacity of 697 MWe. Although Section 169A(b)(2) of the Clean Air Act does not define "total generating capacity", Section 169A(c) does discuss exempting power plants from the BART requirements if the <u>total design capacity</u> is less than 750 megawatts and it does not significantly contribute to visibility impairment. "Total design capacity" is equal to or less than the nameplate rating of the generators. In addition, the presumptive BART limits for NO_x were based on the nameplate capacity of the sources (see Technical Support Document; Methodology for Developing BART NO_x Presumptive Limits). Therefore, we believe M.R. Young Station is not subject to the BART Guidelines or the presumptive BART limits.

(C)(1) See response to Comment 25.

The 80% removal efficiency expected for SCR is in the middle of the range of efficiencies indicated in two EPA documents (see response to Comment 25) and ERG's analysis for the PGE Boardman Plant (see response to Comment 25). The BART Guideline in Step 4 states "The value selected for the design parameter should ensure that the control option will achieve the level of emission control being evaluated." The NDDH is confident that SCR + ASOFA will achieve 90% control; however, the amount of time an SCR will achieve this level of control (i.e. catalyst life) is unknown. Whether SCR will achieve 93.8% reduction efficiency over an extended period of time at M.R. Young is debatable.

The NDDH has included Minnkota's cost effectiveness and incremental cost results in our BART determination analysis. These calculations are based on 93.8% reduction efficiency. The NDDH considers the cost effectiveness and incremental costs calculated by Minnkota to be excessive over the entire range of costs.

(C)(2) The costs that are now shown represented the full range of costs provided by Minnkota. The footnote at the bottom of the cost tables has been changed to indicate that the entire cost range is provided. The NDDH has included all scenarios to show that the cost effectiveness and incremental cost is excessive regardless of the catalyst changeout schedule or whether cost should be calculated based on standalone facilities or shared facilities. Based on both the NDDH's and Minnkota's estimate cost effectiveness and incremental cost, the cost of SCR is considered excessive.

(C)(3) The cost estimate in the FLM review version of the BART determination analysis was updated by using Minnkota's cost estimate instead of one based on the cost estimate for Leland Olds Unit 2 which indicated lower costs. However, some of the discussion on cost effectiveness for M.R. Young Unit 1 from the FLM review version was not updated. This error has been corrected and EPA should not draw any conclusions regarding cost effectiveness or incremental cost effectiveness from this erroneous text.

The NDDH has included Minnkota's calculation of cost effectiveness and incremental cost in its BART determination analysis. These costs are based on 93.8% reduction efficiency. The cost effectiveness and incremental cost effectiveness are considered excessive over the entire range of costs.

Minnkota has been unable to obtain a vendor guarantee for the catalyst for either LDSCR or TESCR. This indicates that no one can predict with any reasonable accuracy the life of the catalyst. Therefore, the costs over the entire range were considered and found to be excessive.

The Department considered all five factors in determining BART for the M.R. Young Station. The incremental improvement in visibility of SCR + ASOFA versus SNCR + ASOFA is negligible (0.01 deciviews at TRNP and LWA for Unit 1 and 0.01 and 0.02 deciviews respectively at TRNP and LWA for Unit 2). This incremental improvement in visibility would cost at least $2,605,400,000 per deciview at Unit 1 and at least $2,286,700,000 per deciview for Unit 2 based on the cumulative modeling. The NDDH considers this amount of visibility improvement to be negligible and the cost unreasonable.

Even using 93.8% removal efficiency will not create much additional visibility improvement (approximately 4% additional reduction of emissions). Modeling by the NDDH indicates that SCR + ASOFA operating at 93.8% efficiency will only improve visibility 0.001 deciviews in the most impaired days when compared to SCR + ASOFA operating at 90% efficiency. The incremental visibility improvement between SCR + AOFA and SNCR + ASOFA would still be negligible.

As part of the BART process, the NDDH had to determine if LDSCR and TESCR were technically feasible. When this determination was made, the NDDH had information that a vendor guarantee could be secured for TESCR at M.R. Young Station. More recent information provided by Minnkota indicates this is not true. The uncertainty whether LDSCR or TESCR can be successfully applied at M.R. Young was weighed in the decision not to require LDSCR or TESCR. The BART Guideline states "there may be unusual circumstances that justify taking into consideration the conditions of the plant and the economic effects of requiring the use of a given control technology." Requiring the use of SCR that cannot be successfully applied at M.R. Young Station would have severe economic effects on Minnkota Power Coop.

The NDDH considers the cost effectiveness of SCR + ASOFA to be excessive. The NDDH considers the incremental cost of SCR + ASOFA versus SNCR to be excessive. This determination is applicable to both the NDDH's calculated cost values and Minnkota's values and is applicable to the entire range of costs. The NDDH considers the amount of visibility improvement of SCR + ASOFA versus SNCR + ASOFA to be negligible. The NDDH also considered the uncertainties of the technical feasibility of LDSCR and TESCR to M.R. Young Station Units 1 and 2 which is highlighted by the lack of a vendor guarantee. The NDDH stands by its determination that SCR + ASOFA is not BART.

(D) See response to Comment 4.

Comment 44: Unit 2 SO_2 Evaluation, Step 3, p. 21: We note the baseline SO_2 emissions have been revised from 16,728 tons/year upward to 18,090 tons/year in this draft. Please explain why this revision was necessary at this late date.

Response: The baseline was revised to match the expected average sulfur content for future coal. The previous baseline was based on historical data which represented coal with a lower sulfur content. The change was made in response to an FLM comment. The Department believes the use of future coal sulfur content is more consistent with the discussion on baseline emissions in the BART Guideline since it represents anticipated emissions from the unit. It did not affect the BART decision since the most efficient control option was selected both in the public comment version and the final version.

Comment 45: II.A.1.c., NO_x limits: The alternative limits for startup are not acceptable. See comment #43(A) above.

Response: See response to Comment 43.

Comment 46: II.A.1.e.: The condition that SO_2 and PM limits apply at all times, including startup, shutdown, emergency and malfunction should also apply to NO_x limits.

Response: Minnkota did not request a different limit for SO_2 or PM during startup. Therefore, we did not consider it.

Comment 47: II.A.4.b.(8): This language regarding averaging the emissions of Unit 1 and Unit 2 is not consistent with the language in the BART determination document, Section IX. The BART determination includes a formula and definition for Average Allowable Emission Rate (AER), which is not included in the permit. Please clarify.

Response: The formula for Average Allowable Emission Rate (AER) is unnecessary since averaging is only allowed if Unit 2 is basing compliance on percent reduction. Since both Unit 1 and Unit 2 have an AER of 95% reduction, the Average Allowable Emission Rate is 95%; no calculation is needed. This is specified in Condition IX.A.3(a).

Comment 48: SO_2 BART evaluation in general: NDDH notes that a circulating dry scrubber was eliminated from consideration due to excessive incremental costs. However, EPA would not find the cost effectiveness of this option ($1631/ton) unreasonable compared with other BART determinations reviewed.

Response: EPA states that the cost effectiveness of a circulating dry scrubber ($1,631/ton) is not unreasonable. However, as EPA is aware, the Department eliminated a circulating dry scrubber from consideration as BART based upon the high incremental cost of greater than $10,600/ton. It is the Department's position that both cost effectiveness and incremental cost must be considered in the analysis in accordance with long-standing EPA policy. The New Source Review Workshop Manual states, "This type of analysis should demonstrate that a technically and economically feasible control option is nevertheless, by virtue of the magnitude of its associated costs and limited application, unreasonable or otherwise not "achievable" as BACT in the particular case. Average and incremental cost effectiveness numbers are factored into this type of analysis." It is our understanding that EPA's policy (i.e., that both cost effectiveness and incremental cost should be considered) remains as stated in the Manual. The Department considered both cost effectiveness and incremental cost in accordance with long-standing EPA policy and determined that the incremental cost is excessive for a circulating dry scrubber. The Department maintains the position that the incremental cost of a circulating dry scrubber is excessive and this excessive incremental cost is a sufficient reason to eliminate a circulating dry scrubber from consideration.

Comment 49: SO_2 BART evaluations for lignite and PRB coal, pp. 8 and 22: In an effort to assess the coal quality basis for NDDH's proposed SO_2 BART determinations for Stanton, we conducted an independent analysis, using lignite and PRB coal data contained in EPA's Clean Air Markets Division (CAMD) database. The 30-day average SO_2 emission potentials (in lb/MMBtu and percent sulfur) of lignite and PRB coal are available for a wide variety of sources through CAMD, and for most (if not all) of the large coal mines in the region. We would be happy to share this information with NDDH, if desired. Since these data are readily available, we see no need for the use of a 33% multiplication factor to adjust an annual average emission rate to a 30-day rolling average emission rate.

Based upon our review of the lignite coal quality data in the CAMD database for 2007-2009, it appears that NDDH's proposed SO_2 BART limit of 0.24 lb/MMBtu when burning lignite is in the range of what we'd expect to see at a 90% control efficiency. However, we wish to note that if NDDH believes that the proposed Spray Dryer Absorber and Fabric Filter will be able to achieve 90% reduction of SO_2 emissions while burning low sulfur PRB coal, the control devices should be able to achieve greater than 90% control when burning higher sulfur content lignite coal.

Based on our review of the PRB coal quality data in the CAMD database for 2007-2009, NDDH's proposed SO_2 BART limit of 0.16 lb/MMBtu when burning PRB coal appears to be too high. The NDDH based its proposed limit on an estimate of 1.2 lb/MMBtu for the annual average SO_2 emission potential of PRB coal, then applied 90% control efficiency to yield 0.12 lb/MMBtu controlled SO_2 on an annual average, then multiplied by 1.33 to convert to a 30-day average limit of 0.16 lb/MMBtu. The NDDH's estimate of 1.2 lb/MMBtu emission potential for PRB coal was apparently based on coal sulfur content of about 0.64%. The NDDH's BART Determination document does not indicate which mines were averaged together to yield 0.64%. Data we obtained from CAMD's database for 15 of the largest PRB coal mines reveal that PRB coal typically has much lower sulfur content on a 30-day average, about half of the 0.64% used by NDDH. Our analysis of that data yielded an average SO_2 emission potential of 0.78 lb/MMBtu, on a 30-day basis, for all of the PRB coal mines together.

It appears that NDDH wishes to use the high end of a 95% confidence interval rather than an average value to set the 90% reduction limit. Therefore, we have averaged all the high end values of all the 95% confidence intervals for all the PRB mines for which we obtained data. The average of these 95% confidence intervals is 0.95 lb/MMBtu, again on a 30-day average basis. The resulting SO_2 BART limit when burning PRB coal at a 90% control efficiency would most likely be in the vicinity of 0.095 lb/MMBtu, on a 30-day rolling average.

Response: EPA states, "we see no need for the use of a 33% multiplication factor to adjust an annual average emission rate to a 30-day rolling average emission rate." The EPA provides no data to support this position and only refers to an "independent analysis" conducted by EPA. As EPA is well aware, a party (including EPA) wishing to comment during a comment period is under an obligation to submit any data that the party wishes the Department to consider. Since EPA failed to submit any data during the comment period, the Department is unable to conduct a review of EPA's data. It should be noted that EPA has been aware of the use of the 33% adjustment factor at least since August 4, 2008, did not comment on the use of the factor in EPA's October 23, 2009 comment letter and only now comments on the use of the factor. In a response to a direct request from EPA Region 8 for more information regarding the use of the 33% adjustment factor, the Department sent a December 2, 2009 email to EPA Region 8 showing that the adjustment factor is based upon actual operating data at two North Dakota facilities. EPA did not ask for further data regarding the use of the 33% factor and apparently chose instead to move directly to an “independent analysis.” Given that EPA failed to submit this “independent analysis”, the Department cannot determine if EPA even considered the Department’s data as part of the analysis.

It is common practice to establish higher short-term limits to allow for short-term emissions variability inherent to facility operations. The EPA RACT/BACT/LAER Clearinghouse contains numerous examples of short-term BACT limits which are higher than longer-term BACT limits. For example, a permit issued to Omaha Public Power District (RBLC ID NE-0031) on March 9, 2005 establishes a 3-hour average SO_2 BACT emission limit of 0.48 lb/MM Btu compared to the 24-hour SO_2 BACT limit of 0.163 lb/MM Btu and a 30-day rolling average SO_2 BACT limit of 0.095 lb/MM Btu. A permit issued to Wellington Development / Greene Energy (RBLC ID PA-0248) on July 8, 2005 establishes a 3-hour average SO_2 BACT limit of 0.234 lb/MM Btu and a 30-day rolling average SO_2 BACT limit of 0.156 lb/MM Btu. A permit issued to River Hill Power Company (RBLC ID PA-0249) on July 21, 2005 establishes a 24-hour average SO_2 BACT limit of 0.274 lb/MM Btu and a 30-day rolling average SO_2 BACT limit of 0.20 lb/MM Btu. Two examples where annual and 30-day rolling average BACT limits were established include permits issued to Associated Electric Cooperative (RBLC ID MO-0077) and Western Farmers Electric Cooperative (RBLC ID OK-0118). The permit issued on February 22, 2008 to Associated Electric Cooperative establishes a 30-day rolling average NO_x limit of 0.065 lb/MM Btu and an annual average NO_x limit of 0.05 lb/MM Btu. The permit issued on February 9, 2007 to Western Farmers Electric Cooperative establishes a 30-day rolling average NO_x limit of 0.07 lb/MM Btu and an annual average NO_x limit of 0.05 lb/MM Btu. In addition, a permit issued by EPA on July 31, 2008 for the Desert Rock facility establishes a 30-day rolling average NO_x limit of 0.05 lb/MM Btu and an annual average NO_x limit of 0.0385 lb/MM Btu. Clearly, it is common practice to establish short-term BACT limits which are higher than longer-term BACT limits.

The Department has reliable data based upon actual facilities operating in North Dakota to support the use of the 33% adjustment factor. In addition, adjustment factors (to adjust from an annual average limit to a 30-day rolling average limit) calculated from Associated Electric Cooperative, Western Farmers Electric Cooperative and Desert Rock limits are approximately 30%, 40% and 30%, respectively. These adjustment factors are very close to the adjustment factor of 33% used by the Department. Since the Department has reliable data to support the use of the 33% adjustment factor and no data has been submitted indicating that the factor is not appropriate, the Department maintains the position that the 33% adjustment factor is appropriate.

EPA states that “the control devices should be able to achieve greater than 90% control when burning higher sulfur lignite coal”; however, EPA provides no data to support this statement. The Department is aware that higher control efficiencies are thought to be attained when high sulfur coal is burned; however, EPA provides no data indicating that a higher control efficiency can be attained when burning lignite (with an assumed uncontrolled SO_2 emission rate of approximately 1.8 lb/MM Btu) as compared to PRB (with an assumed uncontrolled SO_2 emission rate of approximately 1.2 lb/MM Btu). Given that some facilities in the U.S. burn coal which results in uncontrolled SO_2 emission rates in excess of 4 lb/MM Btu, neither lignite nor PRB would be considered to be a “high sulfur coal” in comparison. Based on the available data, the Department maintains the position that a SD/FF at Stanton Station #1 is capable of an average sulfur dioxide control efficiency of 90%.

EPA states that “Data we obtained from CAMD’s database for 15 of the largest PRB coal mines reveal that PRB coal typically has much lower sulfur content on a 30-day average, about half of the 0.64% used by NDDH. Our analysis of that data yielded an average SO_2 emission potential of 0.78 lb/MMBtu, on a 30-day basis, for all of the PRB coal mines together.” The EPA submits no actual data and just refers to “data we obtained…for 15 of the largest PRB coal mines…”. EPA does not indicate which coal mines were studied and why certain mines were apparently not included in the study. EPA is under an obligation to submit any applicable data that EPA wishes the Department to consider. Unfortunately, since EPA failed to submit any data during the comment period, the Department is unable to conduct a review of EPA’s data. However, the Department did consult the U.S. Geological Survey (USGS) Coal Quality Database (available at www.usgs.gov) and found that the database currently includes over 700 samples of Wyoming and Montana subbituminous for which sulfur was analyzed. The Department has analyzed this data and has determined that the average sulfur content based on all of the samples is approximately 0.83%. In addition, the GRE BART submittal includes actual data from three mines from which GRE could potentially receive coal. The average coal sulfur contents for the three mines are 0.34%, 0.64% and 0.80%, for an average sulfur content of approximately 0.59% (on a heat input basis, the average uncontrolled SO_2 emission rate is calculated to be approximately 1.17 lb/MM Btu compared to the SO_2 emission rate assumed in the analysis of 1.2 lb/MM Btu). Based upon the available data the Department maintains the position that the uncontrolled SO_2 emission rate of 1.2 lb/MM Btu used to calculate emissions when burning PRB coal is reasonable.

Comment 50: NO_x BART evaluation: As we have commented in previous correspondence, the 45% control efficiency assumed for the alternative of combining combustion controls plus SNCR is lower than we’ve seen elsewhere. Please explain why NDDH accepted this control efficiency number from GRE. In addition, as noted above in comment #22, we have provided substantial information and evidence that all SCR technology, including High Dust SCR, is technically feasible at facilities burning North Dakota lignite.

Response: EPA states that the 45% control efficiency assumed for the alternative of combining combustion controls plus SNCR “is lower than we’ve seen elsewhere” and asks the Department to “explain why NDDH accepted this control efficiency from GRE.” EPA provides no data to support the EPA’s contention that the control efficiency “is lower than we’ve seen elsewhere.”

In the response to public comments for the Desert Rock Energy Facility dated July 31, 2008, EPA states, “A BACT determination involves judgment and balancing, and does not involve simply picking the lowest numerical emission limit or the highest observed control efficiency. The design of a wet FGD system and the resulting control efficiency depends on a variety of parameters, including the characteristics of the fuel, boiler operating data and tolerances, emission requirements…, limestone availability and quality, and economic factors.” In the Desert Rock case, EPA clearly recognizes that a number of factors must be taken into account when determining if a control efficiency is acceptable. However, in the above comment the EPA appears to ask the Department to increase an assumed control efficiency based on no data and only a vague, unverifiable statement from EPA regarding what EPA has "seen elsewhere." EPA does not even discuss if the control efficiencies EPA has "seen elsewhere" are for sources that are comparable to Stanton Station #1.

In a technical memorandum dated June 26, 2008 prepared by Eastern Research Group, Inc. (ERG) regarding the estimation of costs and impacts of NO_x control technologies applied to the PGE Boardman Plant (a coal-fired facility), ERG conservatively estimates an 18 percent SNCR control efficiency for the PGE Boardman Plant. The same memorandum references an estimate by Black and Veatch of a 20 to 25 percent SNCR control efficiency. The memorandum also states, "With regard to SNCR performance, although SNCR installations on boilers have been demonstrated to achieve between 25 and 50 percent reduction in NO_x, very large boilers (>300 MW) generally are limited to lower SNCR removal efficiencies."

The EPA Air Pollution Control Cost Manual states, "SNCR can achieve NO_x reduction efficiencies of up to 75 percent (%) in selected short-term demonstrations. In typical field applications, however, it provides 30% to 50% NO_x reduction." A table in the Manual labeled "SNCR NO_x Reduction Efficiency for Various Boiler Sizes" indicates that the SNCR reduction efficiency for the size of a boiler at Stanton Station #1 (1,800 MM Btu/hr) would be expected to be less than 40%.

GRE has described the rationale for the control efficiency selected and the EPA has not identified any actual concerns with GRE's rationale, has not provided any actual data relating to SNCR control efficiencies at Stanton Station #1 and can only offer a vague, unverified statement regarding SNCR control efficiencies. The available data indicates that a 45% control efficiency is reasonable and may in fact be on the higher end of achievable control efficiencies for SNCR applied to a coal-fired unit of the size at Stanton Station #1 as a retrofit. Given that the available data clearly indicates that the assumed 45% control efficiency is reasonable and EPA has offered no data to the contrary, the Department maintains the position that the 45% control efficiency is reasonable.

Comment 51: II.A.3., Continuous Emission Monitoring (CEM): Based on GRE's comments, this section of the permit was revised to eliminate the phrase "Main Stack" from "Unit 1 (Main Stack)" as the location for the CEM. For clarity, the permit needs to be revised to specify that the CEM location for a particular pollutant is downstream of controls for that pollutant (unless control efficiency is being measured by a combination of upstream and downstream CEMs, in which case one of the CEMs for that pollutant would be upstream of controls).

Response: The Department believes is inherently obvious that the pollutant concentration will be measured downstream of the control equipment since the CEM is meant to establish compliance with the emission limits. However, to address EPA's concern, the Department has added language to clarify that the CEMs must be located downstream of the control equipment.

Comment 52: Based on your discussions with Otter Tail Power Company, it appears that this level of minimal control is considered reasonable at this time. Therefore, even if you disagree with our other comments regarding Reasonable Progress, at least this level of NO_x control should be included in the SIP as a required Reasonable Progress control measure. As such, the permit should more closely mirror the BART permit format, including the appropriate 30-day rolling average emission limit, compliance date no later than 2018 (or sooner if reasonable), and compliance determination, monitoring, recordkeeping, and reporting requirements.

Response: The Department has found through its reasonable progress analysis that additional controls on Coyote are not reasonable. Nevertheless, in an effort to demonstrate that North Dakota continues to work with companies to make further reductions, NO_x reductions at the Coyote Station are being included in the SIP. We have relocated the write-up on the Coyote Station to Section 10.6.1, Emission Reductions Due to Ongoing Air Pollution Control Programs. Since this source is not subject to BART, we believe the Permit to Construct is appropriate. The equipment will be installed by July 1, 2018.

Comment 53: II.A.2, Compliance Date: There appears to be a typographical error in the heading – should be "Date" instead of "Data."

Response: Agreed

Subject: Estimation of Costs and Impacts of NO_x Control Technologies Applied to the PGE Boardman Plant

Date: June 26, 2008

INTRODUCTION

In response to the U.S. EPA final rule on Regional Haze and Best Available Retrofit Technology (BART) determinations, and at the request of the Oregon Department of Environmental Quality (DEQ), Portland General Electric Company (PGE) submitted their proposed BART analysis for the Boardman Plant (PGE Proposal) on November 5, 2007. The PGE proposal was prepared by Black & Veatch (B&V) and CH2M Hill.

In December 2007, Eastern Research Group, Inc. (ERG) was engaged by the DEQ to assist in the evaluation of the PGE Proposal and to conduct an independent feasibility assessment of select options for control of nitrogen oxides (NO_x) from the coal-fired Boardman Plant. ERG's scope of work (SOW), as contained in Contract 055-08, includes the following tasks:

- Task 1: Participate in a kick-off meeting in Portland with PGE, DEQ, and key stakeholder groups
- Task 2: Participate in a site visit to the Boardman Plant
- Task 3: Submit a trip report documenting the results of Tasks 1 and 2
- Task 4: Evaluate the PGE Proposal and submit memo of findings (Memo #1)
- Tasks 5 and 6: Evaluate NO_x control technologies (i.e., low NO_x burners with overfire air and selective noncatalytic reduction, low NO_x burners with overfire air and selective catalytic reduction, and other control options as identified by DEQ), and submit a memo of findings (Memo #2)
- Task 7: Participate in a meeting to discuss findings of Memos #1 and #2 with DEQ, PGE, and other stakeholder groups
- Tasks 8, 9, and 10: Prepare outline of draft report, submit draft report, and meet with DEQ, PGE, and stakeholder groups to discuss draft report
- Task 11: Participate in meeting with DEQ's BART rulemaking Advisory Committee
- Task 12: Submit final report
- Task 13: Provide "as needed" assistance to DEQ within the constraints of the project budget

Tasks 1 and 2 were completed on February 4 and 5, 2008, and the Task 3 trip report was submitted to DEQ on February 15, 2008. The Task 4 preliminary evaluation of the PGE Proposal (Memo #1) was submitted to DEQ on February 25, 2008. This evaluation focused on the NO_x control technologies that were examined by B&V for the Boardman Plant; however, the evaluation was considered preliminary because answers to most of the questions asked of PGE and B&V at the February meetings had not as yet been provided. The memo cited selective catalytic reduction (SCR) installed costs as the major issue to be resolved and most other comments were fairly minor (i.e., not likely to substantially change the BART determination).

This Task 6 memorandum (Memo #2) documents the results of ERG's complete evaluation of the PGE Proposal, as well as our own feasibility assessment of select technologies for controlling NO_x at the Boardman Plant (Task 5). Memo #2 is organized as follows:

- Summary of Methods and Findings: This section contains a brief overview of the method used by ERG to evaluate the PGE Proposal and assess the various characteristics of each NO_x control technology (i.e., performance, energy and non-air quality impacts, and cost).
- Section 1.0, Control Technologies Selected for Analysis: This section lists and describes the NO_x control technologies reviewed by ERG and contained in the PGE Proposal for the Boardman Plant. Also, the impact of the NO_x controls on the DEQ's requirements pertaining to mercury for Boardman is discussed.
- Section 2.0, ERG's Cost Estimation Methodology: This section describes the inputs and outputs of the cost estimates developed by ERG using the CUECost model. Conclusions are presented regarding the appropriateness of this method for use on Boardman's NO_x control retrofit options.
- Section 3.0, Comparison of PGE Proposed Costs and ERG Costs Estimates for NO_x Control: This section compares the results contained in the PGE Proposal for the range of NO_x controls, to ERG's estimates. This section addresses the significant issue of how best to estimate SCR installed costs for the Boardman Plant in view of widely varying costs that results from various approaches.
- Section 4.0, Conclusions: This section provides ERG's findings with regard to the PGE Proposal for the Boardman Plant's NO_x and mercury control technologies.

SUMMARY OF METHODS AND FINDINGS

Based on the experience of ERG's NO_x control expert and relevant literature, ERG evaluated the performance and energy and non-air quality impacts of the NO_x control technologies identified by DEQ for this analysis, and evaluated in the PGE Proposal for the Boardman Plant, including (combinations of): new low NO_x burners (NLNB), advanced overfire air (AOFA), selective noncatalytic reduction (SNCR), and selective catalytic reduction (SCR). Our findings are as follows:

- With regard to the performance of NLNB with AOFA, ERG acknowledges that the unusual furnace internals at the Boardman Plant (i.e., wing or division walls extending well below the boiler nose) will limit the effectiveness of these controls in reducing NO_x, and finds that the B&V estimate of 0.28 lb/MMBtu does not seem unreasonable.

- With regard to the performance of existing low NO_x burners (LNB) with overfire air (OFA) and SCR, reductions of 70 to more than 90 percent have been documented from recent installations; however, these are based on units that operate mainly during the ozone season and that have substantial opportunity for off-season maintenance and catalyst cleaning. The impact of existing LNB with OFA and SCR at the Boardman Plant under year-round operation would need to be considered in selecting a permit level.
- With regard to SNCR performance, although SNCR installations on boilers have been demonstrated to achieve between 25 and 50 percent reduction in NO_x, very large boilers (>300 MW) generally are limited to lower SNCR removal efficiencies. The Boardman Plant is large and has division walls, noted above, that limit upper furnace mixing. In Memo #1, ERG expressed concern that SNCR might not achieve the 20 to 25 percent that B&V was predicting for Boardman. B&V has since requested a more detailed assessment of the unit by Fuel Tech, the country's leading SNCR vendor and has reduced the estimated performance to18 percent to be conservative.
- With regard to energy and non-air quality impacts, ERG finds that there are no significant impacts from existing/new LNB, AOFA, or SNCR. In general, ERG agrees with the PGE Proposal that SCR has three (potential) adverse impacts as compared to SNCR: an SCR unit requires at least 36 times as much electricity to operate as SNCR; disposal of spent catalysts create hazardous waste (although ERG believes evolving catalyst management practices may minimize this impact); and anhydrous ammonia releases create an additional accidental release hazard. In some cases, utilities have chosen to avoid this hazard by generating ammonia "on demand" from urea, although this involves added capital and operating expense.

ERG's method for evaluating cost of the NO_x control technologies included use of the CUECost estimation program. The CUECost program is widely accepted and used by the utility industry and government agencies for estimating costs for controls applied to coal-fired power plants. While ERG believes that CUECost is appropriate for estimating cost for relatively small construction projects (e.g. NLNB, AOFA and SNCR retrofits for coal-fired power plants), we do not believe that CUECost accurately reflects installed costs for major construction projects, such as SCR and flue gas desulfurization (FGD), for reasons that evolved through this study. These findings are described below.

From the outset, the majority of ERG's attention and effort focused on the probable installed cost of SCR at the Boardman Plant. In our preliminary evaluation (Memo #1), ERG believed that the SCR installed cost estimate provided on page D-9 of the PGE Proposal overstated the likely cost (2007 cost-basis), possibly by as much as a factor of two. We focused on the SCR installed cost because:

- SCR is widely and successfully applied on Powder River Basin (PRB) coal units throughout the country;
- SCR is effective in reducing NO_x to very low levels; and
- SCR represents a substantial increase in installed cost as compared to SNCR (which is the BART technology proposed by PGE).

For quite some time, the power plant NO_x control community has used \$100/kW as a rule-of-thumb installed cost for SCR installed on coal-fired power plants. This was based on costs reported for some early installations in the 1990s and early cost studies by the U.S. Environmental Protection Agency (U.S. EPA) and others. As we started this analysis of the PGE Proposal, ERG was aware of three literature papers that addressed SCR installed costs (Hoskins, 2003; Cichanowicz, 2004; Marano and Sharp, 2006) with cost-basis years of 2002, 2003 and 2005, respectively. These papers provided evidence that the $100/kW rule-of-thumb did not correspond to the costs being experienced by utilities installing SCR in the 2002–2005 timeframe. In an initial conference call with DEQ personnel, ERG expressed an opinion that SCR installed costs for Boardman may be on the order of $150/kW or about one half the $309/kW that was contained in the PGE Proposal.

Section 3.0 of this memo contains a discussion of three avenues of analysis that ERG has pursued to evaluate the probable installed cost of SCR at Boardman. These are:

- Bottom-Up installed cost using the CUECost Model with the Chemical Engineering Construction Cost Index for 2007 applied.
- Top-Down literature values obtained from the SCR installed costs as reported in various Internet and subscription sources.
- A current B&V "real" project cost that ERG was permitted to examine (under terms of a confidentiality agreement) in the B&V offices in Overland Park, Kansas.

ERG supplemented these cost sources with literature papers and relevant study findings concerning the general escalation in heavy construction cost resulting from the world-wide commodities bubble and construction labor shortages.

The CUECost program generates an installed cost of $70/kW to $130/kW; however, we feel this does not represent the probable cost of SCR applied to the Boardman Plant.

The top-down literature values analysis is based on a large number of data points including 33 SCR project installed costs provided by PGE and B&V in an April 6, 2008 submission to DEQ. Although there are many data points in this dataset, the quality of the individual points is difficult, and in some cases impossible, to assess. Nonetheless, all of these sources do point to a rapid escalation in SCR installed costs since 2004. ERG analyzed the 2007 cost-basis data by eliminating the three highest and three lowest cost projects and one project that was known to be very dissimilar to the Boardman Plant characteristics. The remaining nine projects range from $207/kW to $267/kW, with an average of $227/kW. ERG believes that this is a reasonable representation of 2007 costs of large SCR installations under normal retrofit conditions.

ERG examined the actual cost data (i.e., both the bid cost developed for the project proposal and the actuals from the B&V project accounting system) for a recent SCR project performed by B&V. The total installed cost for this project was $221/kW on a 2007 cost-basis. This project cost falls near the middle of the costs resulting from the analysis of the 2007 top-down literature values described above and thus provides confirmation that the range of $207/kW to $267/kW is reasonable.

Certain retrofit conditions at the Boardman plant tend to increase the installed cost, and others tend to reduce costs. The fact that some boiler modifications will be needed (due to the high flue gas temperature at the economizer outlet) that are not typical of SCR retrofit projects, tends to offset some of the cost-lowering factors present at the Boardman Plant. With all of these factors taken into consideration, ERG concludes that the Boardman Plant SCR installed cost would be at the high end of the \$207/kW to \$267/kW range cited above (a detailed analysis of this finding is in Section 3.4 of this memo). However, since no detailed design of the Boardman Plant SCR has been carried out, there is a fairly broad uncertainty band associated with all of these cost estimates.

Table 1 of this memo provides a side-by-side comparison of the costs for all NO_x control technologies evaluated in the PGE Proposal, and by ERG using the research and methods described above. Differences in costs range from less than 1 percent (for NLNB) to 100 percent for existing LNB with OFA and SNCR. Differences between PGE and ERG cost estimates for SCR range from 24 percent (SCR with existing LNB and OFA) to 27% (SCR with NLNB and AOFA).

1.0 CONTROL TECHNOLOGIES SELECTED FOR ANALYSIS

DEQ directed ERG to review several specific NO_x controls for potential use at the Boardman Plant. These controls, listed below, were also contained in the PGE Proposal and initially reviewed by ERG in Memo #1 (submitted to the Oregon DEQ on February 25, 2008):

- New low NO_x burners (NLNB)
- NLNB with advanced overfire air (AOFA)
- Existing LNB with OFA and selective catalytic reduction (SCR)
- Existing LNB with OFA and selective noncatalytic reduction (SNCR)
- NLNB with AOFA and SCR
- NLNB with AOFA and SNCR

The remainder of this section discusses the performance (i.e., percent reductions and emission rates in pounds per million BTU [lbs/MMBtu]) and energy and non-air quality environmental impacts for each of the NO_x controls. Also, the potential impacts of each NO_x control on DEQ's existing mercury control requirement for the Boardman Plant are discussed.

1.1 Performance of NO_x Controls

New Low NO_x Burners

Improvements to LNB design since development of the first generation of LNBs have achieved an additional 20 to 40% reduction in NO_x in comparison to first generation LNBs. The PGE Proposal indicates that the Boardman Plant was issued a construction permit in 1977. As part of the permit, PGE utilized first generation low NO_x burners (LNB) in combination with overfire air (OFA) to reduce NO_x emissions. This combination of controls is discussed below.

New Low NO_x Burners with Advanced Overfire Air

Since the early to mid-1990s, boosted overfire air systems (referred to as advanced overfire air or AOFA) began to be operated. This OFA system can be installed over the existing wind boxes for retrofit installations. Advanced OFA systems add air ports to several walls of the furnace, in addition to just the burner walls. Due to fan systems and extra air ports, more flow can be diverted than in the original OFA system. The extensive placement of ports in the AOFA system also allows air to be diverted to a greater area of the furnace interior. The NO_x removal efficiency of the AOFA system ranges from 15 to 25 percent compared to the baseline case. New LNBs in combination with AOFA systems have been demonstrated to achieve NO_x emission levels as low as 0.15 lbs/MMBtu for some wall-fired boilers firing PRB coal. However, for reasons discussed below, ERG does not believe that 0.15 lbs/MMBtu is achievable at the Boardman Plant.

There are a number of instances of NLNB/AOFA retrofits on units that burn PRB coal where the resulting NO_x emission level is reported to be 0.15 lbs/MMBtu. An examination of the individual units involved shows that all but one of the units are tangential-fired with very low pre-retrofit NO_x emission levels. The single wall-fired unit is discussed in a paper prepared by the vendor, Riley Power (Penterson, 2003). The specific unit is not identified in the paper, nor is the owning utility identified. The paper does discuss some characteristics of the unit which are not typical of most wall-fired boilers. Specifically, when the unit was originally started up, it was determined that it could not be fired at its intended full rating. Sixteen of the original burners were removed resulting in a substantial derating and a very low initial NO_x of 0.30 lbs/MMBtu. The initial NO_x at Boardman (0.43 lbs/MMBtu) is more than 40 percent higher than the unit described in the Penterson paper and the achievement of 0.15 lbs/MMBtu at Boardman Plant by retrofitting NLNB and AOFA does not appear feasible.

Also, the furnace internals at the Boardman Plant appear to be rather unusual in that the wing (or division) walls extend well below the boiler nose. More typically, in-furnace pendant pressure parts would extend down to the nose. The Boardman Plant upper furnace has wing-walls that suspend from the furnace roof to about midway down to the furnace floor. They appear also to extend from the front wall to about midway to the back wall and will present problems both in getting good mixing of the AOFA and possible rapid tube corrosion due to the strongly reducing flue gas conditions, if deep-staging is attempted in the Boardman furnace.

The non-typical situation at Boardman Plant will, in the opinion of ERG, limit the effectiveness of NLNB and AOFA in reducing NO_x. Determining exactly how much reduction could be achieved would require detailed computational fluid dynamics (CFD) modeling; however, the B&V prediction of 0.28 lb/MMBtu does not seem unreasonable.

Low NO_x Burners with Overfire Air and Selective Catalytic Reduction

Recent installations on utility boilers have shown that SCR can achieve 70 to more than 90 percent efficiency, and NO_x emission levels as low as 0.05 lbs/MMBtu. Similarly, SCR in combination with LNB with OFA or NLNB with AOFA have been demonstrated to achieve NO_x emissions as low as 0.05 lbs/MMBtu. Most of this experience is with ozone-season units that have a substantial opportunity for off-season maintenance and catalyst cleaning; therefore, the impact of year-round operation would have to be considered in selecting a permit level for the Boardman Plant.

Low NO_x Burners with Overfire Air and Selective Noncatalytic Reduction

SNCR installations in combination with LNB with OFA or NLNB with AOFA on utility boilers have been demonstrated to achieve between 25 and 50 percent reduction. The reduction percentage that can be achieved is extremely unit-specific and fairly large units generally achieve reductions at the low end of the range. ERG has expressed concern that high upper furnace temperatures at the Boardman Plant, and the effect of the wing walls on upper furnace mixing mentioned earlier, might severely limit reductions achievable at the plant. During a meeting at B&V offices in Kansas on April 24, 2008, B&V indicated that they have had Fuel Tech (a leading SNCR vendor) conduct further examination of the Boardman unit. Fuel Tech confirmed that there was an appropriate injection location (in the upper backpass, rather than the usual upper furnace location), and that 25 percent reduction is feasible. B&V said that they were assuming 18 percent in their estimates to be conservative.

1.2 Energy and Non-Air Quality Environmental Impacts

Existing/New Low NO_x Burners, Existing/Advanced Overfire Air, Selective Noncatalytic Reduction

There are no significant energy or non-air quality environmental impacts from use of existing or NLNB, existing or AOFA, or SNCR.

Selective Catalytic Reduction

The PGE Proposal cites three energy and non-air quality environmental impacts for which SCR is disadvantaged when compared to SNCR:

- B&V calculates that the SCR unit will require 36 times as much electric power as SNCR, due to the additional fan power needed to overcome the catalyst bed pressure drop. ERG believes that this figure may be low. CUECost generates a differential of about 100 times for the same SCR-to-SNCR comparison.
- The PGE Proposal cites the disposal of spent catalyst as a hazardous waste as being a non-air quality environmental impact. This may be of little significance, based on evolving catalyst management practices. Catalyst regeneration processes potentially allow for reuse of the catalyst modules for several cycles, making the disposal cost and environmental impact much less than earlier industry estimates.
- The PGE Proposal cites the additional accidental release hazard associated with anhydrous ammonia (for SCR) versus urea solution for SNCR. Although the remote location of Boardman makes this less of an issue when compared to urban and suburban power plants, nevertheless, there is added hazard for plant personnel and the few people that may live or be present in the path of an ammonia plume from the plant. This hazard can be remedied for a price. Today, there are commercially available systems that convert urea to ammonia "on demand", with no significant ammonia inventory present at the facility at any time. As noted, this is an additional capital and operating cost for the SCR installation. It should also be noted that ammonia is a fairly common industrial chemical and refrigerant and there are established safeguards and procedures for its handling and storage.

In general, ERG agrees with the PGE Proposal assessment of these impacts, at least qualitatively.

1.3 Mercury Control Technologies

Additionally, the effect of the NO_x controls on reducing mercury emissions was also evaluated. PGE proposes to retrofit a fabric filter downstream of the existing electrostatic precipitator (ESP) to enhance the control of particulate matter at the Boardman Plant. The PGE Proposal states that this technology selection was driven, in part, by the future need to control mercury emissions with dry sorbent injection. This approach is consistent with the approach taken throughout the industry for power plants burning PRB coal. Because mercury contained in PRB coal flue gas is not readily oxidized by SCR catalysts for subsequent collection in a flue gas desulfurization (FGD) system, virtually all near-term mercury control for PRB units will be through the use of activated carbon injection (or injection of enhanced activated carbon). In a very recent study by The Shaw Group (Wedig et al., 2008) published in the May 2008 issue of Power Magazine, the authors identified a total of 51 PRB plants (8 new and 43 retrofit) that have committed to mercury control, all proposing activated carbon injection.

None of the other NO_x controls considered (i.e., NLNB, AOFA, SNCR) would have any impact on the Boardman baseline mercury emissions. Also, for reasons stated in the previous paragraph, capture of mercury in an FGD system (wet, dry, or semi-dry, would be very small and Boardman, like other PRB coal-fired units, will need to rely on some form of carbon injection for mercury control.

2.0 ERG'S COST ESTIMATION METHODOLOGY

The U.S. EPA's BART guidance (www.epa.gov/air/visibility/pdfs/guidelines_2005_6_24.pdf) recommends: "The basis for equipment cost estimates also should be documented, either with data supplied by an equipment vendor (i.e., budget estimates or bids) or by a referenced source (such as the OAQPS Control Cost Manual, Fifth Edition, February 1996, EPA 453/B-96-001)." Consequently, ERG reviewed the procedures in the available cost estimation methodologies, the OAQPS Cost Manual, and also the CUECost estimation program to determine the most appropriate methodology for providing capital and annual costs. Initially, ERG decided that the CUECost estimation program was more appropriate because it provided costs separated into elements which could be compared to the specific cost elements used by B&V in developing the PGE Proposal. Also, the CUECost program is widely accepted and used by the utility industry and government agencies to provide cost estimates, and it is tailored to air pollution controls applied to coal-fired power plants.

The remainder of this section describes the CUECost input data used by ERG, and provides our conclusions related to CUECost's ability to predict "real world" costs for projects requiring major heavy construction (e.g., SCR) as compared to smaller projects (e.g., NLNB, AOFA, and SNCR) that do not require major structural work or large process equipment. Based on our conclusions, we deviate from a CUECost approach when preparing an independent estimate for SCR installed cost; this is explained in detail below in Section 3.4 of this memo.

2.1 Cost Algorithm Inputs

The CUECost program provides cost estimates for new LNB, SCR, and SNCR. The cost factors for AOFA provided in an earlier analysis conducted by ERG for the Western Regional Air Partnership (WRAP) were used to calculate the capital costs. The WRAP report indicates that in 2005, the installed capital cost for AOFA was $8.80/kW. The total capital investment for the combinations of NO_x controls using AOFA were calculated by adding the AOFA capital costs.

Attachment A lists the inputs necessary to run the CUECost program for NO_x control technologies, and the rationale for use of the different inputs. The attachment also provides the inputs used in the analysis and the source of the input data. After reviewing the PGE Proposal CUECost inputs, ERG concludes that most of the inputs that were used for PGE's CUECost runs were appropriate for the analysis. Consequently, where possible, we used inputs provided by PGE for our assessment. Attachment B contains detailed cost outputs from CUECost for NLNB, AOFA, SNCR, and SCR. Attachment C shows a detailed comparison of the PGE and ERG CUECost estimates for total capital investment of SCR, which is a main area of disagreement (see Section 3.4 for more details on this comparison).

The CUECost program was last updated in 2002. For the outputs to be relevant, ERG escalated the costs to 2007 using Chemical Engineering magazine cost factors.

2.2 Conclusions Regarding the Use of CUECost for the Boardman Analysis

As discussed later in detail in Section 3.4 of this memo, ERG's investigation of SCR installed costs for the 2007 cost-basis year has led us to the conclusion that CUECost does not provide "real world" costs for SCR in the current environment for major construction projects. Similarly, based on a study prepared for the National Lime Association (Sargent and Lundy, 2007) and a study by Cichanowicz for the Utility Air Regulatory Group (Cichanowicz, 2007), there is good evidence that FGD (i.e., another technology requiring heavy construction) installed costs have escalated at an unprecedented rate since about 2004. CUECost, even when inflation-adjusted by applying the current Chemical Engineering Construction Cost Index, appears to produce installed costs that are well below those that appear in the recent literature. However, for relatively "smaller" projects, such as LNB, AOFA, and SNCR retrofits, we believe that estimates developed using CUECost are reasonable.

ERG was not able to determine why CUECost seems unable to generate costs corresponding to current experience; however, Cichanowicz, et al. (Cichanowicz et al., 2006), speculated that early SCR installations may have been misleading due to under-design (that resulted in failure to meet performance objectives) and selection of favorable retrofit units for early installations. Also, some features now considered more or less standard (e.g., large pitch catalyst, popcorn ash screens, static mixers, and provision of a great deal of sootblower capability) were not part of early system designs. Finally, vendors were clearly positioning for the surge of installations in 2002, 2003 and 2004, and substantial cost overruns may have been absorbed by the vendors and constructors, and would not necessarily be reported by the utilities or appear in the literature. In the recent worldwide high-demand environment for industrial construction services and equipment, the opposite effect may be taking place, where engineering firms, constructors and equipment manufactures are bidding with high profit margins and large contingency factors, driving up installed costs.

Although ERG is convinced that CUECost fails to provide "real world" installed costs for major construction projects such as SCR retrofits, we are not able to necessarily extend this to projects that do not require extensive "construction" (e.g., extensive foundations and structural works, ductwork modifications, etc.) and projects where retrofit issues do not heavily influence installed costs. For smaller projects such as NLNB, AOFA and SNCR, largely because we have no evidence to the contrary, we have used CUECost results escalated to 2007 by applying the 2007 Chemical Engineering Construction Cost Index.

3.0 COMPARISON OF PGE PROPOSED COSTS AND ERG COST ESTIMATES FOR NO_x CONTROL

This section compares the PGE proposed costs with the ERG costs for the NO_x control technologies selected for this analysis. Table 1 summarizes the total capital cost in units of $/kW from the PGE Proposal and as estimated by ERG for each NO_x control technology. A discussion of each of the comparisons is provided below for NLNB (Section 3.1), NLNB with AOFA (Section 3.2), SNCR (Section 3.3), and SCR (Section 3.4).

3.1 NLNB Comparison

The capital cost estimates for NLNB from ERG's CUECost run differs by less than 1% of the estimate provided by PGE. This difference was not considered significant and, therefore, not analyzed further.

3.2 NLNB with AOFA Comparison

The difference in total capital cost of NLNB with AOFA between the PGE Proposal and ERG's estimates is due to PGE's use of handling and erection cost factors that are higher than those in CUECost to estimate direct installation costs. The handling and erection factor (50 percent of the purchased equipment cost) is approximately 20 to 30 percent higher than cost factors used in CUECost and in EPA's OAQPS Cost Manual. These additional costs then propagate further when calculating Indirect Costs and Total Capital Investment. The PGE Proposal included costs for the following ancillary equipment: neural network system, NO_x monitoring equipment, water cannon, and modulating orifice for burners. These additional cost items add approximately $8/kW to the total installed cost.

ERG agrees that certain upgrades such as neural networks and burner air controls are part of general system upgrades that allow NLNB with AOFA to achieve and maintain optimum performance. Also, PGE reported that slagging has been a recurring problem when the current OFA system is operated continuously. Water cannons have been used extensively for PRB units throughout the country. ERG's cost is based on a combination of the CUECost result ($28/kW) and the cost of the ancillary equipment noted above ($8/kW) for a total of $36/kW. The PGE Proposal cost is $53/kW, or about 47% higher.

Table 1. Comparison of PGE Proposed Costs and ERG Costs for NO_x Control at the Boardman Plant

Control Technology	Cost Estimate in $/kW		% Difference	Notes
	PGE	ERG		
NLNB	18	18	< 1%	CUECost and PGE estimates are essentially the same.
NLNB with AOFA	53	36	47%	PGE cost is much higher than CUECost results. PGE added equipment items not included in CUECost. ERG agrees that these items are warranted and that the probable cost is about $8/kW. This cost was added to the CUECost result to arrive at the ERG estimate.
Existing LNB with OFA + SNCR	28	14	100%	ERG cost is based on CUECost and confirmed by leading SNCR vendor public statement. ERG does not know the basis of PGE's estimate and cannot duplicate it.
NLNB with AOFA + SNCR	81	50	62%	Cost is based on adding the NLNB with AOFA cost to the SNCR cost, above.
Existing LNB with OFA + SCR	309	250	24%	ERG cost is based on the high end of the range of costs ($207/kW to $267/kW) that ERG found to be reasonable based in the analysis described in Section 3.4 of this memo.
NLNB with AOFA + SCR	362	286	27%	Costs are based on summing the cost of "stand-alone" SCR with the cost of NLNB/AOFA. Probably costs should be slightly lower because of reduced inlet NO_x.

ERG does not have information that would support the higher erection factor used by PGE as compared to the CUECost default values. However, we do note again that there has been rapid escalation in construction costs in recent years for SCR that does not seem to be captured by CUECost using the Chemical Engineering Cost index.

3.3 SNCR Comparison

For the option of using the existing LNB with OFA along with a new SNCR, PGE's Proposal indicated that CUECost was used to calculate costs of the SNCR system. However, PGE's CUECost outputs could not be duplicated using the inputs provided in the PGE Proposal. Insufficient information was provided to fully assess the reason for the differences. The costs estimated by PGE for reagent storage, handling, injection and controls were $5,100,000 compared to the CUECost output of $1,730,000. Air heater modifications calculated by PGE were $2,835,000 compared to the CUECost output of $1,400,000. These additional costs then propagate further when calculating indirect costs and total capital investment.

Fuel Tech's Dr. Bill Sun, a longtime expert on SNCR, recently placed SNCR installed costs at \$5 to \$20/kW (Sun, 2007). The CUECost estimate of \$14/kW falls comfortably within the range indicated by Fuel Tech. This cost would apply to both the existing LNB with OFA and NLNB with AOFA, as SNCR capital costs are relatively insensitive to initial NO_x emissions levels. The PGE Proposal contains an installed cost of \$28/kW for SNCR (which we cannot reproduce); this is at least 50 percent higher than the CUECost estimate for SNCR.

3.4 SCR Comparison

ERG reviewed the SCR installed cost contained in the PGE Proposal. The review has involved a number of information-gathering steps and discussions with DEQ, PGE and B&V. The following activities have taken place since the start of the project in January 2008:

- January 18 - After a brief review of the BART Proposal, ERG and DEQ conducted a conference call to plan initial steps. During this call ERG gave its initial reaction to the PGE Proposal and cited the SCR installed costs as, in our opinion, well above costs appearing in the literature.
- February 4 - ERG attended the Stakeholder Meeting at Stoel Rives LLP. B&V presented the main points of the BART Proposal and ERG provided 14 questions in writing. These questions were combined with dozens of other questions raised by the stakeholders attending the meeting.
- February 5 - ERG attended a tour of the Boardman Plant.
- February 15 - ERG submitted a trip report covering the February 4 meeting and the February 5 plant tour.
- February 15 - ERG received and reviewed the B&V response to ERG question #2, which asked for the plant, economic, and NO_x inputs used for the CUECost model runs that were used in the PGE Proposal. In some ways, the response confused these issues rather than clarifying them, since the data and discussion in the response did not correspond to the discussion in the PGE Proposal (i.e., different inlet NO_x, different percent removal).
- February 25 - ERG submitted Memo #1 to DEQ, discussing the ERG review of the PGE Proposal. SCR installed cost was identified as the primary concern. Most other comments were relatively minor.
- March 23 - ERG received and reviewed the PGE/B&V responses to 101 questions that were recorded at the February 4 and 5 meetings.
- April 6 - ERG received and reviewed a B&V discussion of current and historical SCR installed costs. This submission included installed costs for 33 SCR projects (both single unit and multiple unit projects) with the cost-basis year, unit size, and installation year. These were obtained from the open literature and subscription sources. Both actual completed projects and future (estimated cost) installations are included.
- April 24 - ERG attended a meeting and discussion at B&V offices in Kansas. At this meeting, B&V presented a detailed cost estimate for a current SCR project that is similar enough in size as to be relevant to the potential Boardman installed cost.

The primary issue is: ***How to estimate SCR installed cost for the Boardman Plant in view of widely varying costs that result from various sources and approaches?***

We examined three fundamentally different costing approaches to address this issue:

- Bottom-up installed cost using the CUECost Model
- Top-down literature values
- B&V "real" project cost

In addition, we examined the general escalation of construction costs due to the commodities bubble and labor shortages. These approaches and the general escalation of construction costs as related to SCR are discussed in detail below.

Bottom-Up Installed Cost Using the CUECost Model

CUECost is a widely-used, U.S. EPA-developed cost model for air pollution controls applied to coal-fired power plants. When the model is run with Boardman-specific technical inputs, the default economic inputs, a "difficult" retrofit factor and escalated to 2007 dollars, the result for Boardman is about $100/kW. Since the developers of CUECost specifically caution that the level of detail involved results in a plus-or-minus 30 percent estimate, the CUECost estimate for the Boardman Plant would actually be $70/kW to $130/kW. However, a number of recent studies of actual installed costs for completed installations and estimates for near-term future installations call into question the direct use of CUECost in today's construction environment. For reasons noted below, it is ERG's opinion that the CUECost model does not generate "real world" SCR installed cost estimates.

Top-Down Literature Values

There are three fairly recent literature papers that address SCR installed costs (Hoskins, 2003; Cichanowicz, 2004; Marano and Sharp, 2006). In a paper prepared for the Utility Air Regulatory Group, Cichanowicz compiled SCR installed costs from the same three papers (Cichanowicz, 2007). Also, Internet searches produced a number of other anecdotal examples of recent plant-specific costs. Although there are many data points in this dataset, the quality of the individual points is difficult, and in some cases impossible, to assess. Nonetheless, all of these sources do point to a rapid escalation in SCR installed costs since 2004.

In their April 6 submission, B&V compiled installed costs for 33 SCR projects, including both single unit and multiple unit installations. The average SCR installed cost for the 2007 projects was $242/kW, and B&V concluded that these data are consistent with their Boardman Plant estimate of $309/kW when the proposed Boardman boiler modifications, at $65/kW, are added. (Note: the Boardman Proposal [at page D-9] includes the cost of NLNB and AOFA along with the SCR cost, resulting in a total of $362/kW for the combined technologies.)

ERG examined the 33 individual data points (installed cost, cost-basis year) and determined that several of the critical (2007 cost-basis) data points are skewed somewhat to the high side. For example, 6 of the data points for 2006 represent projects at Progress Energy's Ancolote and Crystal River plants. The data for cost-basis year 2007 contains these same projects, escalated by 70 percent based on a blanket statement by a Progress Energy official that the cost of new air pollution controls have "jumped 70% from their 2006 submission" (to the Florida Public Service Commission). An examination of the source document shows that the 2006 submission actually contained estimates with a 2005 cost-basis. Also, the implied 70 percent escalation from 2006 to 2007 is in conflict with a statement by Kentucky Utilities (before the Kentucky Public Services Commission) that the installed cost estimate of SCR for Ghent Unit 2 had increased by 21 percent from 2006 to 2007. The 70 percent escalation figure is also inconsistent with a number of other papers (see below) that address the general cost escalation for various types of utility construction in the current environment.

Two of the critical 2007 cost-basis data points were contained in the BART proposals for Gerald Gentleman Units 1 and 2 ($334/kW) and Nebraska City Unit 1 ($376/kW). In both cases, the estimate was provided by architectural and engineering firm HDR. The estimates were described as based on 2002 vendor quotes for major equipment, adjusted for capacity (the quotes were not for the specific plants involved), escalated to 2007 (by applying a 68 percent escalation factor), doubled to account for construction costs, and multiplied by a 25 percent contingency factor. ERG does not accept that these very crudely developed costs represent useful data in evaluating cost of the Boardman Plant retrofit.

Finally, an examination of the year-to-year escalation implied by the 33 data points provided by B&V calls into question the quantitative use of the data (though it is certainly useful in a qualitative sense.). For the B&V dataset, the year-to-year changes in historical average installed costs are:

- 2002 to 2003 = +80 percent
- 2003 to 2004 = +76 percent
- 2004 to 2005 = +25 percent
- 2005 to 2006 = -37 percent
- 2006 to 2007 = +62 percent

Obviously, these year-to-year variations, including a drop in cost of 37 percent from 2005 to 2006, are an indication that these data are not useful in any given year in a quantitative sense. They do, however, support the contention that the last several years have seen construction cost escalation that is significantly above the general consumer inflation rate in recent years.

To more closely examine these data in a quantitative sense, ERG eliminated the three highest (including the afore mentioned HDR estimates) and three lowest estimates contained in the 16 projects which make up the 2007 basis-year data. We also eliminated the WE Energies' Oak Creek Units 5 and 6 project since these are small, tail-end systems. The remaining nine projects are fairly tightly grouped, providing some comfort that they represent "typical" installations, rather than outliers. **These projects range from $207/kW to $267/kW, with an average of $227/kW.** The fact that the average is very close to the B&V "real" project cost discussed below tends to confirm that this range ($207/kW to $267/kW) is a reasonable representation of 2007 costs of large SCR systems and normal retrofit conditions.

B&V "Real" Project Cost

At an April 24, 2008, meeting at the B&V offices, an ERG engineer was presented with detailed estimates for two very recent B&V SCR installations. After examining the "specifics" of one of the projects, ERG concluded that it was too different (i.e., much smaller, hot-side ESP, low-dust SCR) to provide a relevant data point for the Boardman Plant retrofit. The second plant was sufficiently close in "specifics" to the Boardman Plant to be relevant. Clearly, the cost details were based on B&V actual costs, and were not prepared specifically for ERG's visit. They correspond roughly to 2007 dollars since the project start was mid-2006 and it is now just wrapping up. B&V provided the estimate for this same unit, reformatted to correspond to the line items on page D-9 of the PGE Proposal.

The B&V "real" project cost of $221/kW that was provided in the D-9 format exhibits some line-by-line differences when compared to the Boardman Plant SCR estimate prepared by B&V for PGE. These differences include higher total purchased equipment costs, lower total direct installation costs, and a much higher cost for site preparation and buildings at the Boardman Plant. The most significant difference the Boardman Plant estimate and the B&V "real" project cost is the $65/kW added to account for boiler modifications to reduce the SCR flue gas inlet temperature. Also, the Boardman BART Proposal SCR estimate includes an additional $53/kW for NLNB with AOFA. ERG believes that the benefit of the NLNB with AOFA system (i.e., lower SCR inlet NO_x) is not properly reflected in the PGE Proposal's SCR cost estimate.

In spite of some of the differences cited above, ERG believes the "real" project cost data that were reviewed at the B&V offices on April 24, 2008, support the PGE/B&V position that CUECost, when run with default values and an escalation factor, does not generate "real world" SCR installed costs for a 2007 cost-basis year.

General Escalation of Construction Costs due to the Commodities Bubble and Labor Shortages

In addition to the three costing approaches described above, ERG considered a fourth factor in analyzing the Boardman Plant SCR estimate contained in the PGE Proposal. In their April 6, 2008 submission of historical SCR installed cost data, B&V included two recent articles that deal with rapidly escalating construction in the utility industry (Chupka and Basheda, 2007; Schimmoller, 2007). Although these articles do not address SCR specifically, they do give a clear sense that construction costs are escalating at a rate well above historical norms. In a report prepared for the National Lime Association, Sargent and Lundy pegged the recent escalation of FGD installed costs at 25 percent per year (Sargent and Lundy, 2007) (Note: FGD retrofits involve the same type of major structural work, large process equipment and retrofit issues that are present with SCR installations.). As noted earlier, Kentucky Utilities estimated an increase of 21 percent for the Ghent Unit 2 SCR cost from a 2006 to a 2007 cost basis. All of these are indications that the effect of world demand for construction materials, equipment, and labor are exerting a strong upward pressure that has impacted SCR installed costs in the U.S.

Summary of SCR Cost Analysis

It is ERG's opinion, based on a distillation of the three cost approaches discussed above and the general rapid cost escalation environment, that the 2007 installed costs for SCR range from $207/kW to $267/kW, barring any extremely favorable or unfavorable site-specific conditions.

In the Boardman case, there are factors that would tend to push costs toward the high end of the range and other factors that would tend to reduce costs. Some of the factors that tend toward higher cost include:

- Use of PRB coal (as compared to bituminous coal);
- The Boardman Plant's remote location and its impact on labor availability and cost;
- The higher-than-normal structural bridge needed to span the ESP; and
- The boiler modifications needed to adjust inlet flue gas temperatures.

Some of the cost-reducing factors include:

- A unit size that is large enough to provide economy of scale, but small enough to fit the catalyst box between the unit and the stack;
- A single-unit plant with much clear space around the rear of the plant; and
- (Importantly) the low inlet NO_x and low removal efficiency specified in the PGE Proposal.

Although some of the site-related factors are favorable (e.g., clear space, single unit plant), the major complicating factor is the boiler modifications for flue gas temperature adjustment, which B&V places at $65/kW. ERG believes, based on conversations with B&V personnel, that B&V has not analyzed this cost in detail (nor has ERG). ERG notes that, in general, all SCR retrofits require ductwork modifications at the rear of the boiler and in many cases, an economizer bypass is included, thus some of the costs associated with fitting the SCR into the boiler/airheater train are already contained in SCR estimates. Anecdotal information on pressure part replacement projects (from the Internet) gives us the impression that the B&V estimate is high, but in the absence of design and cost details, ERG is unable to quantitatively assess this. ERG does agree that some significant cost is involved and that it would tend to push the Boardman installed cost toward the upper end of the range cited above ($207/kW to $267/kW). Bearing in mind the broad uncertainty band associated with all of the estimates, ERG selected a "round number" cost of $250/kW as our Boardman Plant SCR installed cost.

4.0 CONCLUSIONS

The following are ERG's conclusions regarding the NO_x control technologies in the PGE Proposal:

- Appropriate NO_x technologies were included in the analysis.
- The control level estimate for NLNB with AOFA is reasonable. PGE and B&V enlisted Fuel Tech to more closely examine the Boardman Plant and confirm SNCR performance. The resulting B&V estimate of 18 percent control is reasonable. SCR units can achieve control to the 0.05 lbs/MMBtu level, but not necessarily meet a 0.05 limit. Most of SCR experience is with ozone-season units that are afforded significant off-season opportunity for maintenance and catalyst cleaning. The impact of year-round operation would have to be considered in selecting a permit limit for Boardman.
- NLNB with AOFA costs are reasonable.
- ERG finds that the B&V's estimated installed cost for SNCR is high by at least 50 percent. ERG's estimate (based on CUECost) is $14/kW versus the B&V cost of about $28/kW.

- ERG finds that the contention by PGE and B&V that SCR installed costs have escalated extremely rapidly in recent years is supported by a number of literature sources. For reasons not fully clear, CUECost does not capture this recent surge in installed cost, even when the most recent Chemical Engineering Cost Index is applied.
- ERG's analysis of the 2007 cost for retrofitting SCR at the Boardman Plant is based on literature information and on data provided by PGE and B&V. We find a cost of about $250/kW versus the PGE and B&V estimate of $309/kW to be reasonable in view of recent similar installations and literature estimates.
- Future mercury control is appropriately addressed by the proposed fabric filter. Since mercury oxidation across an SCR and subsequent collection in an FGD system is relatively ineffective for PRB coal, mercury control at Boardman will likely entail activated carbon injection (or some other dry sorbent) followed by collection in a fabric filter. The other NO_x technologies considered (NLNB, AOFA, SNCR) will not influence the Boardman baseline mercury emissions or future mercury controls.

MINNKOTA POWER COOPERATIVE, Inc. and SQUARE BUTTE ELECTRIC COOPERATIVE

FOLLOWUP RESPONSES TO PRESENTATION and NDDH REQUEST FOR ADDITIONAL INFORMATION SUPPLEMENTAL NOx BACT ANALYSIS STUDY MILTON R. YOUNG STATION UNIT 1 and UNIT 2 REGARDING SCR ECONOMIC FEASIBILITY

February 11, 2010

North Dakota Department of Health's Environmental Health Section, Division of Air Quality has requested[1] that Minnkota Power Cooperative Inc. ("Minnkota" or "MPC") provide additional information clarifying the written response submitted December 11, 2009[2] that provided detailed and comprehensive cost data following the NDDH's and U.S. EPA's reviews of the Best Available Control Technology (BACT) Analysis Study – Supplemental Reports[3] submitted on November 12, 2009 for control of nitrogen oxides (NO_X) emissions from existing Unit 1 and Unit 2 at Milton R. Young Station (MRYS).

Burns & McDonnell (B&McD) was retained by MPC as an independent consultant to perform the referenced 2006 NO_X BACT Analysis Study[4] of Minnkota's Unit 1 and Square Butte Electric Cooperative's Unit 2 at the Milton R. Young Station in accordance with the requirements of a Consent Decree (CD)[5]. Burns & McDonnell also performed the November 2009 Supplemental NO_X BACT Analysis Study and generated the referenced reports for each MRYS boiler in response to the NDDH's request[6] to see Steps 3 and 4 of the BACT analysis process[7] include low-dust and tail end SCR alternatives, assuming that they are technically feasible to apply at MRYS as NDDH has recently advised[8].

Information supplementing the previously-provided detailed breakdown of capital costs and operation and maintenance costs for hypothetical applications of low-dust and tail end SCR alternatives, and their subsequent presentation to NDDH, are attached.

---

[1] See Reference number 1, January 11, 2010.

[2] See Reference number 2, December 11, 2009.

[3] See Reference number 3, November 12, 2009.

[4] See Reference number 4, October 2006.

[5] See Reference number 5, April 24, 2006.

[6] See Reference number 6, July 15, 2009. SCR technology is considered technically infeasible by Minnkota for application at MRYS per the October 2006 NOx BACT Analysis Study report and subsequent submittals in response to comments by the NDDH, EPA, DOJ, and other parties, including the November 2009 Supplemental NOx BACT Analysis Study reports.

[7] See Reference number 7, October 1990.

[8] Ibid Reference number 6, July 15, 2009. SCR technology is considered technically infeasible by Minnkota for application at MRYS per the October 2006 NOx BACT Analysis Study report and subsequent submittals in response to comments by the NDDH, EPA, DOJ, and other parties, including the November 2009 Supplemental NOx BACT Analysis Study reports.

NOx BACT Analysis Study Supplemental Reports:

NDDH Request #1: How were the SCR reactors sized and the catalyst volume determined and what target NOx control efficiency was used to size the catalyst? How was the cost of the catalyst determined?

BMcD Response:

The same SCR system supplier that is providing the low-dust SCR equipment for the WE Energies South Oak Creek project in Wisconsin was asked to provide a budgetary equipment proposal for both low-dust and tail end SCR arrangements for each unit at MRYS. A lignite coal analysis (proximate, ultimate, and coal ash) and process design basis (boiler fuel heat input rates, excess air percentages, flue gas volumetric flows, temperatures and gas species contents) were included with the request. An assumed inlet and outlet NOx concentration was also provided, with a nominal 85% reduction from 0.5 lb/mmBtu requested. This SCR system supplier sized the SCR reactor, the SCR gas-to-gas heat exchange equipment (SCR GGH), and related ductwork. The initial catalyst charge for each reactor was included in the lump-sum equipment price proposal. The SCR system supplier did not disclose the specific volume of catalyst to be provided nor the specific manufacturer or type of catalyst (i.e. honeycomb, plate, etc.). Due to the proprietary nature of this SCR conceptual design and budgetary equipment pricing effort, this work was performed by the SCR system supplier with the understanding that it was confidential. Refer to Burns & McDonnell's response to NDDH Request #7 for additional information.

Two SCR catalyst suppliers provided budgetary replacement catalyst quotes, including catalyst volume, catalyst pitch, catalyst type, and arrangement of catalyst modules, based on preliminary process design provided by an SCR process design consultant. The design used for these catalyst supplier proposals was based on 90% overall NOx reduction across the SCR system. The catalyst suppliers also provided cost proposals for the replacement catalyst. One supplier provided a cost of replacement catalysts in terms of $\$/m^3$. Due to the proprietary nature of this SCR reactor sizing and budgetary catalyst pricing effort, this work was performed by the SCR catalyst suppliers with the understanding that it was confidential. Refer to Burns & McDonnell's response to NDDH Request #7 for additional information.

NDDH Request #2: Anhydrous ammonia appears to be a less expensive reagent than urea for the SCR system due to local availability. A justification must be supplied for electing urea over anhydrous ammonia.

BMcD Response:

Aqueous urea solution was selected because of health and safety issues related to the use of ammonia, including site constraints involving over-the-road transport, on-site unloading and storage. MRYS does not have rail access, and is adjacent to a lake used for condenser cooling water and process water supplies. Public access to the lake is allowed. Anhydrous ammonia and aqueous ammonia are classified as hazardous chemicals per Clean Air Act Section 112 (r). This requires extensive emergency planning. Transport and handling of ammonia is restricted by the United States Department of Homeland Security and the Department of Transportation through the Rail Security Act. The U.S. EPA has determined that a toxic radius of a spill to be between 5 and 7 miles for anhydrous ammonia and 1 to 2 miles for aqueous ammonia[9].

NDDH Request #3: Support must be provided for the catalyst cleaning/replacement outage periods. This should include an explanation of the method used to estimate the outage time and clarification whether the outage time includes the regular outage period.

BMcD Response:

Burns & McDonnell and Minnkota queried SCR catalyst suppliers, process design consultants, utility construction and maintenance contractors, and utility personnel at U.S. coal-fired plants with operating SCRs to provide input into the estimation of time associated with catalyst installation into the empty (spare) layer of the reactor, and to remove dirty catalyst and install fresh catalyst in its place. The responses indicated that there is a broad range of experiences based on limited amounts of user and vendor data on this issue. The range of experience is due to the site-specific conditions and design-specific features of the reactor catalyst access doors' locations and sizes, module arrangement, hoisting equipment, staging areas and platforms, labor availability and familiarity. The general lack of data is due to the relative newness of many SCR installations currently operating at coal-fired powerplants in the United States that have not accumulated significant operating time and so have not required significant numbers of catalyst changeouts.

Catalyst replacement activities by current coal-fired powerplant users are typically scheduled during major boiler outages that are 18-36 months apart. The SCR catalyst changeout is usually not a schedule-critical activity during such outages. The catalyst changeout time required depends on how many modules are involved, and whether a single shift of personnel or multiple shifts per day are engaged in the work.

For the hypothetical application of low-dust and tail end SCR technologies at MRYS, most of the catalyst changeouts were assumed to coincide with boiler fireside cleaning outages, which are historically approximately 4 days in duration, three or four times per year, depending on the boiler involved. Because of the use of high pressure water to remove boiler deposits during these cleanings, the air exhausted from the boilers through the flue gas ductwork to the chimneys during these times contains moisture and particulate.

---

[9] See Reference 8.

Catalyst vendors have advised that this air stream is not suitable for passing through an SCR reactor filled with catalyst. This will require an SCR reactor bypass to be provided for use during these outages.

Before catalyst changeout operations can begin, the large volume of catalyst and supporting structural steel must be cooled down sufficiently to allow personnel to safely enter the reactor to gain access to remove any ash accumulations. The means and equipment required to remove the catalyst depends on the specific reactor design and module arrangements. The specific time and equipment requirements for catalyst changeouts are normally developed after the specific reactor and module details are established.

The SCR Cost Estimate study assumed that reactor isolation dampers and reactor maintenance bypass ductwork dampers would be required to avoid contamination of the catalyst by the air/water/particulate stream, and allow the reactors to be cooled while being isolated from the normal flue gas path to the chimney. The time estimated for catalyst installation into the empty (spare) layer of the reactor was 16 shifts, which, assuming two shifts per day, would be 8 days. The time estimated to remove dirty catalyst and install fresh catalyst in its place was 24 shifts, which, assuming two shifts per day, would be 12 days. The time assumed for reactor cooldown was previously estimated as 48-60 hours, which would elapse during the first half of the boiler cleaning process[10]. After the fresh catalyst is in place, and the reactor access doors closed, the entire volume of fresh and dirty catalyst remaining in the reactor must then be heated to above the moisture dewpoint to avoid possible moisture condensation during boiler startup. This would involve use of the supplemental catalyst outage heating system, not the flue gas reheat system nor flue gas from the boiler. Burns & McDonnell estimated that post catalyst changeout outage time will extend approximately 36-48 hours until the boilers are ready to begin the startup process to return to service.

The November 2009 Supplemental NOx BACT Analysis study assumed 1168 total hours and 1126 total hours of outage time per year associated with MRYS Unit 1's hypothetical application of low-dust and tail end SCR technologies (Scenario "B"), respectively. This is 980 hours and 938 hours of outage time in addition to the 188 hours of outage time per year assumed for advanced separated overfire air alternative. Assuming three catalyst layer changeout outages per year for Unit 1, this works out to be approximately 13 extra days per outage. Unit 2's Scenario "B" assumed 1415 total hours of outage time for either hypothetical application of low-dust and tail end SCR technologies. This is 1234 hours of outage time in addition to the 181 hours of outage time per year assumed for advanced separated overfire air alternative. Assuming four catalyst changeout outages per year for Unit 2, this works out to be approximately 13 extra days per outage.

---

[10] See Reference 9, March 15, 2007, pages 12-14.

The November 2009 Supplemental NOx BACT Analysis study assumed 401 total hours and 443 total hours of outage time per year associated with MRYS Unit 1's, and 387 total hours and 428 total hours of outage time per year for Unit 2's, hypothetical application of tail end and low-dust SCR technologies (Scenario "A"), respectively. This is 213 or 256 hours of Unit 1 outage time and 206 or 247 hours of Unit 2 outage time in addition to the 181 hours of outage time per year assumed for advanced separated overfire air alternative. Assuming one catalyst changeout outage every two years for each Unit 1 and Unit 2, this works out to be approximately between 8.6 and 10.7 extra days per outage, depending on the boiler and SCR technology studied.

The catalyst changeout outage times assumed in the November 2009 Supplemental NOx BACT Analysis study for MRYS Unit 1 and the similar study for MRYS Unit 2 are expected to be extensions to the boiler cleaning outages. Note that the estimated annual number of days for catalyst changeout outages is in addition to outage times included in the Advanced Separated Overfire Air alternative, which is also relative to baseline operation which include downtime for boiler cleanings. We believe the outage durations and frequency are reasonable assumptions to use for the purposes of showing possible economic outcomes that could result from the hypothetical application of low-dust and tail end SCR technologies at MRYS.

NDDH Request #4: The indirect capital costs associated with the project appear to be high. A detailed explanation of the estimation method must be supplied.

BMcD Response:
Burns & McDonnell used standard estimating practices to estimate direct, installation, and indirect capital costs for MRYS Unit 1's and Unit 2's hypothetical application of low-dust and tail end SCR technologies. To establish the context of estimated indirect costs, we note that several major assumptions were used by Burns & McDonnell in developing the capital cost estimates of the hypothetical applications of low-dust and tail end SCRs at Milton R. Young Station. These assumptions include the following:

- A multiple (parallel prime) contracting approach was selected (as opposed to single "turnkey" or Engineer-Procure-Construct contract). Although this approach may increase the project execution risk to the Owner, the execution risk is considered manageable. This contracting approach was recommended because it allows early award of major equipment procurements to allow detailed design engineering to proceed expeditiously to meet the project schedule, and offers the greatest flexibility for the Owner (Minnkota) to be involved in key decisions regarding design.
- Project will be executed to achieve completion in 2016 for Unit 2 and 2017 for Unit 1. It was assumed that the project will be executed with skilled workforce resources sufficient to meet the target project execution schedule while minimizing overtime. No additional overtime is included to accommodate a compressed work schedule.

Indirect Costs:

- Escalation based on historical data and Burns & McDonnell experience was assumed to average 5% per year for equipment, 9% per year for materials and 5% per year for labor. See additional general description of escalation included below.
- Contingency was calculated at 20% overall (10% for pricing and 10% for scope). Contingency was applied to Total Direct Capital Costs plus Indirect Capital Costs such as Engineering and Field Support, Construction Management and related indirects, Startup Expenses, and Cost Escalation during Project Execution. Owner Contingency was estimated at 7%. See additional general description of contingency included below.
- A performance bond is included for all subcontract work at the rate of 1.5% of the estimated project contract costs.
- Sales tax on construction consumables is included. No other tax is included.
- Owner will provide a builder's risk policy for the project. Cost for this is included in the estimate of Owner's costs.
- Interest During Construction (IDC) is included in the Owner's costs at 6% per year, assuming project execution-based monthly expenditures.

Escalation:

An estimate for escalation of project costs has been included in the capital cost estimate. Escalation of construction labor, materials, and indirects was estimated based on historical data and Burns & McDonnell experience.

Escalation of construction labor was estimated to be approximately 5% annually throughout the project. This estimate of escalation was based on the average increase in craft labor costs for the United States combined with known union labor contract costs in the next few years. The average annual escalation of union contracts for skilled and common labor rates over the last ten years in North Dakota has been approximately 5.0% per year.

Escalation of equipment and materials is included in the project estimate at a rate of 5% per year for equipment and 9% per year for materials. Since January 2004, steel pricing experienced rapid escalation equating to a nearly a 100% increase in rebar and structural steel costs, then dropped in late 2008 and early 2009. Within the past 6 months, steel prices have again started to rise. Pipe and electrical commodities have also seen a high overall escalation during this time, followed by a decline in late 2008. Due to this volatility, equipment and material suppliers have been providing pricing with short bid validity.

Contingency:

This project involves a significant amount of retrofit work in the existing plant. The SCR Cost Estimate study did not perform a thorough review of existing conditions and interfaces with the new work. It is anticipated that the scope of work will increase as unknown conditions are discovered during project execution. A contingency of 20% of the overall project costs is included in the project cost. Of this 20%, 10% covers accuracy of the pricing of the equipment and materials (commodities), and 10% covers omissions from the defined project scope. This contingency is not intended to cover changes in the general project scope (i.e. addition of buildings, addition of redundant equipment, addition of systems, etc.) nor major shifts in market conditions that could result in significant increases in contractor margins, major shortages of qualified labor, significant increases in escalation, or major changes in the cost of money (interest rate on loans).

In addition to the project contingency, an additional owner contingency is included to cover owner general project scope additions. Based upon the amount of preliminary design and project definition completed, a 7% scope contingency to cover such potential changes is included. However, this contingency level depends on the probability of additional scope and is typically determined by the Owner (Minnkota).

NDDH Request #5: Support must be supplied for the cost of natural gas and electricity.

BMcD Response:
Burns & McDonnell used estimated long-term average natural gas unit cost for the economics of conventional and fuel-lean gas reburn alternatives' annual operating costs included in the 2006 NOx BACT Analysis Study reports for MRYS Unit 1 and Unit 2. The annual cost of auxiliary power consumed by air pollution control equipment and the value of electric generator output not able to be sold ("lost") due to inability to produce electricity during outages related to the air pollution control equipment associated with particular control alternatives were also calculated. The long-term average unit costs for natural gas and electricity were provided by Minnkota. Burns & McDonnell's recent review of the forecast power industry's natural gas unit cost forecasts from 2006 confirm that the number used in the original NOx BACT Analysis Study calculations and reports submitted in October 2006 are reasonable, given the uncertainty and variability that is common with such forecasts.

In the November 2009 Supplemental NOx BACT Analysis study reports, Burns & McDonnell assumed the economics of hypothetical application of low-dust and tail end SCR technologies at MRYS should be also based on the same unit costs used for the 2006 NOx BACT Analysis study reports.

NDDH Request #6: More details, including calculations, must be supplied to justify the pressure drops and parasitic loads associated with the SCR configurations.

BMcD Response:
Burns & McDonnell used estimated flue gas pressure drops provided by the SCR supplier for the SCR reactor, and gas-to-gas heat exchangers (GGH), in the development of new induced draft booster fans' performance requirements and the alternatives' economics of hypothetical application of low-dust and tail end SCR technologies at MRYS for Unit 1 and Unit 2 in the November 2009 Supplemental NOx BACT Analysis study reports. The estimated flue gas pressure drops of the flue gas ductwork, which would be incurred upstream and downstream of the low-dust and tail end SCR reactors and GGHs, were calculated using a proprietary spreadsheet.

For low dust SCR cases, new ductwork would be connected downstream of the existing induced draft fans' outlets and a new booster fan for each reactor would follow the GGH outlet after the SCR reactor, discharging to the existing flue gas desulfurization (FGD) system absorber inlet duct[11].

In tail end SCR cases, new duct connections downstream of the existing induced draft fans' outlets would divert flue gas before the FGD absorbers' inlet ducts, through the hot side of the FGD GGH then back to the FGD absorber inlet duct. Additional duct connections downstream of the existing FGD absorbers' outlet ducts would reroute flue gas through the cold side of the FGD GGH, then to the cold side of the main (SCR) GGH upstream of the flue gas reheat section in the SCR reactor. After the reactor, flue gas would pass through the hot side of the main (SCR) GGH, continue to the new induced draft booster fans, and be discharged back to new duct connections near the existing inlets to the chimneys[12].

Horsepower required to drive the fans to produce pressure needed to overcome the cumulative ductwork and SCR equipment pressure losses for full load (maximum continuous rating) and "test block" flue gas flows was calculated from budgetary booster fan equipment quotes, which included preliminary pressure rise versus flow and mechanical efficiency curves, from two fan vendors. The horsepower required for the volumetric gas flow and pressure rise was then converted into electrical kilovolt-amperes (kVA) and kilowatts (kW) in order to calculate auxiliary power loads. An annual average load factor was applied, which was then multiplied by the assumed hours of annual operation to determine the annual megawatt-hours (MW-h) of consumed auxiliary power due to the SCRs' induced draft booster fans.

---

[11] See attached sketch for low-dust SCR equipment and ductwork conceptual arrangement.
[12] See attached sketch for tail end SCR equipment and ductwork conceptual arrangement.

The parasitic loads associated with the SCR alternatives studied were determined by identifying known power-consuming auxiliary equipment serving the new air pollution control equipment. Estimates of design horsepower or kVA, based on vendor quotes or similar projects where information is available, were generated. Conversion to kW along with application of an annual average load factor resulted in estimated average annual auxiliary power loads, which were summed together to establish the total parasitic load. Annual megawatt-hours (MW-h) of consumed auxiliary power due to the various SCR cases studied were calculated by multiplying the total parasitic load by the assumed hours of annual operation.

The table below provides the results of these calculations.

Pressure Drop and Fan Power Calculation Results

Parameter	U1 LD	U1 TE	U2 LD	U2 TE
FGD GGH (hot side) pressure drop, in. w.g.	--	2.7	--	1.87
FGD GGH (cold side) pressure drop, in. w.g.	--	2.7	--	1.87
SCR GGH (cold side) pressure drop, in. w.g.	2.3	2.7	1.74	1.98
SCR reactor/catalyst press. drop, in. w.g.	2.0	2.0	2.0	2.0
SCR GGH (hot side) pressure drop, in. w.g.	2.3	2.7	1.74	1.98
SCR flue gas ducts/dampers/connections pressure drop, in. w.g.	5.4	6.2	4.5	6.3
Booster Fan Static Pressure Rise / Total Pressure[1] (Inches W.G.)	12.0 / 13.51	19.0 / 21.33	10.0 / 11.50	16.0 / 18.23
Booster Fan Motor Horsepower[2]	5000	7000	3500	5000
Load kVA / Demand kVA[3]	5000 /4500	7000 /6300	3500 /3150	5000 /4500
Quantity of Fans, capacity per fan, each case	One (1) x 100%		Two (2) x 50%	

1- Booster fan static pressure rise is the sum of the duct and SCR equipment pressure drops. Total fan pressure includes fan static pressure rise plus additional pressure rise required to overcome pressure drops within the fan equipment. These numbers do not include additional fan capacity (margin) above the amount required for full load (maximum continuous rating or MCR) operation, which allows for factors that reduce actual performance over sustained periods of running. Static pressure rise and Total pressure numbers are preliminary; final design may require values higher or lower than those shown.

2- Motor horsepower is greater than fan mechanical horsepower, and is based on available size larger than "Test Block" horsepower. Mechanical horsepower takes into account fan mechanical efficiency at the stated operating condition. Fans are sized based on mechanical efficiency and additional capacity (margin) above the MCR condition, referred to as "Test Block". The test block flow margin is 15% per fan, the test block pressure rise margin is 32.25% (1.15^2) above MCR values stated above. Test block fan mechanical efficiency is approximately 0.8. Fan Mechanical Horsepower = flue gas volumetric flow (actual cubic feet per minute) multiplied by pressure rise in inches w.g. divided by (6536 x efficiency). Fan efficiency varies with flow and pressure rise; values based on estimates/vendor quotes for full load (maximum continuous rating or MCR) conditions.

3- Horsepower (motor rating) is approximately equal to Connected Load kVA; Connected Load kVA x Estimated Annual Average Demand factor = Demand Load kVA.

Hypothetical applications of low-dust and tail end SCR technologies included estimates of auxiliary electrical power usage. It is important to note that some alternatives identified between 88 and 109 electricity-consuming items supplying or serving each SCR reactor system. Several pieces of auxiliary equipment with significant electrical power loads were included. These are: sootblowing air compressors with dryers; instrument/service air compressors with dryers; seal air fans for SCR reactor inlet and outlet flue gas isolation dampers; SCR flue gas reheat burner combustion air fans; drive gearboxes for rotary gas/gas heat exchangers; urea-to-ammonia dilution air/combustion air fans; auxiliary equipment service building ventilation/heating/lighting; and urea feed pumps. The instrument/service air and sootblowing air compressors are significant but necessary to supply dry compressed air used by equipment dedicated to control, maintain, and provide catalyst cleaning media for the SCR systems.

NDDH Request #7: All vendor correspondence related to SCR reactor sizing, catalyst volume, NOx control efficiency, catalyst cost, catalyst replacement schedule, and catalyst guarantees should be provided. This includes the original requests submitted to vendors and analyst [catalyst] suppliers by Minnkota and its consultants. This must also include the description of the gas stream that was supplied to the vendors.

BMcD Response:
Information responsive to this request by Minnkota, Burns & McDonnell and the SCR system supplier and SCR process design consultant, catalyst vendors, and flue gas particulate characterization consultant is being submitted (see Enclosures). Documents that include information considered as "trade secrets" per the NDDH's Air Pollution Control rules are being submitted and marked "confidential" (see Enclosures).

Minnkota developed agreements with the catalyst suppliers and flue gas particulate characterization consultant engaged in this effort, and has a general services agreement with Burns & McDonnell, which covers work done by the SCR system supplier and SCR process design consultant. Information provided under Enclosure C is considered non-confidential, and includes information for which no claim is being made for confidentiality, along with an index and summary of the information submitted which is suitable for release to the public. Enclosure D includes documents claimed to contain trade secrets which are requested to be treated as confidential, along with an affidavit stating how and why the information fulfills the conditions of confidentiality per the NDDH's Air Pollution Control rules describing this confidentiality procedure.

NDDH Request #8: Data must be provided for the temperature gradient of the regenerative heat exchanger to justify the reheat calculations. This must be provided for the both LDSCR and TESCR. The 600°F temperature for the reheated flue gas must be justified.

BMcD Response:

The preliminary design temperatures for the hypothetical applications of low-dust and tail end SCR technologies shown in the table below were calculated by the SCR process consultant. The temperature data tabulated below for the Unit 1 low dust (LD) case include corrections identified by the SCR process consultant as described further in the response to NDDH Request #11.b. The SCR system supplier, which provided pricing of SCR equipment, including GGHs for low-dust and tail end SCRs, did not provide estimates of the GGHs' process performance.

SCR Process Design Temperatures

Parameter	U1 LD	U1 TE	U2 LD	U2 TE
FGD GGH (hot side) inlet temperature, °F	--	335	--	331
FGD GGH (hot side) outlet / FGD Absorber Inlet temperature, °F	--	(1)	--	(1)
FGD GGH (cold side) inlet/ FGD Absorber Outlet temperature, °F	--	142	--	143
FGD GGH (cold side) outlet temperature, °F	--	150	--	151
SCR GGH (cold side) inlet temperature, °F	335	150	331	151
SCR GGH (cold side) outlet temperature, °F	535	520	535	520
Flue Gas Reheat Burner outlet / SCR Ammonia Injection Grid/Reactor inlet temperature, °F	580	563	580	563
SCR GGH (hot side) outlet temperature, °F	380	199	380	197
FGD Absorber Outlet temperature, °F	142	142	143	143

1- The temperature of the FGD GGH hot side outlet (discharges to FGD Absorber Inlet) was not provided by the SCR process consultant. It would be less than 330°F.

As can be seen in the table above, the flue gas is reheated by natural gas to either 580°F for low-dust SCR cases or 563°F for tail end SCR cases. Natural gas heat input rates used in the November 2009 Supplemental NOx BACT Analysis study reports assumed these flue gas temperatures. These preliminary process design temperatures have not been confirmed pending final design by the gas/gas heat exchanger manufacturer. The catalyst vendors recommended that the catalyst be designed for (able to withstand continuous exposure to) 600°F service operating temperature. The capacity of the reheat burner equipment was not specifically provided by the SCR system supplier, but was expected to be capable of raising the flue gas up to the recommended service temperature.

NDDH Request #9: A comparison of the SCR costs at M.R.Young Station versus PSE&G Mercer Station and We Energies Oak Creek Station should be provided or an explanation why such a comparison is not possible or inappropriate. We recognize that each plant has unique characteristics and there will be some design differences from plant-to-plant, but those differences should not necessarily dismiss making general comparison of costs unless there are unique or extenuating circumstances which would preclude a general cost comparison.

BMcD Response:

A BACT analysis is performed on a case-by-case, site-specific basis. It is inappropriate to compare the capital costs associated with the low-dust SCR installation at Mercer Station, or at South Oak Creek Station, against those developed for the hypothetical applications of low-dust and tail end SCR technologies at MRYS. Site conditions, boiler firing type, type and characteristics of fuels burned and resulting flue gas emissions and ash produced, and the limited amount of NOx reduction required for those referenced low-dust SCR cases that were not required to represent BACT, make the comparison not relevant to MRYS.

NDDH Request #10: Provide additional clarification and technical justification regarding Minnkota's determination that the units at MRYS are boiler limited and cannot generate additional steam for flue gas reheating purposes.

BMcD Response:

The steam turbine-generators at MRYS have a given output (gross megawatts) based on steam pressures, temperatures and flow rates related to the boilers. Removing high pressure/high temperature steam to use for flue gas reheating will directly cause a reduction in electrical output. This output reduction cannot be compensated for by increased boiler steam generation without unreasonable consequences. The boilers generate steam based upon their fuel heat input (firing) rates and capacities to absorb the heat created from the fuel combustion. The efficiency of converting fuel heat to steam to megawatts (heat rate or Btu per gross kilowatt) is limited by many factors. Fuel characteristics and boiler capacity are factors that impact heat rate (efficiency) that are not easily changed in the positive direction. The current fuel quality coming from the adjacent mine is not within the original design parameters of the boilers.

Because of the firing type (cyclone) and characteristics of North Dakota lignite burned and resulting flue gas emissions and ash produced at MRYS, the amount of fouling of the heat-absorbing surfaces within the boiler system is severe. These fouling conditions cause high exit flue gas temperatures that eventually reach the maximum limit recommended for maintaining the integrity of the air preheaters. This is indicated by the time-temperature graphs previously provided[13] and repeated below. The rate of boiler surface fouling increases significantly as more coal is fired, especially at maximum sustainable firing rates.

Due to the sticky character of the ash deposits, an "arsenal" of sootblower and water lance equipment is employed by Minnkota in an attempt to reduce the rate of fouling accumulations during boiler operations and remove these deposits during frequent boiler outages. These boiler cleaning outages occur every three to four months depending on the specific unit and the fuel quality delivered during the period. If the firing rate is increased to generate more steam for other heating purposes, the frequency of the cleaning outages must be increased. If the accumulated deposits are not removed, the frequency of the cleaning outages must be increased or the firing rates must be reduced and thus reduce the steam and electrical output of the boilers and steam turbine-generators. There is not "excess steam available for flue gas reheating" that would allow Minnkota to avoid reduced annual power generation.

NDDH Request #11: There appear to be several discrepancies in the documents that must be addressed including:

a. **The catalyst volume for Unit 2 (p. 4-23) is listed as 256 m^3 per reactor or 512 m^3 per layer. This is 4-5 times more than Unit 1 yet Unit 2 is not twice as large. Please verify the Unit 2 catalyst volume.**

At page 4-23, the words "per reactor" should be deleted from the sentence describing Unit 2's catalyst volume. This will be shown on an "Errata Sheet" attached to this document.

For Unit 2, the total initial volume was 768 cubic meters for three layers, or 256 cubic meters per layer, based on catalyst vendor input. Subsequent installation of 342 cubic meters for the fourth layer was assumed, also based on catalyst vendor input. Total initial volume plus first fill of spare layer equaling 1110 cubic meters is for two SCR reactors for each case studied for Unit 2. The correct catalyst volumes were used in the annual operating and maintenance cost calculations that are a portion of the levelized total annual costs for NOx control alternatives provided in the referenced November 2009 Supplemental NOx BACT Analysis study reports.

The conceptual design of Unit 1 Low-Dust SCR Reactor, and Tail End SCR Reactor as provided by the catalyst supplier included in each layer a total of 104 catalyst modules (8 x 13 arrangement). There is one SCR reactor for each case studied for Unit 1. The conceptual design of Unit 2 Low-Dust SCR Reactor, and Tail End SCR Reactor included in each layer a total of 91 catalyst modules per reactor (7 x 13 arrangement). There are two SCR reactors for each case studied for Unit 2.

b. **The reheat for Unit 2 for TESCR is listed as 48.11 MMBtu/hr per reactor and for LDSCR is 45.55 MMBtu/hr per reactor. The differential between TESCR and LDSCR is much less than for Unit 1 (60.3 MMBtu/hr and 31 MMBtu/hr). Please explain this difference.**

The preliminary process design calculations were reviewed for the hypothetical applications of low-dust and tail end SCR technologies for Unit 1 and Unit 2. It was determined from this review that the temperature rise for the Unit 1 LDSCR flue gas reheat system was incorrectly assumed to be 25 degrees F instead of 25 degrees C (equivalent to 45 degrees F). The corrected 45 degrees F temperature rise for the Unit 1 LDSCR flue gas reheat system is shown in the table included with the response to NDDH Request #8. The correct natural gas heat input rate for Unit 1's low-dust SCR cases is 54.5 MMBtu/hr (instead of 31 MMBtu/hr).

The discovery of the underestimate of Unit 1's low-dust SCR flue gas reheat fuel requires revision to the MRYS Unit 1 November 2009 Supplemental NOx BACT Analysis study report for "Scenario A" and "Scenario B" cases. A revised version of the referenced November 2009 MRYS Unit 1 Supplemental NOx BACT Analysis Study report document and the December 2009 response document is being submitted with the corrected numbers and recalculated control costs (see Enclosures). The flue gas reheat fuel rates and costs assumed for the hypothetical applications of Unit 1's tail end and Unit 2's low-dust and tail end SCR alternatives included in the November 2009 Supplemental NOx BACT Analysis study reports will not change.

The temperature rise for the Unit 1 TESCR, Unit 2 LDSCR, and Unit 2 TESCR flue gas reheat systems are also shown in the table included with the response to NDDH Request #8. These are all preliminary numbers that would require confirmation after final cold-side outlet design temperatures are established by the FGD and SCR gas/gas heat exchanger manufacturer.

c. The capital costs for the "stand alone" SCR (p.3 of attachments to December 11, 2009 submittal) do not total correctly. Please check the numbers and revise the documents as necessary.

The numbers for "Pricing Contingency" shown in the table that provided "Estimates of Total Capital Investment for Low Dust and Tail End Selective Catalytic Reduction Alternatives Best Available Control Technology – Supplemental Analysis Stand Alone" cases submitted on December 11, 2009 were incorrect. They should match the "Scope Contingency" numbers above the "Pricing Contingency" line in the table. A revised version of the referenced document is being submitted containing the table with corrected data (see Enclosures).

d. The flue gas reheat burners and fans appear to be included in both "SCR system equipment" and "Auxiliaries" cost estimates (see p.4 of attachments to December 11, 2009 submittal, footnotes 1 and 3). Please check this and revise the documents as necessary.

There are two systems of natural gas-fired burners associated with each alternative studied for hypothetical application of low-dust and tail end SCR technologies in the November 2009 Supplemental NOx BACT Analysis study reports. The "flue gas reheat burner equipment" is correctly included as part of the "Purchased Capital Equipment SCR System Equipment" item (1) (a) under "Direct Capital Costs" denoted by footnote number1 in both tables of "Estimates of Total Capital Investment" for "Shared Facilities" and "Stand Alone" as submitted on December 11, 2009. Item (1) (b) "Auxiliaries/Balance of Plant" of both tables has footnote number 3. This footnote should be revised to read as follows: "Includes service air and sootblower air compressors, induced draft booster fan(s) and dampers, urea-to-ammonia conversion ~~flue gas reheat~~ equipment with natural gas-firing burners and fan(s), SCR bypass ducts and isolation dampers, interconnecting ductwork, equipment for active coal yard storage modifications, and catalyst standby heating auxiliary equipment costs as well as mechanical setting of this equipment". A revised version of the referenced document with the corrected footnotes is being submitted (see Enclosures).

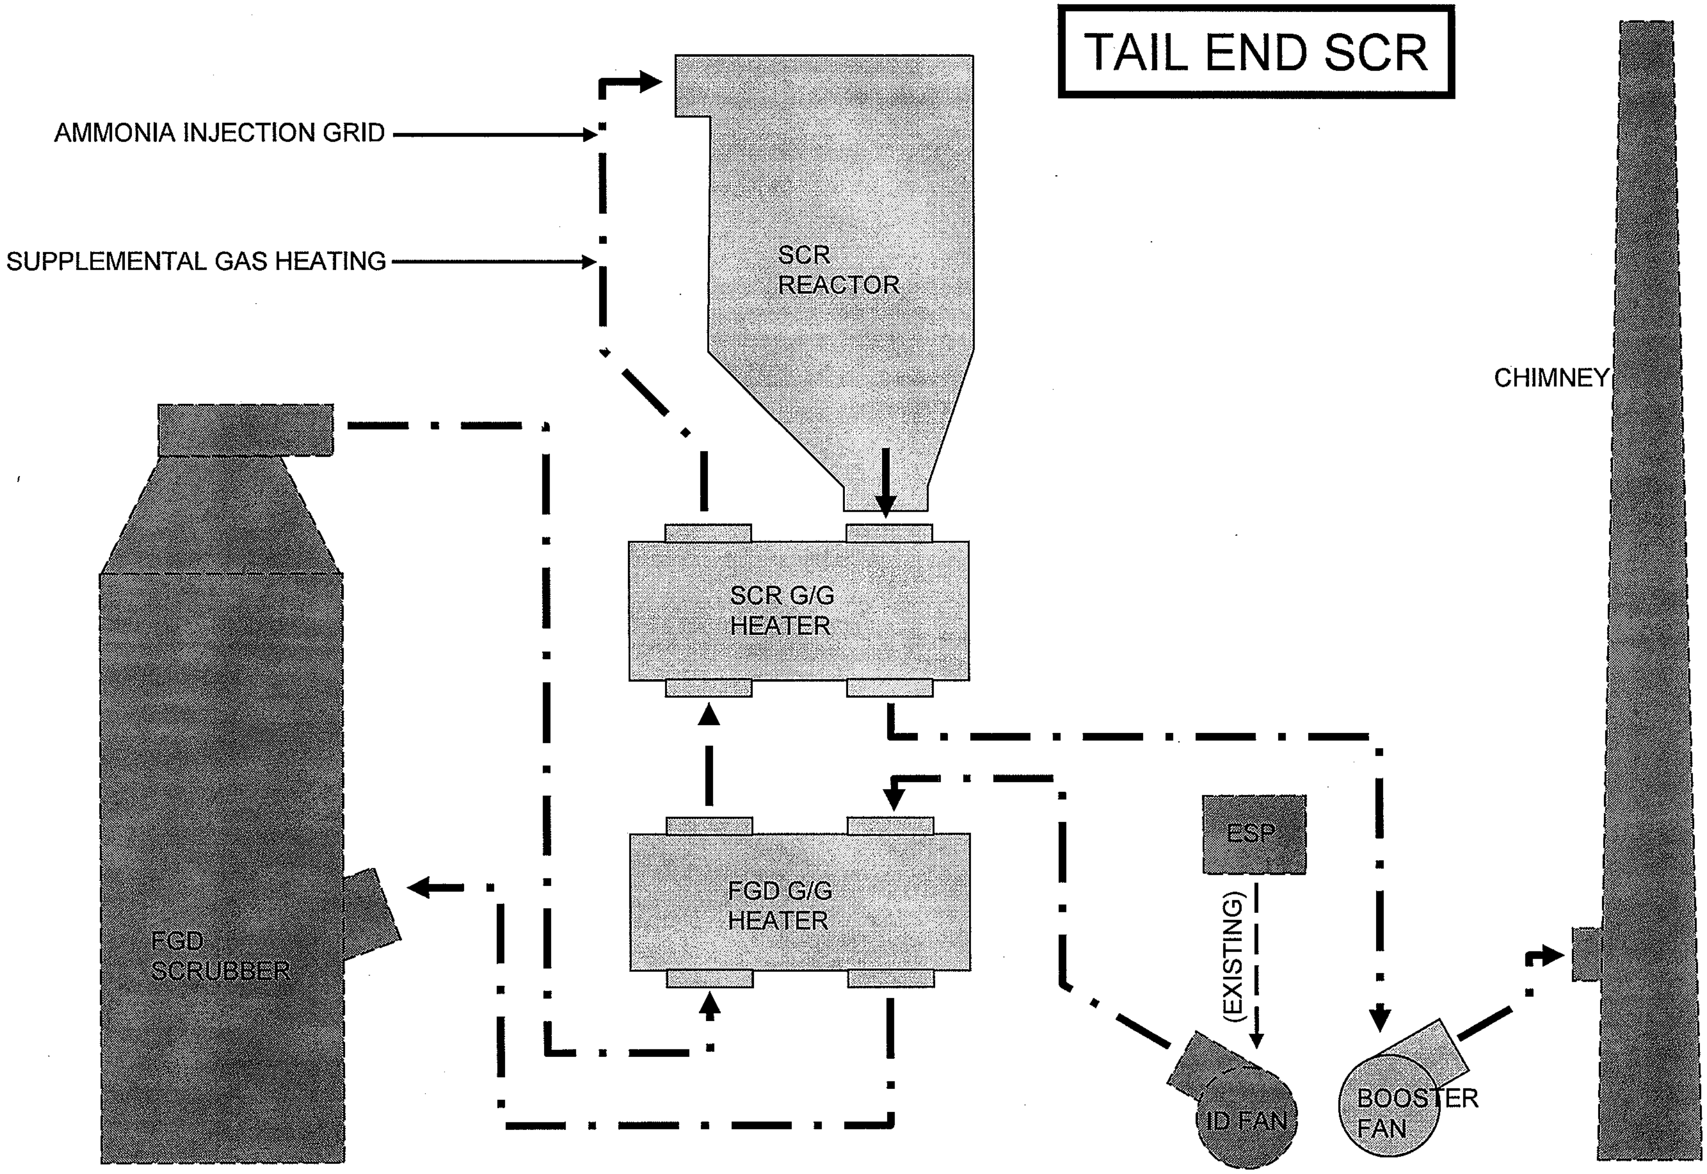
SKETCH SK – FD2

TAIL END SCR



ERRATA – MRYS Unit 2 Supplemental NOx BACT Analysis Study Report (November 2009)

Unit 2 Supplemental NOx BACT Analysis Study Report November 2009, page 4-23:

The second sentence of the paragraph should be revised to delete the words "per reactor":

> SCR catalyst replacements are additive to the general annual hypothetically-applied low-dust and tail end SCR equipment maintenance. Catalyst replacement costs are based on catalyst vendor quotation of volume of catalyst, estimated to be three layers initially (top, middle-upper and middle-lower) at 256 cubic meters per layer ~~per reactor~~ for two reactors in parallel. A fourth (bottom) layer at 342 cubic meters is expected to be required after initial operation of hypothetically-applied full-time tail end or low-dust SCR alternatives, as part of the catalyst replacement program. Catalyst replacement costs for the hypothetical application of SCR alternatives were estimated for the two different catalyst management scenarios described above.

GREAT RIVER
ENERGY℠

February 9, 2010

Lewis Dendy
North Dakota Department of Health
Division of Air Quality
918 East Divide Avenue, 2nd Floor
Bismarck, ND 58501-1947

Dear Lew,

Great River Energy (GRE) respectfully submits our response to questions raised by US EPA concerning ammonia in fly ash relevant to our Coal Creek Station (CCS). To address the issues raised by Amy Platt of US EPA in a November 30, 2009 email message to Tom Bachman of NDDH, GRE provides the following responses:

1. Response to Amy Platt's email
2. Fly Ash usage and properties

Response to Amy Platt's email

Amy Platt's email references Dynegy's Baldwin Energy Complex and Progress Energy's Roxboro Generating Station as facilities that have post combustion NOx control and market their fly ash. Both facilities have Selective Catalytic Reduction (SCR) installed, not Selective Non-Catalytic Reduction (SNCR) technology. It is typical for SCR technology to operate with lower ammonia injection and slippage rates than comparable SNCR technology. With SCR technology additional mixing and chemical reaction assistance is introduced in the catalyst packing resulting in reduction in NOx emissions. SNCR technologies require additional ammonia injection to ensure contact with the NO_X molecules in the flue gas, as they do not benefit from additional mixing or the benefit of enhanced chemical reactions provided by the catalyst packing. Headwaters Resources, GRE's fly ash marketer, on average sees ammonia content in ash from 200-600 ppm for SNCR units and from 50-400 ppm for SCR units. *See Attachment 3 section.*

Dynegy's 1,800 MW Baldwin Energy Complex has 3 units burning Powder River Basin (PRB) coal. Two of the units have SCR installed, the third unit has no post-combustion NO_X control technology. Headwaters Resources, GRE's fly ash marketer, is also the ash marketer for the Baldwin Energy Complex. Headwaters only markets ash from the one pulverized coal unit that does not have either SCR or SNCR installed and therefore the ash sold does not contain ammonia. Please see attached letter from Herbert Moeckel of Headwaters Resources. *In Attachments 1 section.*

Currently there are no installations of SCR or SNCR burning North Dakota Fort Union lignite. As GRE does not have any data or experience with ammoniated ash we have asked our fly ash marketer, Headwaters Resources, to respond to Amy Platt's chemistry statement that alkaline ashes experience lower uptake of ammonia. Headwaters has extensive experience with ammoniated ash and they have observed higher ammonia odor emissions from a plant (East Lake Plant, OH) producing a higher alkaline ash. The mechanism for this higher evolution of ammonia has not been identified and is currently being investigated. *See email thread of December 29, 2009-in Attachment 2 section.* Without empirical evidence on uptake of ammonia on ash from ND lignite GRE cannot assume ammonia slippage rates or retention rates on fly ash. We have also presented the question about expected ammonia in ash for lignite units to Tony Facchiano, Sr. Program Manager at the Electric Power Research Institute (EPRI) and although they have done work for other types of coal they have not conducted research with ND lignite and would not be able to correlate the ammonia in ash with ammonia slip at this time.

As there are no data from Fort Union lignite on SNCR ammonia retention in ash we have provided testimony from GRE customers. As noted by our customers, ammonia-impregnated ash would have an economic impact not only on GRE but also to our marketers who sell the ash. *See enclosures from Lafarge and GCC of America in the Attachment 1 section.*

Fly Ash

Fly ash for use in concrete is classified in 3 classes: Class N – raw or calcined natural pozzolans that comply with ASTM C618-08; Class F - typically produced from burning anthracite or bituminous coal, but lignite also; Class C – typically produced from burning lignite's, but may also be produced from burning anthracite or bituminous coal as long as the total calcium contents are higher than 10% and the ash has some cementitious properties. CCS ash is classified as a Class F ash. Introduction of ammonia will not affect the class of our fly ash but will decrease the desirability and thus the marketability of our ash if the customer perceives a health risk or is able to procure the same material without the objectionable qualities.

The original investments made in the infrastructure for the marketing of fly ash was predicated on the fact that CCS is a mine mouth plant with a consistent coal source which is producing a high quality fly ash which is very desirable in the concrete market. The introduction of undesirable characteristics into the fly ash, such as an odor or inhalation risk, will force our concrete customers to pursue alternate marketers for their feedstock. *See testimonials from Headwaters Resouces, Lafarge, and GCC in the Attachments 1 section.*

Please contact me at 763-445-5208 regarding any questions or comments.

Sincerely,

GREAT RIVER ENERGY

Adding Value to Energy

January 28, 2010

Mr. Al Christianson
Manager, North Dakota Business
Development & Governmental Affairs
1611 East Century Avenue
Suite 200
Bismarck, ND 58503

Dear Mr. Christianson:

I am writing in regards to the Dynegy Midwest Generation – Baldwin Energy Complex located in Baldwin, Illinois. Headwaters Resources is the marketing company for all five Dynegy Midwest Generation plants located in Illinois.

The Baldwin Energy Complex is composed of three – 600 MW units, totaling 1800 MW. Units 1 and 2 are cyclone fired boilers and Unit 3 is a pulverized coal boiler, all three units are burning PRB coal. Units 1 and 2 are equipped / operating with an SCR and Unit 3 has neither a SCR or SNCR installed.

Headwaters Resources has mainly marketed the cyclone boiler fly ash produced from Units 1 and 2 into the cement industry as a raw feed ingredient since 1998. Since 2000, we were able to market approximately 17,000 tons of this material into "flowable fill" on a few mine subsidence projects in the East St. Louis, Illinois area. We have performed ammonia testing on the fly ash produced from Unit 1 and 2 utilizing the Headwaters SOP using dragger tubes. This material fluctuates between 35 and 125 ppm ammonia in the fly ash. The ammonia odor was noticeable when used on the flowable fill mixes which contained high volumes of fly ash per yard. The ammonia odor did not have an impact on our sales agreement with Buzzi Unicem, since they were using the material as a raw feed ingredient in the production of cement. Starting in July 2009 new mercury regulation forced the power stations in Illinois to use activated carbon injection to reduce mercury emissions. Units 1 and 2 did begin activated carbon injection in July 2009 at which time the material was no longer allowed to be used in the production of cement. At this time 100% of the fly ash material produced from these units is being disposed of in an on site impoundment. Dynegy is constructing SDA scrubbers which should be complete by 2013, at which time the injection point of the activated carbon will be moved allowing the use of the fly ash material in cement production. The fly ash produced from these two units is not suitable for use in concrete.

Unit 3 at the Baldwin Energy Complex was granted a temporary variance which did not force this unit to inject activated carbon until the SDA / Bag house is operational at the end of 2010. Headwaters Resources has marketed the ASTM C618 Class C fly ash produced from unit 3 into ready mix concrete, concrete paving, and soil stabilization since 1998.

Please feel free to contact me at 612-963-7093 regarding any questions or comments.

Al,

We would like to take this opportunity to express concern about GRE's potential injection of ammonia into the flue gas during coal burning operations as an effort to reduce NOx emissions. As a wholesale marketer and end-user of your fly ash from the Coal Creek facility in North Dakota, our concern surrounds the impact this process will have on the fly ash when used in concrete.

The ammonia in fly ash is not present as ammonia gas. Rather, it is in the fly ash as ammonium sulfate. Once in the high alkaline environment of concrete the ammonia is released. This becomes a problem because of the odor, especially in enclosed spaces such as residential basements. The smell of ammonia is objectionable and would potentially impact external fly ash sales for GCC of America and internal use in the concrete operations owned by GCC Ready Mix..

Our professional experience with this situation in the past had been limited to the senses, i.e. eye and nose irritation and unpleasant odor. The corrective action taken was at the expense of the concrete producer, causing those customers to do business elsewhere.

We value our relationship with your company and prefer to use your product because of its quality and performance. Please do not allow these attributes to be compromised. If you should have any questions, or if we may be of further assistance, please contact either of us our Denver offices at (303) 739-5900.

Sincerely,

Adding Value to Energy™

January 11, 2010

Mr. Al Christianson
Manager, North Dakota Business
Development & Governmental Affairs
1611 East Century Avenue
Suite 200
Bismarck, ND 58503

Dear Mr. Christianson:

The Eastlake power plant in Eastlake, Ohio had a SNCR installed over 2 years ago. Prior to the installation the plant produced a high quality F-ash which was sold out every year during the construction season. The ammonia level was between 200-400 PPM after the installation which was when the problems started. Anything over 100 PPM seemed to be a noticeable at this plant.

We started shipping the material when it was in the 100-200 PPM range and the customers, batch plants and several contractors started calling with complaints especially in confined spaces such as buildings and basements. In one case a Ready Mix plant employee stuck his head in the back of the truck to add air entraining agent and it burned his eyes. He spent the night in the emergency room getting his eyes washed out not knowing it was the fly ash causing the ammonia smell.

We quit shipping anything over 100 PPM and business started dropping off; contractors did not want fly ash in their mixes. Since you're only checking a small amount of ammonia in the load it would test for less than 100 PPM but in some cases the Ready Mix producer still had problems which indicated the entire load was not less than 100 PPM. We shut down a block plant and the customer made us take the fly ash out of his silo and he quit buying fly ash from us.

Subject: Ammonia Injection in Fly Ash

Lafarge has used fly ash from power sources where SNCR ammonia injection units have been installed. We have found that when the ammonia levels exceed 40 parts per million in the fly ash that the consumer notices the ammonia and find it to be objectionable.

Lafarge is concerned that if ammonia injection units are installed at Great River Energy's Coal Creek Station it may cause the fly ash that is produced to be unmarketable. Lafarge currently purchases a large percentage of the fly ash that is produced at this station and would be placed at an economic disadvantage if we were no longer able to market this high quality ash to our ready mix customers.

This would cause our customers in turn to be at an economic disadvantage if they had to use fly ash from another source that is further away or use slag cement that perhaps would be more expensive than Coal Creek ash.

Subject: FW: Where are we at?

Al: Attached is Bruce's response to your latest inquiry. It appears that we are still waiting on Mr. O'Conner (EPRI) to review our data on Sammis and East Lake ash. The attached brochure from STI may be helpful in the comparison of SNCRs and SCRs in regard to ammonia being introduced into the ash. I don't know if this is sufficient for your needs. If not, I suggest that we (Diane, you, and I) get on a conference call with Bruce to discuss what else we may be able to provide. Just let me know. Thanks.

Subject: RE: Where are we at?

Jerry,

There was no official document generated by EPRI to circulate on this issue. The curious finding that the more alkaline ashes had higher ammonia odor emissions was reported to EPRI but the reason for the finding was never identified. Dave O'Connor at EPRI will review our data showing the data on Sammis and East Lake comparisons.
The data from our East Lake plant with SNCR and higher alkaline ash should be available shortly to compare with the much lower levels of ammonia from an SNCR associated with low alkalinity ash at Sammis.

STI found it necessary to develop an ammonia removal/treatment system in addition to the carbon removal system they operate at several locations. I do not know if the Roxboro plant uses this system but I would point out that with the storage dome at Coal Creek, the ammonia levels that could accumulate would be extremely hazardous. A little know fact is that ammonia is an explosive gas at certain levels when it accumulates with air present. See attached STI brochure on ammonia removal. In that brochure they support the fact that SNCR units will introduce much more ammonia to the ash than SCRs but both can prevent ash from being used in the market.

Where is Headwaters at on the SNCR justification documentation? I saw the waiting for EPRI response but when do they plan on having something to us?

Attachment 3: Headwaters information on SCR vs. SNCR

Ammonia Contamination Levels

Air Pollution Control Process	NH_3 "Slip" ppm$_v$	NH_3 in Ash mg/kg
SCR	2 to 10	50 to 400
SNCR	5 to 20	200 to 600
SO_3 Control	10 to 20	300 to 600
ESP Conditioning	20 to 30	600 to 1200

Actual ammonia concentrations will depend on ammonia injection rates, coal type, sulfur content, and other operating parameters.

Environmental Groups

Comment I: The Clean Air Act and Federal Regulations Require NDDH to Abate Visibility Improvement.

A) The BART limits fail to reflect the best degree of continuous emission reduction achievable.

Response: The determination of BART is based on five factors: 1) the cost of compliance; 2) the time necessary for compliance; 3) the energy and non-air quality environmental impacts; 4) the remaining useful life of the source; and 5) the degree of visibility improvement. The NDDH considered all five factors in determining BART. BART is not necessarily the lowest possible emission rate or the emission rate (or technology) that achieves the maximum visibility improvement. All of the five factors must be considered. The NDDH is free to determine the weight and significance assigned to each factor (40 CFR 50, Appendix Y, Section IV.D Step 5). A response to specific comments on the BART analyses follows.

B) North Dakota should actively encourage other states and Canada to reduce emissions that impair visibility.

Response: The NDDH has consulted with other states as part of WRAP and the Northern Class I Areas workgroup. Significant emissions reductions will come from sources in each state involved in these groups. Negotiations with a foreign country are reserved to the U.S. Government. The NDDH is hopeful that the U.S. EPA and the U.S. State Department will pursue reductions at Canadian sources; however, the State of North Dakota has no control over these agencies.

Minnesota asked for additional reductions from EGUs in North Dakota. However, Minnesota's request was not based on the four factors that must be evaluated for reasonable progress. The NDDH suggested that Minnesota consider the fourth factor (cost of compliance) in their analysis, especially dollar per deciview improvement.

Comment II: NDDH's Draft BART Determinations are Flawed

II.A. NDDH purported to do a case-by-case evaluation of BART, it appears the case-by-case analysis were simply written to support the presumptive levels.

Response: Each EGU was evaluated considering the five factors. Since the original BART submittals, the NDDH has required 95% removal at Leland Olds Unit 1 and M.R. Young Unit 2 compared to the 90% removal proposed by the companies. At Stanton Station, GRE originally proposed sorbent injection. The NDDH has required a dry scrubber. The NDDH's evaluation of BART indicates these sources may exceed the 0.15 lb/10^6 Btu presumptive limit when higher sulfur coal is encountered. Instead of establishing a higher lb/10^6 Btu limit, the NDDH maintained the 0.15 lb/10^6 Btu presumptive limit but gave the sources the option of complying with the 95% reduction requirement.

None of these sources are subject to the BART Guidelines in 40 CFR 50, Appendix Y for SO_2. All the plants except Coal Creek Station have a nameplate capacity less than 750 MWe. Coal Creek Station is not subject to the BART Guidelines for SO_2 since its existing scrubbers are achieving greater than 50% removal efficiency. The NDDH considered the five statutory factors and determined BART appropriately.

II.A.I: NDDH Cannot Take into Account Projected Worst-Case Sulfur Content of Coal in Setting BART Limits.

Response: The BART Guideline states "The baseline emissions rate should represent a realistic depiction of **anticipated** [emphasis added] annual emissions for the source." This statement clearly indicates future conditions should be utilized if it is different from historic conditions. EPA has allowed the use of the last 5 or 10 years for establishing the baseline (EPA – Additional Regional Haze Questions, August 3, 2006; Question 7). Because North Dakota lignite is extremely variable, using the highest 24-months out of the last 5 or 10 years may not give a realistic depiction of future conditions. Therefore, using the highest annual average sulfur content from a future period is consistent with the BART Guideline and EPA guidance.

In the case of Leland Olds, coal sulfur data was provided based on core sampling from the Freedom Mine (See Appendix B.2). The data shows an annual average sulfur content of 1.13% for 2019 and 1.12% for 2020. Since these are annual averages, they do not represent the maximum sulfur content that may be encountered during a given 30-day rolling average basis. For Coal Creek, the coal sulfur content selected was based on the 98th percentile of the coal sulfur data provided by GRE. The NDDH believes this is realistic for future emissions from Coal Creek.

For Milton R. Young Station, the average sulfur content from various core samples was used (see Table C.11, 4/18/07 Response to Comments). The maximum sulfur content is 5.5%.

For Unit 1 at the M.R. Young Station, the commenter is confusing the 2000-2004 average emission rate with the baseline emission rate. As noted earlier, the baseline emission rate, as suggested by EPA, is based on the maximum two years of emissions out of the last five years, not the entire five year period. Obviously, the five year average will be less than the maximum two year period. The commenter states that if actual emissions were reduced by the projected amount, Unit 1 would be emitting negative amounts of $SO_{2,}$ which is an impossibility. The commenter's statement is based on the 2000-2004 average SO_2 emission rate. Use of a five year average is contrary to the BART guideline and other guidance which indicates a two year average should be used. Had the Department used the 2000-2004 average emission rate as the baseline, an emissions reduction of 95% would have indicated emissions (after the wet scrubber) of 1007 tpy, not a negative emission rate.

For Stanton, the maximum uncontrolled emission rates expected are 2.4 $lb/10^6$ for lignite and 1.60 $lb/10^6$ Btu for subbitimunous coal (See Appendix E of GRE's analysis). In the NDDH BART analysis, 1.81 $lb/10^6$ Btu was used for lignite and 1.2 $lb/10^6$ Btu for subbituminous coal.

It is obvious the NDDH BART analysis did not use the maximum sulfur coal. The NDDH made a determination that the lower values would realistically depict future emissions.

II.A.2: The Proposed BART Limits Fail to Reflect the Degree of SO_2 Reduction Achievable with the BEST SO_2 Controls.

The commenter claims that 99% removal efficiency can be achieved using the Chiyoda CT-121 FGD or the Mitsubishi double contact flow scrubber.

<u>Response</u>: Regarding the Mitsubishi DCFS, literature by ADVATECH (copy attached to this response) for this scrubber indicates it can achieve very high sulfur removal efficiencies on high sulfur coal. However, tested performance on installed FGD systems indicate down to 90% removal efficiency for sulfur inlet concentrations of 1000 ppm or less. For North Dakota lignite, the inlet concentration is generally below 1000 ppm. The commenter also references two technical documents and a single sheet of information with no explanation of the source. These documents indicate high efficiencies at high inlet SO_2 concentrations (>1000 ppm), but low efficiencies (<95%) at most of the sources tested where the inlet sulfur concentration was less than 1000 ppm. The Department has proposed a wet scrubber that will achieve at least 95% removal under all inlet loadings. The NDDH is not convinced that this technology will provide any additional SO_2 removal.

The Chiyoda CT-121 FGS is a bubbling jet reactor which the commenters claim has achieved 99% SO_2 removal in Japan on coal fired boilers. The commenters provided several technical documents in an attempt to support their claim. The Black and Veatch brochure provides a list of installed and proposed facilities. The installed facilities have SO_2 removal efficiencies between 70-99%. However, for most of the facilities with lower inlet SO_2 concentrations, the removal efficiency is below 95%. This shows a wide range of efficiencies with little useful data.

The technical paper by Yasuhiko Shimoganci et.al. indicates an SO_2 removal efficiency of 99% at the Shinko-Kobe Power Plant in Japan. This paper provides no data on averaging times, the variability of the coal burned, or permittee emissions limits. It is also the NDDH's understanding that this plant has experienced operational problems with scaling of the FGD's sulfur gas fan which requires two days of maintenance every 2-3 months. The NDDH believes that it would be unreasonable to require this technology given the high outage time.

The commenters pointed out several facilities where this technology has been demonstrated or is to be deployed. This entire comment is nearly identical to one submitted on the Desert Rock BACT analysis. EPA investigated these claims and still rejected this technology as BACT (see attachments).

The commenter also refers to a "LADCO and MRPO" presentation that indicated the technologies could achieve 99.5% control for $1,240 to $2,875 per ton of SO_2 removal. Apparently, these figures were based on 2.5% sulfur which is twice as high as that proposed for any of the North Dakota BART sources. More detailed information would be required from the commenter to assess the cost for this lower sulfur coal.

As indicated earlier, this comment is nearly identical to one submitted for the Desert Rock Power Plant BACT determination. EPA's response to this comment for Desert Rock is attached to this response. The NDDH agrees with EPA's BACT determination which rejected this technology. The NDDH does not consider the Chiyoda CT-121 scrubber or the Mitsubishi DCFS to be BART.

II.A.4 a, b, c: The Proposed SO_2 BART Limits Should be Expressed Multiple Ways.

The commenter indicates that 98-99% removal efficiency should be required based on the technology discussed in Comment II.A.2. The NDDH believes this removal efficiency is not feasible on a continuous basis for lower sulfur lignite (<1.5% sulfur). New wet scrubbers generally achieve SO_2 removal efficiencies of 95% (Institute of Clean Air Companies, 2008; Federal Register Vol. 70, No. 28, P.9715). EPA (Air Pollution Control Technology Fact Sheet; EPA-451/F-03-034) indicates "Chlorine content improves SO_2 removal…" North Dakota lignite has some of the lowest chlorine levels of all the U.S. coals. Based on the low chlorine content and lower sulfur content, the NDDH believes that 95% is a reasonable removal efficiency for a scrubber to meet on a continuous long-term basis which includes startups, shutdowns and malfunctions.

The commenter also states the proposed BART limit of 0.15 lb/10^6 Btu should be lowered based on <u>current</u> coal sulfur content. The commenter does not acknowledge that higher sulfur coal will be burned in the future. The future coal sulfur content is based on actual core samples from future mining areas. As explained in the response to Comment II.A.1, the baseline for determining the BART limit is based on the <u>anticipated</u> emissions that are expected to occur. The NDDH considers the core samples of future mined coal to be strong evidence of anticipated emissions. Based on 95% removal, the M.R. Young plant would have an SO_2 emission rate of 0.60 lb/10^6 Btu when the maximum sulfur coal of 5.6% is burned. Using one standard deviation from the average sulfur content would yield a controlled emission rate of 0.17 lb/10^6 Btu.

At the Leland Olds Station, a maximum 30-day rolling average of 0.19 lb/10^6 Btu would be expected based on an <u>annual average</u> sulfur content of 1.13% and 95% reduction. At Coal Creek, a 30-day rolling average SO_2 emission rate of 0.18 lb/10^6 Btu would be expected based on an annual average sulfur content of 1.1%. The NDDH stands by its decision to limit emissions to 0.15 lb/10^6 Btu.

The commenter also wants a mass per unit of time emission limit included in the BART Permit to Construct. The NDDH contacted EPA Region 8 earlier in the BART process regarding this issue. In a November 21, 2005 email response from Laurel Dygowski of EPA Region 8, it was stated "We think a 24-hour limit is unnecessary and may not be of much value." Given the small amount of emissions coming from these sources after controls, a mass per unit of time emission rate will be easily calculated with very good accuracy.

The NDDH stands by its decision not to include a mass per unit of time emission rate.

II.A.4.d: Comments Regarding the Stanton Station Unit 1 SO_2 Emission Limits

The commenter states that "there is no valid justification for NDDH to increase the derived emission rate reflective of 90% control by 33%". The commenter refers to the 33% adjustment factor used by the Department to adjust from an annual average emission rate to a 30-day rolling average emission rate.

It is common practice to establish higher short-term limits to allow for short-term emissions variability inherent to facility operations. The EPA RACT/BACT/LAER Clearinghouse contains numerous examples of short-term BACT limits which are higher than longer-term BACT limits. For example, a permit issued to Omaha Public Power District (RBLC ID NE-0031) on March 9, 2005 establishes a 3-hour average SO_2 BACT emission limit of 0.48 lb/MMBtu compared to the 24-hour SO_2 BACT limit of 0.163 lb/MMBtu and a 30-day rolling average SO_2 BACT limit of 0.095 lb/MMBtu. A permit issued to Wellington Development / Greene Energy (RBLC ID PA-0248) on July 8, 2005 establishes a 3-hour average SO_2 BACT limit of 0.234 lb/MMBtu and a 30-day rolling average SO_2 BACT limit of 0.156 lb/MMBtu. A permit issued to River Hill Power Company (RBLC ID PA-0249) on July 21, 2005 establishes a 24-hour average SO_2 BACT limit of 0.274 lb/MMBtu and a 30-day rolling average SO_2 BACT limit of 0.20 lb/MMBtu. Two examples where annual and 30-day rolling average BACT limits were established include permits issued to Associated Electric Cooperative (RBLC ID MO-0077) and Western Farmers Electric Cooperative (RBLC ID OK-0118). The permit issued on February 22, 2008 to Associated Electric Cooperative establishes a 30-day rolling average NO_x limit of 0.065 lb/MMBtu and an annual average NO_x limit of 0.05 lb/MMBtu. The permit issued on February 9, 2007 to Western Farmers Electric Cooperative establishes a 30-day rolling average NO_x limit of 0.07 lb/MMBtu and an annual average NO_x limit of 0.05 lb/MMBtu. In addition, a permit issued by EPA on July 31, 2008 for the Desert Rock facility establishes a 30-day rolling average NO_x limit of 0.05 lb/MMBtu and an annual average NO_x limit of 0.0385 lb/MMBtu. Clearly, it is common practice to establish short-term BACT limits which are higher than longer-term BACT limits.

The Department has reliable data based upon actual facilities operating in North Dakota to support the use of the 33% adjustment factor. In addition, adjustment factors (to adjust from an annual average limit to a 30-day rolling average limit) calculated from Associated Electric Cooperative, Western Farmers Electric Cooperative and Desert Rock limits are approximately 30%, 40% and 30%, respectively. These adjustment factors are very close to the adjustment factor of 33% used by the Department. Since the Department has reliable data to support the use of the 33% adjustment factor and no data has been submitted indicating that the factor is not appropriate, the Department maintains the position that the 33% adjustment factor is appropriate.

The commenter states that spray dryers can achieve greater than 90% SO_2 removal and references permits issued for the Newmont Nevada TS, White Pine, Toquop Energy and Dry Fork facilities.

The Newmont Nevada TS power plant construction permit requires a 95% control efficiency when combusting coal with a sulfur content equal to or greater than 0.45% and a 91% control efficiency when combusting coal with a sulfur less than 0.45%. Based upon this permit, it is possible for the facility to operate with lower sulfur coal, maintain a control efficiency of 91% and meet the requirements of the permit. The Department does not consider a 91% control efficiency to be significantly different than a 90% control efficiency and the commenter provides no data indicating that a control efficiency greater than the 91% requirement has been routinely attained at the Newmont Nevada facility. The Department conducted the BART analysis for Stanton Station #1 when combusting PRB coal assuming an uncontrolled emission rate of 1.2 lb/MM Btu (on an annual average basis) and a control efficiency of 90%. If slightly higher sulfur coal is burned at Stanton Station #1, then the facility will need to attain a slightly higher removal efficiency than 90% to maintain compliance with the emission limit. Although a slightly higher control efficiency may be attainable on a short-term basis, the Department maintains the position that a standard spray dryer is routinely capable of a 90% SO_2 control efficiency, especially when periods of startup, shutdown and malfunction are included. The Department considered other control technologies (wet scrubber, circulating dry scrubber) with higher control efficiencies than 90% in the BART analysis and eliminated these technologies based upon cost and other environmental considerations.

The commenter references a "draft Toquop permit" as exhibit 22. However, as submitted, both exhibit 21 and 22 are the Desert Rock permit, so it appears the Toquop permit was excluded from the exhibits. The Department has reviewed the draft permit for the Toquop Energy, LLC facility on the Nevada Division of Environmental Protection web site and has found that the control technology proposed for the Toquop facility is a wet scrubber, not a spray dryer. Since the Toquop facility will be employing a wet scrubber, the draft permit for the facility does not support the commenter's position regarding the control efficiency of a spray dryer.

The commenter indicates that the White Pine power plant has not been constructed and is "indefinitely postponed", so this provides no evidence that a spray dryer can routinely attain SO_2 control efficiencies greater than 90%.

The commenter references the Dry Fork Station as evidence that a spray dryer can attain greater than 90% SO_2 control efficiency. However, the control technology to be used at the Dry Fork Station is a circulating dry scrubber, not a spray dryer. The Department did consider a circulating dry scrubber (at 93% SO_2 control efficiency) in the BART analysis for Stanton Station #1 and determined that the incremental cost of a circulating dry scrubber (compared to a spray dryer) is excessive.

The commenter argues that spray dryers can achieve greater than 90% SO_2 removal and presented four facilities (Toquop Energy, Dry Fork, White Pine and Newmont Nevada) to support this argument. The Toquop Energy and Dry Fork facilities are not proposing to use a spray dryer to control SO_2 emissions. The White Pine facility does not appear to have been issued a permit. The only facility which is employing a spray dryer and which has operated is the Newmont Nevada facility. However, as indicated above, the Department is not aware of any data from this facility demonstrating that a standard spray dryer can routinely attain SO_2 control efficiencies greater than 90%.

Based upon the above, the Department maintains the position that a standard spray dryer can be expected to routinely attain an SO_2 control efficiency of 90%.

The commenter states that the Department eliminated a wet scrubber from consideration as BART based only on the small amount of visibility improvement. The commenter argues that, since the cost of a wet scrubber is not prohibitive, the Department must require the use of a wet scrubber as BART at Stanton Station #1.

The BART determination for Stanton Station #1 clearly states that the Department chose a spray dryer as BART as opposed to a wet scrubber based upon both the additional environmental impacts and the small visibility improvement of a wet scrubber as compared to a spray dryer. The additional environmental impacts of a wet scrubber were outlined in the BART determination as follows:

- A wet scrubber is estimated by GRE to use as much as 20% more water or approximately 15 million gallons per year of additional water.
- It is assumed that a wet scrubber system will require additional on-site ponding. GRE has identified two potential areas on site that could be used for the additional ponding. The areas include the existing ash pile, which would have to be excavated and moved, or the abandoned ash disposal area adjacent to the river, which reportedly has geotechnical deficiencies.
- Dry scrubbers are purported to achieve a higher mercury control efficiency on lignite and PRB as compared to a wet scrubber. In addition, future mercury control requirements could result in high concentrations of mercury in the ponds and prove problematic to discharge.

Considering the additional environmental impacts and the fact that a wet scrubber will result in a small visibility improvement beyond the control achieved by a spray dryer, the Department maintains the position that BART for SO_2 at Stanton Station #1 should be established as a spray dryer with a fabric filter.

The commenter states that a wet scrubber can attain SO_2 removal efficiencies of 98-99%. See responses to comments for Sections II.A.4.a, b and c.

The commenter states that the Department should establish both a numerical emission limit and a minimum control efficiency for SO_2. The BART guidelines list the presumptive levels in units of lb/million Btu or a percent reduction. Given that the presumptive levels are listed in units of lb/million Btu or a percent reduction, the Department does not believe it is appropriate to establish emission limits on a lb/million Btu and percent reduction basis.

II.A.5: There Are Other Benefits to NDDH Requiring Stringent SO_2 BART Limits That NDDH Must Take Into Account.

The commenter indicated that the NDDH should control SO_2 to low levels to facilitate the capture of CO_2. There are currently no regulations that require CO_2 capture. There are only a few technologies that are in various stages of development from bench scale to testing at full scale. The NDDH cannot consider what may happen in the future regarding CO_2 capture. A cap and trade program may make purchasing CO_2 credits (allowances) more economically feasible than capture. New technologies may be developed which do not require low SO_2 concentrations.

The NDDH believes CO_2 capture is currently only in its infancy and future regulatory requirements are too uncertain at this time to be considered in the current BART determinations.

The commenter also indicates that $PM_{2.5}$ concentrations will also be lowered with lower SO_2 emissions and this should be considered in the BART determination. The commenter's statement is true that lower SO_2 emissions will probably lead to lower $PM_{2.5}$ concentrations. The entire state of North Dakota is in compliance with current NAAQS for $PM_{2.5}$. BART requirements will reduce SO_2 emissions by nearly 100,000 tons per year. This should reduce $PM_{2.5}$ concentrations significantly in affected areas. The small emissions reductions going from 95% SO_2 reductions to 98-99% reduction will have little effect on ambient $PM_{2.5}$ concentrations due to dispersion of the plumes. The NDDH considers this issue as insignificant in the BART determination process.

II.B.1: High Dust SCR (HDSCR) is Technically Feasible.

The commenter claims that high dust SCR is technically feasible for North Dakota lignite. The commenter expressed comments about several issues the NDDH discussed in the technical feasibility analysis. These include: 1) The variability of fuel composition; 2) Results for the Coyote Pilot testing; 3) Sodium in the ash; 4) Temperature variations, 5) Catalyst erosion and; 6) the Lack of vendor guarantees.

<u>Response</u>: The BART Guideline states "Where you conclude that a control option identified in Step 1 is technically infeasible, you should demonstrate that the option is either commercially unavailable, or that specific circumstances preclude its application to a particular emissions unit. Generally, such a demonstration involves an evaluation of the characteristics of the pollutant-bearing gas stream and the capabilities of the technology. Alternatively, a demonstration of technical infeasibility may involve a showing that there are irresolvable technical difficulties with applying the control to the source (e.g. size of the unit, location of the proposed site, operating problems related to specific circumstances of the source, space constraints, reliability, and adverse side effects on the rest of the facility)." The commenter did not supply any analyses of the flue gas from North Dakota lignite combustion to demonstrate that HDSCR is technically feasible. The commenter did address sodium in the flue gas by stating "At least one of the catalyst vender noted that sodium is not a poison to a catalyst at SCR operating temperatures." The commenter went on to say that proper operation will prevent catalyst deactivation and that if any condensation occurs, it can be mitigated by washing. The NDDH has concluded that moisture, or condensation, is not necessary to poison the catalyst. Zheng et.al (2008) concluded that the submicron aerosols of soluble potassium and sodium are transported into the catalyst pores by diffusion (i.e. surface diffusion). Several pilot and full scale tests have found rapid deactivation of SCR catalyst from potassium and sodium aerosols from biomass combustion when the catalyst was at normal operating temperatures. Haldor Topsoe (Crespi et.a.) in their paper, *The Influence of Biomass Burning in the Design on an SCR Installation* states "Submicron aerosols adhere to the catalyst surface or diffuse into the macro pores. The aerosols cannot diffuse into the clusters as primary TiO_2 support particles, which appear as islands at the catalyst surface. However, the alkalis are very mobile and are readily transported by surface diffusion into the clusters and react with the active sites. The reaction is not reversible:" The NDDH agrees that condensation will greatly enhance catalyst deactivation; however, severe catalyst deactivation from Na and K aerosols does occur at biomass boilers without condensation of moisture occurring.

Catalyst washing may help regenerate a catalyst that has been coated or the pores plugged. However, as Haldor Topsoe notes, when soluble Na or K reacts with the active sites, the reaction cannot be reversed by washing.

The commenter specifically addressed a) the variability of fuel composition, b) the Coyote Pilot testing, c) sodium, d) temperature variations, e) catalyst erosion, and f) lack of vendor guarantees.

a) Variability – The commenter indicated that the variability of North Dakota lignite was not an issue and that it can be overcome by proper design.

<u>Response</u>: The analyses that were conducted for the technical feasibility determination used an average ash content and average sodium and potassium content of that ash. Data supplied by the companies indicates that the ash content can be twice as high as the average and the Na_2O content can be 3-4 times the average (see Minnkota's 4/18/07 response to comments). The analyses indicate that average coal constituents will rapidly deactivate an SCR catalyst. If the amount of sodium is increased by a factor of 6-8, even more rapid catalyst deactivation is expected. The commenter has provided no evidence indicating that coals used at power plants that have HDSCR have such a high variability in the catalyst poisoning agents.

b) Results of the Coyote Pilot Testing – The commenter dismissed the results of the Coyote testing indicating that any conclusions from the testing should be rejected.

<u>Response</u>: The NDDH made only one conclusion from the testing. That is, there is a difference between subbituminous coal and North Dakota lignite when it comes to the design and operation of an SCR system. The Coyote testing showed much more severe plugging problems than at the Baldwin Station. This indicates the design may require a different pitch and a much larger reactor. As Sargent and Lundy (PowerPoint Presentation 5/2007) has noted, "Some important unanswered questions pose significant risk for an SCR design engineer."

- An unknown catalyst deactivation rate will prevent:
  - Optimum selection of a catalyst design
  - Selection of an appropriate reactor size

S&L also indicated "there are attributes of this fuel in an SCR environment that are not well understood today and need more investigation to predict its performance." The NDDH has concluded that pilot scale testing would be required before HDSCR could be deemed technically feasible. The BART sources are not required to do that testing.

c) Sodium: The commenter believes sodium is not an issue for SCR deactivation unless condensed water is available in the SCR reactor.

<u>Response</u>: See Response to Comment II.B.1

d) Temperature Variations – The commenter claims that high temperature variations should not preclude HDSCR from being technically feasible.

Response: High temperatures entering an SCR catalyst can quickly deactivate a catalyst through sintering. In order to determine if this problem can be overcome, expensive and lengthy engineering analysis will be required. The BART Guideline states "Alternatively, a demonstration of technical infeasibility may involve a showing that there are unreasonable technical difficulties with applying the control to the source (e.g. size of the unit, location of the proposed site, operating problems related to specific circumstances of the source, space constraints, reliability and adverse side effects on the rest of the facility)." Until the engineering studies are completed, temperature swings must be a consideration in determining technical feasibility.

e) Catalyst Erosion – The commenter contends that ash erosion is not a concern that has been substantiated.

Response: Catalyst erosion is a significant concern. Ash from North Dakota lignite has different abrasive qualities from other coals. The experience from other coals may not be applicable to North Dakota lignite.

f) Lack of Vendor Guarantees – The commenter claims that both CERAM and Haldor Topsoe have stated that they would offer guarantees for HDSCR.

Response: The commenter is correct that CERAM and Haldor Topsoe initially indicated they would offer guarantees. However, Minnkota has approached these same two companies regarding a guarantee for LDSCR and TESCR which should be less susceptible to catalyst poisoning than HDSCR. Both companies have refused to offer a guarantee for LDSCR or TESCR without pilot testing first (see NO_x Best Available Control Technology Analysis Study – Supplemental Report, November 2009). If these companies will not offer a guarantee for LDSCR or TESCR, it is expected they would not offer one for HDSCR.

The NDDH stands by its determination that HDSCR is not technically feasible for North Dakota lignite at this time.

II.B.2: TESCR and LDSCR are Cost Effective

The commenter indicates both TESCR and LDSCR are cost effective. This comment is based on a few BACT determinations and the National Park Service's database of BART determinations (preliminary and final by the States) that have not been promulgated in an EPA approved SIP. BART determinations are not the same as BACT determinations. For BART determinations, the amount of visibility improvement must be considered. The Department's analysis of LDSCR and TESCR indicate cost effectiveness values above $3,581 per ton and incremental costs at $5,978/ton or greater. The comparison to the NPS database indicated that costs are as high or higher than anything approved for BART. In addition, the amount of visibility improvement is very low (≤ 0.02 deciviews on the most impaired days). The high cost and miniscule visibility improvement dictates that SCR is not BART.

The commenter also indicated there was a lack of transparency regarding the methodology for developing the costs estimates. The cost estimates were developed by engineering consultants who are experienced with SCR design and installation. The estimate provides as much detail as the EPA Air Pollution Control Cost Manual which is recommended by the BART Guideline. The NDDH believes the cost estimates are within the ± 30% accuracy of the Control Cost Manual. Given the very small visibility improvement, the costs are of less importance. The NDDH stands by the estimated costs.

II.B.3: Specific Comments on Each NO_x BART Analysis

A) Lelands Olds Unit 1 - The commenter believes LDSCR is cost effective.

Response: The cost effectiveness of LDSCR ranges from $7,849/ton to $11,313/ton with an incremental cost of $12,489/ton. This is 6-9 times more than the EPA estimated cost of the controls necessary to meet the BART presumptive limits for lignite fired dry bottom wall-fired units. The cost is nearly twice that of most recent BACT determinations for NO_x. The State of Wyoming recently rejected a lower NO_x emission rate (0.043 lb/10^6 Btu) for the Dry Fork plant based on a cost effectiveness of $1,751/ton and an incremental cost of $10,300/ton. The NDDH stands by its determination that LDSCR and TESCR are not cost effective for Leland Olds Unit 1. The NDDH has required Basin Electric to meet an NO_x emission limit that is below the presumptive BART limit.

B) Leland Olds Unit 2 – The commenter believes HDSCR is technically feasible and LDSCR was rejected based on erroneous cost criteria.

Response: Regarding HDSCR technical feasibility, see Response to Comment II.B.1.

The commenter has provided no technical analysis or evidence to show that the cost estimate is erroneous. The NDDH stands by the cost estimate for LDSCR and TESCR.

C) Coal Creek Units 1 and 2 – The commenter states that HDSCR was improperly rejected and the use of 80% control for SCR biased the cost effectiveness to the high side.

Response: Regarding HDSCR technical feasibility, see Response to Comment II.B.1.

The Department has reviewed the EPA Air Pollution Control Cost Manual which states "In practice, SCR systems operate at efficiencies in the range of 70% to 90%. EPA's Air Pollution Control Technology Fact sheet for the selective catalytic reduction (EPA-452F-03-032) states "SCR is capable of NO_x reduction efficiencies in the range of 70% to 90%." The Oregon DEQ hired Eastern Research Group, Inc. (ERG) to review the BART analysis for the PGE Boardman Plant. In their review, ERG stated "With regard to the performance of existing low NO_x burners (LNB) with overfire air (OFA) and SCR, reductions of 70 to more than 90 percent have been documented from recent installations; however, these are based on units that operate mainly during the ozone season and that have substantial opportunity for off-season maintenance and catalyst cleaning. The impact of existing LNB with OFA and SCR of the Boardman Plant under year-round operation would need to be considered in selecting a permit level." The NDDH believes the use of 80% is a reasonable choice for a source that must meet a BART emission limit on a long-term continuous basis. In the ANPR for the Four Corners Power Plant (Federal Register 8/28/09), EPA states "APS estimated that SCR could achieve NO_x control of approximately 90% or greater from the baseline emissions. For new facilities, 90% or greater reduction in NO_x from the SCR can be reasonably expected. See May 2009 White Paper on SCR from Institute of Clean Air Companies. For SCR retrofits on an existing coal-fired power plant, Arizona Department of Environmental Quality (ADEQ) determined that 75% control from SCR (following upstream reductions by LNB) was appropriate for the Coronado Generating Station in Arizona. Based on this data, EPA has determined that an 80% control efficiency for SCR alone, rather than the 90% control assumed by APS, is appropriate."

The Department believes 80% is a reasonable estimate that allows the source to comply with the expected emission limit on a continuous basis.

D) Stanton Station Unit 1 – The commenter believes HDSCR was rejected improperly and a cost effectiveness of $6,475/ton is reasonable.

Response: Regarding the technical feasibility of HDSCR, see Response to Comment II.B.1

Regarding cost effectiveness, see Response to Comment II.B.3(a). The estimated cost effectiveness of $6,475/ton when burning lignite is five times the amount EPA found was cost effective for the presumptive limits for wall-fired lignite units. In addition, the incremental cost when burning lignite is $10,032/ton. This unit will meet the presumptive BART limits for both lignite and subbituminous coal.

E) M.R. Young Station Units 1 and 2 – The commenter states that the NDDH has done no more than is required by law and rolled it into the BART analysis. The commenter also states that HDSCR was rejected erroneously and the cost effectiveness of LDSCR and TESCR are reasonable.

Response: Although the Consent Decree requires the level of emissions that are proposed for BART, the NDDH conducted a BART analysis in accordance with the Five Step BART process. After considering the five factors, SCR was rejected as BART.

Regarding the technical feasibility of HDSCR, see the Response to Comment II.B.1.

With respect to cost effectiveness, see the Response to Comment II.B.3.A. The cost effectiveness of LDSCR and TESCR is three to five times the cost EPA had estimated for cyclone boilers to meet the BART presumptive emission rate. The Department believes these costs are excessive in comparison to EPA's analysis and are very high when compared to recent BACT determinations. However, the NDDH also considered the amount of visibility improvement and the other three factors in making its BART determination. The amount of visibility improvement (≤0.02 deciviews on the most impaired days) when compared to the next most efficient technology is trivial. The NDDH stands by its BART determination.

Comment III: NDDH Has Failed to Include Other Emission Reduction Requirements as Part of Its Long-Term Strategy to Meet Reasonable Progress Requirements which must be Designed to Meet the Goal of Natural Visibility Conditions by 2064.

The commenter indicated the following:

A) BART sources should have been reevaluated under the reasonable progress section of the SIP.
B) North Dakota is not doing its fair share to reduce visibility improvement.
C) SO_2 controls that achieve 98-99% efficiency should have been considered.
D) Costs alone should not eliminate controls on sources under BART.
E) The SIP does not go far enough to ensure that natural visibility conditions are achieved by 2064.

Response:

A) EPA has published guidance for determining Reasonable Progress for regional haze – Guidance for Setting Reasonable Progress Goals Under the Regional Haze Program, June 1, 2007. This document states "Also, as noted in Section 4.2, it is not necessary for you to reassess the reasonable progress factors for sources subject to BART for which you have already completed a BART analysis." Section 4.2 states "Since the BART analysis is based, in part, on an assessment of many of the same factors that must be addressed in establishing the RPG, it is reasonable to conclude that any control requirements imposed in the BART determination also satisfy the RPG-related requirements for source review in the first RPG planning period." In Section 9.5.1, the NDDH discussed the elimination of the BART sources from the reasonable progress goals analyses. The NDDH concluded that all controls that were reasonable were included as BART. The NDDH stands by this decision.

B) In the North Dakota Class I areas, visibility improvement is mostly due to sulfates and nitrates. The emission control requirements under the SIP will reduce SO_2 emissions by 60% and NO_x emissions by more than 25%. The uniform rate of progress goal for this planning period would only require a 23% (14 years – 60 years) reduction in visibility impairment.

The following table shows the expected change in emissions by 2018 from surrounding States and Canada.

Projected Change in Emissions 2002-2018 (%)					
	South Dakota	**Montana**	**Minnesota**	**Canada**	**North Dakota**
SO_2	-35.7	-11.8	-28.8	-6.8	-60.0
NO_x	-17.9	-26.0	-39.4	-0.8	-25.3
OC	-6.1	-3.3	-5.3	22.7	-19.4
EC	-51.1	-16.6	-28.9	75.2	-52.3
PMF	2.2	7.5	-1.3	34.8	2.0
PMC	5.2	8.8	-4.4	33.8	3.5
NH_3	0.3	1.2	33.9	-31.9	-0.3
VOC	-0.5	-0.6	2.9	-1.2	1.1
CO	-17.0	-15.9	-20.8	-11.7	-27.4

This table clearly shows that North Dakota is doing more to reduce the primary visibility impairing pollutants (SO_2 and NO_x) than the surrounding states. In addition, North Dakota is exceeding the 23% reduction calculated from the URP for this planning period for both SO_2 and NO_x. The NDDH believes that North Dakota is doing more than its fair share to address emissions reductions to reduce regional haze.

C) See Response to Comment II.A.2

D) The BART determinations were based on the five statutory factors which include: 1) cost of compliance, 2) the energy and non-air quality environmental impacts of compliance, 3) any existing air pollution control equipment in use at the source, 4) the remaining useful life of the source, and 5) the amount of visibility improvement expected from the use of the control technology. The NDDH evaluated all five factors and discussed them in the BART determinations. Cost alone was not the single factor that determined BART. For Coal Creek and Stanton Station, non-air environmental issues were a significant issue in the BART determination for NO_x and SO_2 respectively. Visibility improvement was a significant factor for NO_x at Leland Olds Station and M.R. Young Station. Existing control equipment was an important factor for determining BART for particulate matter at each BART source. The BART determinations were not made on cost alone.

Some technologies were obviously not cost effective. EPA addressed this issue in the preamble to the BART Guideline: “The interpretation of the requirements of the regional haze program reflected in the discussion above does not necessitate costly and time-consuming analyses. Consistent with the CAA and the implementing regulations, States can adopt a more streamlined approach to making BART determinations where appropriate. Although BART determinations are based on the totality of circumstances in a given situation, such as the distance of the source from a Class I area, the type and amount of pollutant at issue, and the availability and cost of controls, it is clear that in some situations, one or more factors will clearly suggest an outcome. Thus, for example, a State need not undertake an exhaustive analysis of a source’s impact on visibility resulting from relatively minor emissions of a pollutant where it is clear that controls would be costly and any improvements in visibility resulting from reductions in emissions of that pollutant would be negligible," (F.R. Vol. 70, No. 128, p.39116). The NDDH has taken this streamlined approach where the cost is obviously excessive.

E) The NDDH has included all reasonable control reduction measures in the SIP. The NDDH has shown that if all SO_2 and NO_x emissions in the State were eliminated, the uniform rate of progress for the first planning period could not be met (see Section 8.6.3.3 of SIP). This is because of the huge influence out-of-state sources have on the North Dakota Class I areas, especially Canadian sources. As noted in the SIP (Section 9.7), achieving natural conditions by 2064 is impossible without a new, zero emissions energy source. The Regional Haze SIP demonstrates that North Dakota is doing its fair share to secure reductions that will reduce visibility impairment.

Comment IV: North Dakota Must Also Propose Short-Term Average Emission Limits on SO_2 Emissions in Order to Ensure Protection of the SO_2 Increments of the State's Class I Areas.

The commenter believes that SO_2 increment is exceeded in the Class I areas of North Dakota and that short-term emission limits for SO_2 must be included in the BART permits to protect the increment.

Response: Modeling conducted by the Department (see Documents Relating to a Memorandum of Understanding between the State of North Dakota and the U.S. Environmental Protection Agency Regarding Computer Modeling Protocol for the State's PSD Program) indicates the increment for SO_2 is not exceeded. The NDDH stands by this analysis.

The SIP will reduce SO_2 emissions by nearly 106,000 tons by 2018. This will make actual emissions less than the baseline emissions. Therefore, SO_2 reductions in North Dakota will actually expand the amount of increment available for other new sources. There will be no question that emissions from sources in North Dakota (or surrounding states) do not cause concentrations of sulfur dioxide that exceed the increments.

Comment V: Other General Comments

1) Technical support is necessary to demonstrate that the Painted Canyon Improve Monitor is representative of Elkhorn Ranch Unit and the North Unit of TRNP.

2) The details of the baseline visibility calculations need to be included in the SIP.

3) The analysis of MDU Heskett cannot be putoff and must be included in the Regional Haze SIP.

Response:

1) The choice of the IMPROVE THRO1 monitor site was made by the federal agencies in 1999 when the IMPROVE network was expanded to 108 sites regionally representative of the 156 mandatory federal Class I areas. The existing monitoring site at the Painted

Canyon Overlook in the South Unit was selected to provide regionally representative coverage and data for the three units of Theodore Roosevelt National Park. Site selection followed the criteria in the Improve Particulate Monitoring Network Procedures For Site Selection, February 24, 1999, prepared by the Crocker Nuclear Laboratory of the University of California Davis, the IMPROVE contractor. The criteria included requirements that all areas represented by the site should be within 100 km of a current or potential site, whose elevation lies between the highest and lowest elevations of all areas, with a permitted variance of 100 feet or 10 percent. The site must avoid small valleys, should also avoid local pollution sources or areas with unusual meteorology and avoid nearby obstacles that could affect sample collection. The site also must be accessible for weekly sample change in all but the most severe weather. It was desirable to have existing electrical power available. The existing Painted Canyon Overlook monitoring site met all the criteria in the Procedures for Site Selection including being approximately 80 km away from the northern boundary of the North Unit and 45 km away from the Elkhorn Ranch Unit. The University of California Davis maintains the photographic and written documentation of the THRO1 site.

2) The baseline visibility calculations are taken from the WRAP TSS website. This is noted on p.34 of the SIP. The documentation for the calculations can be found in the 2006 Report for the Western Regional Air Partnership (WRAP) Regional Modeling Center (RMC) on pages 31-32. These pages will be included in an appendix to the SIP.

3) The analysis of the Heskett Station will be included in the Regional Haze SIP as a supplement. The NDDH’s analysis demonstrates that the Heskett Station is exempt from BART requirements and EPA has indicated that they agree with the Department’s determination. The supplement regarding the Heskett Station will be included in the SIP following proper adoption procedures.

RE: Comments on North Dakota's Regional Haze State Implementation Plan

Dear Mr. O'Clair:

On behalf of Dakota Resource Council, National Parks Conservation Association, Dakota Resource Council, Friends of the Boundary Waters Wilderness, Plains Justice, Dakotah Chapter of the Sierra Club, South Dakota Chapter of the Sierra Club, and Voyageurs National Park Association, we respectfully submit the following comments on the Draft North Dakota Regional Haze (RH) State Implementation Plan (SIP). Our organizations represent hundreds of North Dakotans and thousands of people throughout the nation that care deeply about protecting the air quality in our national parks and wilderness areas in the Dakotas and Midwest. We hope and strongly encourage the North Dakota Department of Health (NDDH) to revise its SIP by requiring further reductions in haze causing pollutants and otherwise advancing measures that will improve regional visibility.

For the reason stated herein, North Dakota's regional haze plan is both legally and technically deficient. The regional haze plan fails to require sufficient reductions in visibility impairing pollutants from its major polluting sources and fails to provide a long term strategy that would meet reasonable progress goals. As addressed below, the State can and must achieve much greater emission reductions in haze causing pollution with available control technologies and/or by imposing more stringent emission limits reflective of the best level of continuous emission reduction in its Best Available Retrofit Technology (BART) determinations. In addition, the long-term strategy must ensure appropriate BART requirements and other measures, including consideration of source retirement and replacement, to improve visibility in

NPCA is represented by Field Offices throughout the United States.

North Dakota and other downwind states' Class I areas to ensure that the SIP will meet its share of the emission reductions needed to meet the reasonable progress goals for the area.

Regional haze results from small particles in the atmosphere that impair a viewer's ability to see long distances, color and geologic formation. While some haze causing particles result from natural processes, most result from anthropogenic sources of pollution. Haze forming pollutants including sulfur dioxide (SO_2), nitrogen oxides (NO_x), particulate matter (PM), volatile organic compounds (VOCs), and ammonia (NH_3) contribute directly to haze or form haze after breaking down in the atmosphere. These air pollutants contribute to the deterioration of air quality and reduced visibility in our nation's national parks and wildlife refuges. Visibility impairment is measured in deciviews, which is understood as the perceptible change in visibility. The higher the deciview value is, the worse the impairment.

Through the Clean Air Act (CAA), Congress established "as a national goal the prevention of any future, and remedying of any existing, impairment of visibility in the mandatory class I Federal areas which impairment results from manmade air pollution." 42 U.S.C. §7491(a)(1). In order to meet this goal, a State is required to design an implementation plan to reduce and ultimately eliminate haze from air pollution sources within its borders that may reasonably be anticipated to cause or contribute to visibility impairment for any protected area located within or beyond that State's boundaries. In creating and implementing the plan the State has an unparalleled opportunity to protect and restore regional air quality by curbing visibility impairing emissions from some of its oldest and most polluting facilities.

Each SIP must provide "emission limits, schedules of compliance and other measures as may be necessary to make reasonable progress towards meeting the national goal." 42 U.S.C. § 7491(b)(2). Two of the most critical features of a SIP are requirements for (1) the installation of BART for delineated major stationary sources of pollution and (2) a long-term strategy for making reasonable progress towards the national visibility goal. 42 U.S.C. § 7491(b)(2)(A) & (B).

There are two Class I areas in North Dakota—Theodore Roosevelt National Park and Lostwood National Wildlife Refuge Wilderness Area. Other Class I areas impacted by North Dakota sources of air pollution include: Badlands National Park and Wind Cave National Park in South Dakota, Medicine Lake National Wildlife Refuge Wilderness Area and U.L. Bend National Wildlife Refuge Wilderness Area in Montana, Boundary Waters Canoe Area Wilderness Area and Voyageurs National Park in Minnesota, and Isle Royale National Park and Seney National Wildlife Refuge Wilderness Area in Michigan. These Class I areas preserve the region's inspiring landscapes, rare geologic formations, breathtaking water country, and diverse wildlife and vegetation. They also serve as living museums of our nation's history. Visitors from across the nation and globe are drawn to these lands and their tourist dollars benefit state and local economies.

National parks and wilderness areas are of great natural and cultural value and also engines for sustainable local capital. For example, in 2008, National Park Service units received over 274 million visits accounting for over $2.5 billion in revenue.[1] National parks support $13.3

---

[1] *See* http://www.census.gov/compendia/statab/2010/tables/10s1215.pdf, Ex. 1.

billion of local private-sector economic activity and 267,000 private-sector jobs.[2] They also attract businesses and individuals to the local area, resulting in economic growth in areas near parks that is an average of 1 percent per year greater than statewide rates over the past three decades.[3] National parks also generate more than four dollars in value to the public for every tax dollar invested.[4] Of the number of annual park visitors in 2008, approximately 516,804 people journeyed to Theodore Roosevelt National Park spending nearly half a million dollars. The same year 845,734 people visited Badlands National Park; 573,433 visited Wind Cave National Park; 221,585 visited Voyageurs National Park and 14,038 visited Isle Royale National Park.[5]

Excessive emissions from North Dakota not only obscure the region's scenic vistas Congress sought to protect, but also contribute to a host of public health problems as well as adverse impacts to wildlife and vegetation. For example, NO_x and VOCs are precursors to ground level ozone, or smog. Ground level ozone is associated with respiratory diseases, asthma attacks, and decreased lung function.[6] SO_2 pollution contributes to respiratory problems, particularly for children and the elderly, and aggravates existing heart and lung diseases. Exposure to particulate matter, made up of sulfates and nitrates, has been associated with reduced lung function, increased susceptibility to respiratory infections, chronic bronchitis, and premature death.[7] The U.S. Environmental Protection Agency (EPA) has found that in 2015, the Regional Haze Rule also will provide substantial health benefits valued at $8.4 - $9.8 billion annually -- preventing 1,600 premature deaths, 2,200 non-fatal heart attacks, 960 hospital admissions, and over 1 million lost school and work days. The total annual cost will range from 1.4 – 1.5 billion dollars.[8] These benefits are estimated under the assumption that the Regional Haze Rule will be implemented as intended-therefore these numbers may be lower if North Dakota does not revise its plan.

The regional haze program imposes a legal obligation on the State to abate the adverse visibility effects to which its haze causing facilities contribute in order to restore visibility levels to their natural conditions as mandated by the Clean Air Act. To prevent and remedy visibility impairment to the implicated Class I areas, North Dakota can and must revise and substantially improve the draft RH SIP. A strong regional haze program will not only help protect and restore treasured landscapes and the economies that rely on them but also benefit public health. With this in mind, we offer the comments below for consideration by the NDDH and strongly encourage the Department to strengthen its regional haze plan.

[8] EPA, Fact Sheet, *Final Regional Haze Regulations for Protection of Visibility in National Parks and Wilderness Areas* (June 2, 1999) at http://www.epa.gov/visibility/fs_2005_6_15.html, Ex. 3.

In addition, we note that the public comment for North Dakota's SIP was open for 30 days. It is common in other jurisdictions to provide for 45 or 60 day comment period. Given the lengthy history and technical complexity of this SIP, such an abbreviated window is not conducive to a full and fair evaluation by the public. We understand that the EPA has requested states to submit SIPs by January 15, 2010. Understandably, North Dakota would like to abide by this suggested timeline, however, the short turnaround—five business days from the end of the public comment period to the EPA deadline—does not provide NDDH an adequate amount of time to genuinely consider public comments and make needed changes to the SIP. Accordingly, we request NDDH coordinate with EPA to submit the North Dakota SIP in a timely manner without compromising full consideration of public comments.

I. The Clean Air Act and Federal Regulation Require NDDH to Abate Visibility Impairment

In 1977, the Clean Air Act declared "as a national goal the prevention of any future, and the remedying of any existing, impairment of visibility in mandatory class I Federal areas which impairment results from manmade air pollution[]" where visibility has been determined to be an important value. 42 U.S.C. § 7491(a)(1) &(2). "Manmade air pollution" is defined as "air pollution which results directly or indirectly from human activities[.]" 42 U.S.C. §7491(g)(3). Congress adopted the visibility protection program to protect the "intrinsic beauty and historical and archeological treasures" of specific public lands.[9] To protect these treasures, the regional haze program establishes a regulatory floor and requires states to design and implement programs at least as stringent as the national floor to curb haze causing emissions located within their jurisdictions. States are required to submit State Implementation Plans or SIPs if they host federally protected areas or the emissions of a facility located within a State "may be reasonably be anticipated to cause or contribute to any impairment of visibility" for a protected area located beyond their borders. 42 U.S.C. §7491 (b)(2).

The SIP must contain "emission limits, schedules of compliance and other measures as may be necessary to make reasonable progress towards meeting the national goal..." including BART requirements for all eligible sources and a long-term strategy for making reasonable progress towards meeting the national goal. 42 U.S.C. §7491(b)(2)(A) &(B).

BART is defined as an emission limitation

> ...**based on the degree of reduction achievable through the application of the best system of continuous emission reduction for each pollutant which is emitted by an existing stationary facility**. The emission limitation must be established, on a case-by-case basis, taking into consideration the technology available, the costs of compliance, the energy and non-air quality environmental impacts of compliance, any pollution control equipment in use or in existence at the source, the remaining useful life of the source, and the degree of improvement in

---

[9] *See* H.R. REP. NO. 95-294, at 203–04 (1977).

> visibility which may reasonably be anticipated to result from the use of such technology.

40 C.F.R. §51.301, emphasis added. BART limits are required for major stationary sources that were in existence on August 7, 1977 and began operating after August 7, 1962 and emit air pollutants that may reasonable be anticipated to cause or contribute to any impairment of visibility is a Class I area. 42 U.S.C. § 7491(b)(2)(A). The term "major stationary source" is defined as sources that have the potential to emit 250 tons or more of any pollutant and fall within one of 26 categories of industrial sources defined by the Act. 42 U.S.C. § 7491(g)(7). A BART-eligible source is one that meets the above criteria and is responsible for an impact on visibility in a Class I area of 0.5 deciview or more. 40 C.F.R. Part 51, Appendix Y. BART must be installed and operated no later than five years after the SIP approval. 40 C.F.R.§51.302(c)(4)(iv).

The SIP must also provide a long-term strategy for achieving reasonable progress toward meeting natural visibility conditions at mandatory Class I areas by 2064. 40 C.F.R. §51.308(d)(1)(i)(B). If a state's reasonable progress goals do not anticipate restoring visibility to natural conditions by 2064 the state must demonstrate why the goal of attaining natural conditions by the established date is unreasonable. 40 C.F.R. §51.308(d)(1)(ii). The SIP must provide for improved visibility on the most impaired days and ensure no degradation in visibility for the least impaired days. 40 C.F.R. §51.308(d)(1)(i)(B). The long-term strategy is typically a 10-15 year plan containing enforceable measures designed to meet regional progress goals. In developing its plan, the State must document the technical basis for the SIP, including monitoring data, modeling, and emission information, including the baseline emission inventory upon which its strategies are based. 40 C.F.R. §51.308(d)(3)(iii).

In developing its long-term strategy, the State must consider all anthropogenic sources of visibility impairment and evaluate different emission reduction strategies beyond those prescribed by the BART provisions. 40 C.F.R §51.308(d). The state should consider "major and minor stationary sources, mobile sources and area sources." Id. At a minimum, the state must consider the following elements:

(A) Emission reductions due to ongoing air pollution control programs, including measures to address reasonably attributable visibility impairment;
(B) Measures to mitigate the impacts of construction activities;
(C) Emissions limitations and schedules for compliance to achieve the reasonable progress goal;
(D) Source retirement and replacement schedules;
(E) Smoke management techniques for agriculture and forestry management purposes including plans as currently exist within the State for these purposes;
(F) Enforceability of emission limitations and control measures; and
(G) The anticipated net effect on visibility due to projected changes in point, area, and mobile emissions over the period addressed by the long-term strategy.

40 C.F.R. 51.208(d)(3)(v)(A)-(G).

North Dakota's regional haze plan falls far short of meeting reasonable progress goals. In fact, North Dakotas's draft regional haze plan will only bring the state to, at most, 38% of its 2018 regional progress target at Theodore Roosevelt National Park and even less than that at Lostwood Wilderness Area. Table 8.11 of the draft North Dakota State Implementation Plan (SIP) for Regional Haze. The State appears to be claiming that the national visibility goal of returning to natural visibility conditions by 2064 is unattainable, because the the majority of regional haze pollution comes from sources in Canada and outside the state. Draft North Dakota SIP for Regional Haze at 44-45. While it may be true that some of the pollution responsible for haze in the State's Class I areas is due to sources outside of North Dakota's control, that does not relieve the State from requiring industrial sources within North Dakota to be subject to BART emission limits reflective of the best degree of continuous emission reduction achievable, nor does it relieve the State from adopting other measures to improve visibility in North Dakota and other downwind states' Class I areas.

Furthermore, to ensure that reasonable progress goals are met, North Dakota should actively encourage other states and Canada to reduce emissions impairing visibility in its state and region. State-to-state consultations are part of the regional haze process, and North Dakota is well within its rights to formally request reductions from other states where appropriate. The U.S. EPA, in comments on the FLM version of the draft SIP, suggests that a three-prong approach is appropriate: "NDDH needs to be addressing sources within its control in North Dakota, requesting reductions from contributing states, and asking EPA to address the Canadian emissions."[10] To the extent that North Dakota has not undertaken each of these actions, it should do so. While there are multiple opportunities for North Dakota to pursue to ensure reasonable progress goals are attained, the State may not use emissions from outside sources as a scapegoat to avoid in-state action.

Our review of North Dakota's proposed BART emission limits and controls shows that the State has clearly not required emissions controls and limits that reflect BART for the BART-eligible sources. This is discussed in detail below. Further, the State has not required any source emission reductions or source retirements other than its proposed BART requirements to meet reasonable progress requirements. Regardless of the impacts that other sources outside of North Dakota have on regional haze in North Dakota's Class I area, North Dakota has a responsibility under the federal regional haze requirements to reduce haze causing emissions from its own sources of air emissions to do its part to meet the reasonable progress goals. Under the Long Term Strategy regulations, North Dakota is required to demonstrate that "it has included in its implementation plan all measures necessary to obtain its share of the emission reductions needed to meet the progress goals for the area" even when other states contribute to visibility impairment in the State's Class I areas. 40 C.F.R. §51.308(d)(3)(ii). Thus, the State cannot shirk its responsibility to address its sources of regional haze pollution by putting the blame on sources outside the state.

---

[10] U.S. EPA Region 8 Comments on August 21, 2009 Draft Regional Haze SIP (FLM Consultation Version), Enclosure 1, p. 5.

Further, the State has a responsibility to reduce emissions from North Dakota sources that are reasonably anticipated to impact visibility in other states' Class I areas. Minnesota is one such state, and Minnesota submitted a letter to the North Dakota Department of Health (NDDH) indicating the need for North Dakota electrical generating units to meet an average SO_2 limit of 0.25 lb/MMBtu as well as the need for NO_x emission reductions from North Dakota sources. September 19, 2007 letter from the Minnesota Pollution Control Agency (MPCA) to NDDH and other states (Appendix J.2.1. of the draft North Dakota Regional Haze SIP). NDDH did not agree with these requests and stated that "[a]dditional reductions from Minnesota sources may provide much greater reduction of visibility impacts." August 22, 2008 letter from NDDH to MPCA at 2 (Appendix J.2.2. of the draft North Dakota Regional Haze SIP.)

North Dakota could achieve additional reductions in visibility impairing pollutants from its own sources, but this draft regional haze SIP and BART limits do not require such reductions. As we will show below, North Dakota could achieve much greater emission reductions in haze causing pollution with available control technologies and/or by imposing more stringent emission limits reflective of the best level of continuous emission reduction in its BART determinations.

II. NDDH's Draft BART Determinations are Flawed

A. The SO_2 BART Limits Fail to Reflect the Degree of SO_2 Emission Reduction Achievable with the Best System of Continuous Emission Reductions.

NDDH simply has proposed the EPA's presumptive BART limits as BART at most of the BART-eligible coal-fired electric utility steam generating units (EGUs) that NDDH determined were subject to BART. Specifically, NDDH proposed SO_2 BART limits for Leland Olds Units 1 and 2, Milton R Young Unit 2, and Coal Creek Units 1 and 2 of 0.15 lb/MMBtu or 95% control. While NDDH purported to do a case-by-case evaluation of BART for each EGU, it appears that the case-by-case analyses were simply written to support the imposition of EPA's presumptive BART limits rather than to truly reflect the best level of continuous SO_2 emission reduction at each EGU.

EPA's BART Guidelines include "presumptive BART" emission limits for EGUs which were based on EPA's broad review of the control technologies and emission limits that could be met cost effectively at a wide range of coal-fired power plants. *See* Sections IV.E.4 and 5 of the BART Guidelines in 40 C.F.R. Part 51, Appendix Y. However, it must be stated that EPA's presumptive BART limits do not negate the need for the State to determine BART for each BART-eligible source on a case-by-case basis through a five factor analysis. The regulations and the Clean Air Act require the determination of BART to be source-specific. *See* 40 C.F.R. § 51.308(e)(1)(ii)(A); § 169A(g) of the Clean Air Act.

The five steps of determining BART are:

STEP 1 -- Identify All [fn 12] Available Retrofit Control Technologies,

> STEP 2-- Eliminate Technically Infeasible Options,
> STEP 3-- Evaluate Control Effectiveness of Remaining Control Technologies,
> STEP 4-- Evaluate Impacts and Document the Results, and
> STEP 5 – Evaluate Visibility Impacts.
>
> Fn 12: In identifying "all" options, you must identify the most stringent option and a reasonable set of options for analysis that reflects a comprehensive list of available technologies. It is not necessary to list all permutations of available control levels that exist for a given technology – the list is complete if it includes the maximum level of control each technology is capable of achieving.

Section IV.D. of BART Guidelines at 40 C.F.R. Part 51, Appendix Y.

Clearly, EPA's BART Guidelines require an evaluation of the top level of pollution reduction achievable with each control system evaluated in a BART analysis. EPA's BART Guidelines provide that, if a control system can be operated at a wide range of control efficiencies, "the most stringent emissions control level that the technology is capable of achieving" must be evaluated. Section IV.D.3. of the BART Guidelines at 40 C.F.R. Part 51, Appendix Y. The BART Guidelines further require that "[y]ou should consider recent regulatory decisions and performance data (e.g., manufacturer's data, engineering estimates and the experience of other sources) when identifying an emissions performance level or levels to evaluate." *Id.*

The BART Guidelines also provide:

> In assessing the capability of the control alternative, latitude exists to consider special circumstances pertinent to the specific source under review, or regarding the prior application of the control alternative. However, you should explain the basis for choosing the alternate level (or range) of control in the BART analysis. Without a showing of differences between the source and other sources that have achieved more stringent emissions limits, you should conclude that the level being achieved by those other sources is representative of the achievable level for the source being analyzed.

Id.

Further, while one can consider varying levels of pollution control in evaluation of a particular control device, one "must consider the most stringent level as one of the control options." *Id.*

NDDH did not follow these guidelines or otherwise meet the intent of the BART requirements because it did not evaluate the most stringent option available for reducing SO_2 from the State's EGUs as is discussed further below.

1. NDDH Cannot Take Into Account Projected Worst Case Sulfur Content of Coal in Setting BART Limits

For all of the coal-fired EGU SO_2 BART determinations, NDDH relied on worst case projections of sulfur content of the coal to be burned in justifying the SO_2 emission limits as BART. For example, for Leland Olds, which currently has an uncontrolled SO_2 rate exiting the boilers of 1.82 to 1.83 lb/MMBtu (2000-2004 average)[11], NDDH assumed an uncontrolled SO_2 emission rate of 3.02 lb/MMBtu[12]. There is no justification for assuming such a high uncontrolled SO_2 emission rate. Similarly, Coal Creek Units 1 and 2 burned coal with a sulfur content of 0.61% during 2003-2004[13], and yet NDDH relied on a worst case coal sulfur content of 1.1%, close to double the 2003-2004 average coal sulfur content, in proposing a BART SO_2 limit.[14]

Milton R. Young Unit 1, which currently has no scrubber, had an uncontrolled SO_2 emission rate exiting the boiler of 1.83 lb/MMBtu (2000-2004 average)[15]. Yet, for Milton R. Young Unit 2, which presumably burned the same coal as Milton R. Young Unit 1, NDDH assumed an uncontrolled SO_2 emission rate of 3.48 lb/MMBtu in proposing BART limits for SO_2.[16] Although NDDH's BART Determination for Unit 1 did not include an uncontrolled SO_2 emission rate, it also appears that NDDH assumed a higher-than-actual SO_2 rate for Unit 1. NDDH assumed 95% SO_2 removal would result in an emission reduction of 20,443 tpy.[17] Yet, the 2000-2004 average SO_2 emissions from Unit 1 were only 20,148 tpy.[18] If actual average emissions were reduced by the projected amount, Unit 1 would be emitting negative amounts of SO_2, which is an impossibility.

This shows that, not only did NDDH improperly rely on the worst case sulfur content coal in proposing BART limits, NDDH also inflated the baseline actual emissions for some EGUs to reflect higher sulfur content coal, and then calculated SO_2 emission reductions based on assumed levels of SO_2 removal from baseline emissions that never actually occurred. Thus, NDDH greatly overstated the emission reductions that would occur from implementation of SO_2 BART controls. Presumably, this was also carried over into NDDH's modeling conducted for the BART analyses as well.

In evaluating SO_2 BART for Stanton Unit 1, NDDH's approach was slightly different but had the same result of artificially inflating the proposed limit. Two scenarios

---

[17] *Id.* at 7.

[18] *Id.* at 3.

were evaluated for Stanton Unit 1, burning lignite and burning Powder River Basin, or PRB, coal. While developing a limit for burning lignite, NDDH did not rely on worst case coal. Instead, it used the average of the annual SO_2 emission rate from 2001-2004, applied its assumed SO_2 control factor for each control evaluated, [19] and then, for the proposed limit, increased the calculated controlled emission rate by 33% to arrive at a 30-day average emission limit.[20] While developing an SO_2 emission limit for burning PRB coal, however, NDDH did arbitrarily rely on higher sulfur Powder River Basin coal than currently burned at Stanton Unit 1, *and* NDDH also applied a 33% increase.[21]

The purpose of BART is to reduce emissions from current levels to improve visibility, and that purpose will be ignored if BART limits are determined based on worst case sulfur content coals of the future. As we have seen with Milton R. Young Unit 1, the nonsensical nature of this approach is highlighted when it leads to projected emission reductions that are greater than actual emissions. Because NDDH is proposing BART limits based on 30-day averages, the averaging time can allow the EGU owners to take into account variability in sulfur content of coal and still comply with the limit. Further, retrofitted and upgraded wet scrubbers can achieve much higher levels of SO_2 control than the 95% control assumed by NDDH, as is discussed further below. Thus, if an EGU owner anticipates burning a higher sulfur coal in the future, it can have its scrubber designed to achieve higher levels of SO_2 removal to meet a SO_2 BART emission limit that is set based on the coal currently burned at the EGU. There are also other options that the EGUs could use to address unusually high levels of sulfur in the coal, such as blending with a lower sulfur coal, rejecting high sulfur coal altogether, or coal drying, as has been demonstrated at the Coal Creek facility.[22] Thus, there is no justification to base SO_2 BART limits on the ultimate worst case sulfur content coal to be burned at these units.

2. The Proposed SO_2 BART Limits Fail to Reflect the Degree of SO_2 Reduction Achievable with the Best SO_2 Controls

All but one[23] of NDDH's SO_2 BART determinations requires the use of new or upgraded wet scrubbers, a technology capable of reducing SO_2 emissions by 99% or more. Despite this achievable control efficiency, NDDH simply proposed EPA's presumptive BART limits for SO_2: either 95% control or an emission limit of 0.15 lb/MMBtu. While wet scrubbers can routinely achieve the highest levels of SO_2 control, NDDH's proposed BART emission limits fail to reflect this.

---

[19] See NDDH's BART Determination for Stanton Unit #1 at 4.

[20] *Id.* at 8. Note that NDDH did not adequately justify applying a 33% increase to the controlled SO2 emission rate based on annual average uncontrolled SO2 emission rates, as we will discuss further below.

[21] *Id.* at 17, 22.

[22] To the extent that it may be capable of additional reductions of NOx and SO2 above and beyond the proposed technologies, coal drying should have been evaluated as part of the BART determinations as well. http://www.greatriverenergy.com/makingelectricity/dryfining_factsheet.pdf, Ex. 4.

[23] As discussed below, a wet scrubber was not required for Stanton Unit 1.

Wet scrubbers can achieve 99% removal efficiency. A prime example is the Chiyoda CT-121 FGD. Vendor information for this technology indicates that this scrubber has achieved 98-99% SO_2 removal even with low sulfur coal.[24] For example, the Chiyoda's bubbling jet reactor has consistently achieved >99% SO_2 removal during long-term operation at the Shinko-Kobe power plant in Japan. This facility consists of two 700-MW coal-fired utility boilers. The wet FGD was designed to achieve 0.014 lb SO_2/MMBtu (9 ppmv at 3% oxygen) on an instantaneous basis and has consistently exceeded this level of control while treating gases with inlet SO_2 concentrations of 1.78 lb/MMBtu.[25] Based on actual SO_2 emissions data, the North Dakota BART-eligible EGUs have inlet SO_2 concentrations of this level or higher. This technology has been guaranteed by Chiyoda to achieve 99% SO_2 removal on three coal-fired boilers in Japan.[26] It also has been demonstrated in the U.S. at the University of Illinois's Abbott power plant, Georgia Power's Plant Yates[27], Dayton Power & Light's Killen Unit 2,[28] and Plant Bowen Unit 3.[29] It has also been licensed for installation on several additional units in the US, including the other three units at Plant Bowen in Georgia, the other units at Dayton Power & Light's Killen plant, Dayton Power & Light's Stuart plant, and AEP's Big Sandy Unit 2, Conesville Unit 4, Cardinal Units 1 and 2, and Kyger Creek, among others.[30] Black & Veatch and Southern Company are both U.S. licensees. Further, this technology also has shown to be very effective in removing fine particulates, oxidized and elemental mercury, and acid gases, and the technology uses less energy compared to traditional wet scrubbers.

Further, Mitsubishi, another vendor of scrubber systems, reports it has guaranteed SO_2 removal efficiencies up to 99.8 percent, including for coal-fired boilers.[31, 32, 33]

Finally, a Lake Michigan Air Directors Consortium ("LADCO") and the Midwest Regional Planning Organization ("MRPO") presentation indicated that advanced FGD

technologies could achieve 99.5% control for \$1,240 to \$2,875 per ton of SO_2 removed. Ex. 15. These costs are well within the range that EPA normally considers to be cost effective in best available control technology (BACT) analyses.[34] Further, these costs are also well within the range of what other states have found to be cost effective for SO_2 BART determinations.[35]

3. The Proposed SO_2 BART Limits Should Be Expressed Multiple Ways

Many of the proposed limits are listed either as lb/mmbtu OR as percent removal efficiency. To ensure continuous compliance with "the degree of reduction achievable through the application of the best system of continuous emission reduction" over the range of possible coal sulfur content, all the SO_2 BART limits should be expressed both ways. Without a minimum required removal efficiency, the achievable SO_2 removal efficiency will not be required at lower coal sulfur content.

Further, a maximum cap on emissions should be required. EPA guidance suggests that emission limits be expressed both as a maximum allowable emission rate per unit time (e.g., lb/hr, tons/year) to reflect application of emissions controls at maximum capacity *and* as an instantaneous emission limit (e.g., lb/mmbtu). NSR Manual, pp. B.56, H.5, I.2, I.4. This is good practice for compliance purposes, and also serves as an actual time-based limit for modeling purposes.

4. NDDH's Proposed SO_2 Emission Limits Fail to Reflect BART

Thus far, three general flaws have been noted in the NDDH SO_2 BART determinations: use of worst case coal sulfur content; failure to reflect the actual removal efficiency of wet scrubbers; and failure to express limits in multiple ways. These errors and others noted below on a case-specific basis combine to allow for significantly higher SO_2 emission rates from the EGUs evaluated for BART. Table 1 below highlights this impact.

[34] \$10,000/ton in 2001, equivalent to over \$13,000/ton today. *See* expert report of Matt Haber - EPA, *Best Available Control Technologies for the Baldwin Generating Station, Baldwin, Illinois*, prepared for the United States in connection with United States v. Illinois Power Company and Dynegy Midwest Generation, Inc., Civil Action 99-883-MJR, in the U.S. District Court for the Southern District of Illinois, April 2002, p. 17, Ex. 16; Memorandum of John S. Seitz to Air Division Directors, BACT and LAER for emissions of nitrogen oxides and volatile organic compounds at Tier 2/Gasoline Sulfur Refinery Projects (Jan. 19, 2001), at 3, Ex. 17.

[35] See National Park Service Spreadsheet "EGUs with Proposed BART SO2 Controls" dated November 13, 2009, Ex. 18.

Table 1: Proposed and Appropriate BART Limits for EGUs Evaluated By NDDH

Facility	Proposed BART	Appropriate BART
Leland Olds Units 1 and 2	95% removal OR 0.15 lb/MMBtu	95 – 99% removal AND 0.03 – 0.091 lb/MMBtu
Milton R. Young Unit 1	95% removal	95 – 99% removal AND 0.035 – 0.094 lb/MMBtu
Milton R. Young Unit 2	95% removal OR 0.15 lb/MMBtu	95 – 99% removal AND 0.035 – 0.094 lb/MMBtu
Coal Creek Units 1 and 2	95% removal OR 0.15 lb/MMBtu	95 – 99% removal AND 0.03 – 0.087 lb/MMBtu
Stanton Unit 1	90% removal OR 0.24 lb/MMBtu	95 – 99% removal AND 0.02 – 0.085 lb/MMBtu

a. Leland Olds

For Leland Olds, NDDH proposed SO_2 BART limits for each unit of either 95% removal of the inlet SO_2 concentration to the scrubber or 0.15 lb/MMBtu on a 30-day average basis based on use of wet scrubbers. The proposed emission limitation of 0.15 lb/MMBtu only reflects 91.8% SO_2 removal at each unit based on the annual average of uncontrolled SO_2 emissions at each unit. Such an SO_2 removal efficiency falls far short of what is achievable with a wet scrubber at the Leland Olds units. A removal efficiency of 95% control reflects the minimum level of SO_2 removal that is achievable with a wet scrubber. Thus, at the minimum, the BART emission limit should be based on 95% removal from the annual average of the uncontrolled SO_2 emissions at each unit - or a limit of 0.091 lb/MMBtu. Because the proposed 95% removal is an alternate and not concurrent limit, the fact that NDDH has also proposed an alternative limit of 95% SO_2 removal will not ensure 95% removal is required until the uncontrolled SO_2 emissions increase significantly, to about 2.8 lb/MMBtu. Thus, it is imperative that the lb/MMBtu limit reflect no less than 95% control off of current coal in order for the BART limit to reflect at least the minimum level of SO_2 control efficiency of a wet scrubber.

Indeed, based on the discussion above regarding the SO_2 removal capabilities of a wet scrubber, a more appropriate BART limit would reflect 98-99% SO_2 removal. Even assuming the worst case uncontrolled SO_2 emissions identified by NDDH of 3.20 lb/MMBtu, 98% removal would reflect an emission limit of 0.064 lb/MMBtu. This SO_2 emission limit based on worst case coal and an achievable level of SO_2 removal would reflect 96.5% SO_2 removal from current coal – a control efficiency that is clearly achievable with a wet scrubber. Ninety-nine percent removal off of worst case coal at Leland Olds would equate to a SO_2 emission limit of 0.03 lb/MMBtu. With current coal, this would reflect 98.4% removal. This emission level and SO_2 removal efficiency has been shown to be achievable and has been achieved in practice.

The attached National Park Service spreadsheet of best available control technology (BACT) determinations for coal-fired power plants shows that BACT limits as high as the 0.15 lb/MMBtu SO_2 BART limits proposed for the Leland Olds units are unheard of. Ex. 19. The proposed permit for the Plant Washington facility requires as part of the facility's BACT limits a 97.5% SO_2 removal efficiency requirement that would apply on a 30-day rolling average regardless of the type of coal burned.[36] This facility may burn Powder River Basin coal or Central Appalachian coal or a combination of the two. The Desert Rock facility, which will burn low sulfur western coal, is subject to an SO_2 BACT limit of 0.060 lb/MMBtu on a 24-hour basis (Ex. 21), and the proposed Toquop (Ex. 22) and Ely Energy Center [37](Ex. 23) permits, both of which would burn Powder River Basin coal, also included BACT limits of 0.06 lb/MMBtu for SO_2. As Ex. 25 shows, there are numerous coal-fired units that are achieving SO_2 emission rates much lower than the 0.15 lb/MMBtu SO_2 BART limit proposed for the Leland Olds Units. The lowest SO_2 emission rates being achieved are at the Pleasant Prairie units which are emitting SO_2 at 0.021 to 0.027 lb/MMBtu with wet scrubbers.

Thus, for all of the reasons discussed above as supported by the attached documentation, BART emission limits of no higher than 0.091 lb/MMBtu and as low as 0.03 lb/MMBtu should have been evaluated as BART for the Leland Olds Units. Such limits should be readily met on a 30-day average basis, especially because higher SO_2 removal efficiencies than represented by this range of more appropriate BART limits could be met with a wet scrubber. There is no justification for increasing the emission rate determined from annual average coal characteristics to arrive at a higher 30-day average emission limit as NDDH has proposed. Thirty day average emission limits are long term average emission limits, and peaks in emissions can be smoothed out with increased SO_2 removal efficiencies and/or use of lower sulfur content coal. In addition to imposing a numerical emission limit, NDDH should also set a minimum control efficiency requirement not as an alternative limit but as a second BART limit, to ensure the achievable SO_2 removal efficiency is required regardless of the type of coal burned.

Thus, the proposed 0.15 lb/MMBtu SO_2 BART limits fall far short of reflecting the best system of continuous emission reduction at the Leland Olds units. In fact, a much more appropriate SO_2 BART limit would be in the range of 0.03 to 0.091 lb/MMBtu, 30-day average, along with an SO_2 removal efficiency requirement of no less than 95% control.

b. Milton R. Young

For Milton R. Young Unit 1, NDDH has proposed use of a wet scrubber and an SO_2 BART limit of a 95% removal efficiency from the inlet SO_2 concentration to the scrubber, to be achieved on a rolling 30-day average basis. For the reasons previously discussed and the documentation attached, 95% control does not reflect best system of continuous emission reduction of SO_2 emissions from Milton R. Young Unit 1. Instead, an SO_2 removal efficiency of 98 to 99% should be achievable with a wet scrubber and the coal to be burned at Milton R. Young Unit 1.

Along with an SO_2 removal requirement, NDDH should also impose an emissions limit. Otherwise, it is difficult for NDDH to project emissions from Milton R. Young Unit 1 for use in air modeling analyses such as PSD increment analyses or for the visibility modeling done for this regional haze SIP and subsequent SIP submissions. Based on the same reasoning provided

---

[36] Proposed Plant Washington PSD Permit (Ex. 20) at Condition 2.14.

[37] NV Energy no longer plans to build the Ely Energy Center, and officially withdrew its application to the state Public Utilities Commission in June 2009. See http://www.lvrj.com/news/breaking_news/48923992.html, Ex. 24.

above, the numerical SO_2 BART limit should be based on no less than 95% removal from the current uncontrolled emission rate of 1.88 lb/MMBtu - 0.094 lb/MMBtu. However, as discussed above, higher SO_2 removal efficiencies are achievable. Even using NDDH's worst case uncontrolled SO_2 emission rate for Milton R. Young Unit 1 of 3.48 lb/MMBtu, 98% SO_2 removal would reflect an emissions limit of 0.070 lb/MMBtu. Ninety-nine percent removal would result in an emissions limit of 0.035 lb/MMBtu. As shown in the attachments to this letter, such emission rates have been required as BACT and/or have been met in practice.

Thus, the proposed 95% SO_2 removal efficiency requirement for Milton R. Young Unit 1 falls far short of reflecting the best system of continuous emission reduction at the unit. A much more appropriate SO_2 BART limit would be in the range of 0.035 to 0.094 lb/MMBtu, 30-day average, along with a 95% or higher SO_2 removal efficiency requirement.

Milton R. Young Unit 2 is already equipped with a wet scrubber which, according to NDDH, achieves approximately 65% SO_2 control. NDDH has proposed requiring upgrades to the scrubber to achieve 95% control or meet an SO_2 emission limit of 0.15 lb/MMBtu, 30-day average, as BART for Milton R. Young Unit 2. NDDH found the costs to upgrade the scrubber to 95% control to be quite reasonable. Given the low costs for upgrading the scrubber to achieve 95% removal, it should also be cost effective to require the scrubber to be upgraded to achieve the level of SO_2 control that is achievable with a wet scrubber – up to 98-99% SO_2 removal.

Along with an SO_2 removal requirement, NDDH should also impose an emissions limit as BART for Unit 2. Because the same coal is burned and the same control efficiencies can be expected, the same analysis applies to Unit 2 as that described for Unit 1 above.
Thus, the 95% removal efficiency requirement that would apply to Unit 2 does not satisfy BART. An SO_2 emission limit in the range of 0.035 – 0.094 lb/MMBtu along with a high SO_2 removal efficiency requirement should instead be required as BART for Unit 2.

Such limits should be readily met on a 30-day average basis, especially because higher SO_2 removal efficiencies than represented by this range of more appropriate BART limits could be met with a wet scrubber. There is no justification for increasing the emission rate determined from annual average coal characteristics to arrive at a higher 30-day average emission limit as NDDH has proposed. Thirty day average emission limits are long term average emission limits, and peaks in emissions can be smoothed out with increased SO_2 removal efficiencies and/or use of lower sulfur content coal.

c. Coal Creek

For Coal Creek Units 1 and 2, NDDH proposed SO_2 BART limits for each unit of either 95% removal of the inlet SO_2 concentration to the scrubber or 0.15 lb/MMBtu on a 30-day average basis based on use of wet scrubbers. Assuming each unit achieved 68% SO_2 removal efficiencies as claimed by NDDH, then the uncontrolled SO_2 emissions at the inlet to the scrubber averaged over 2000-2005 ranged from 1.59 to 1.71 lb/MMBtu. The 0.15 lb/MMBtu emission limit only reflects 90.6% to 91.4% SO_2 removal based on the annual average of uncontrolled SO_2 emissions at each unit. Such SO_2 removal efficiencies fall far short of what is achievable with a wet scrubber at the Coal Creek units. A removal efficiency of 95% control reflects the minimum level of SO_2 removal that is achievable with a wet scrubber. Thus, at the minimum, the BART emission limit should be based on 95% removal from the annual average of the uncontrolled SO_2 emissions at each unit - or a limit of 0.080 to 0.087 lb/MMBtu. Because the proposed 95% removal is an alternate and not concurrent limit, the fact that NDDH has also proposed an alternative limit of 95% SO_2 removal will not ensure 95% removal is required until the uncontrolled SO_2 emissions increase significantly, to about 2.8 lb/MMBtu. Thus, it is imperative that the lb/MMBtu limit reflect no less 95% control off of current coal.

Indeed, based on the discussion above regarding the SO_2 removal capabilities of a wet scrubber, a more appropriate BART limit would reflect 98-99% SO_2 removal. Even assuming the worst case uncontrolled SO_2 emissions identified by NDDH of 2.92 lb/MMBtu[38], 98% removal would reflect an emission limit of 0.058 lb/MMBtu. And this SO_2 emission limit based on worst case coal and an achievable level of SO_2 removal would reflect at most 96.6% SO_2 removal from current coal – a control efficiency that is clearly achievable with a wet scrubber. Ninety-nine percent removal off of worst case coal at Coal Creek would equate to a SO_2 emission limit of 0.03 lb/MMBtu. With current coal, this would reflect 98.2% removal. These emission rates and control efficiencies are achievable as evidenced by the previously referenced and attached documentation.

Thus, for all of the reasons discussed above as supported by the attached exhibits, SO_2 emission limits of no higher than 0.087 lb/MMBtu and as low as 0.03 lb/MMBtu should have been evaluated as BART for the Coal Creek Units. Such limits should be readily met on a 30-day average basis, especially because higher SO_2 removal efficiencies than represented by this range of more appropriate BART limits could be met with a wet scrubber. There is no justification for increasing the emission rate determined from annual average coal characteristics to arrive at a higher 30-day average emission limit as NDDH has proposed. Thirty day average emission limits are long term average emission limits, and peaks in emissions can be smoothed out with increased SO_2 removal efficiencies and/or use of lower sulfur content coal. In addition to imposing a numerical emission limit, NDDH should also impose a minimum control efficiency requirement not as an alternative limit but as a second BART limit, to ensure the achievable SO_2 removal efficiency is required regardless of the type of coal burned. Therefore, a SO_2 control efficiency requirement should also be imposed as BART, no less than 95% control.

d. Stanton Unit 1

For Stanton Unit 1, NDDH proposed as BART for SO_2 the use of a spray dryer with a fabric filter and an SO_2 emission limit of 0.24 lb/MMBtu or an SO_2 removal efficiency of 90%, both on a 30-day rolling average basis. This emission limit was derived assuming 90% removal from the highest calendar year average SO_2 emissions of 1.81 lb/MMBtu, increased by 33% to adjust from an annual average to a 30-day average. NDDH has provided absolutely no justification for this 33% increase. Given that the limit is based on the worst year of uncontrolled SO_2 emissions, that the assumed control efficiency of the spray dryer is much lower than what can actually be achieved in practice with a spray dryer, and that Stanton Unit 1 also

---

[38] This was calculated from the table of future case emissions rates and the expected control efficiencies of the various options evaluated, Coal Creek BART Determination at 10.

burns Powder River Basin (PRB) coal which has much lower uncontrolled SO_2 emissions, there is no valid justification for NDDH to increase the derived emission rate reflective of 90% control by 33%.

Spray dryers can achieve greater than 90% SO_2 removal. There have been several proposed low sulfur PRB coal-fired power plants that have proposed to use dry scrubbers to meet PSD requirements and that are subject to much lower SO_2 BACT limits than 0.23 lb/MMBtu. Those facilities include the Newmont Nevada TS power plant, the proposed White Pine power plant[39], Toquop, and the Dry Fork power plant. The Newmont Nevada power plant is subject to a minimum 95% SO_2 removal efficiency requirement when burning coal with a sulfur content equal to or greater than 0.45% and is subject to a minimum 91% SO_2 removal efficiency when burning coal with sulfur content less than 0.45%.[40] This facility is currently operating in compliance with its limits. The Newmont Nevada plant is also subject to an SO_2 BACT limit of 0.065 lb/MMBtu when burning coal with less than 0.45% sulfur content. The proposed Toquop permit included an SO_2 BACT limit of 0.06 lb/MMBtu on a 24-hr average basis.[41] The Dry Fork power plant in Wyoming, which is also currently under construction, will burn Powder River Basin coal, will be equipped with a dry scrubber, and is subject to an SO_2 BACT limit of 0.07 lb/MMBtu.[42] Other examples of low SO_2 emission limits and high SO_2 removal rates being required as BACT can be found in the National Park Service's spreadsheet of BACT determinations for coal-fired electrical generating units, Ex. 19.

Regardless of whether NDDH underestimated the effectiveness of a spray dryer, a wet scrubber can remove an even greater amount of SO_2 than a spray dryer. Although NDDH did not find the costs of a wet scrubber at Stanton Unit 1 to be excessive, NDDH discounted the use of a wet scrubber because it determined the increased amount of SO_2 removed would not provide that much of a visibility improvement. The cost effectiveness of the wet scrubber at 95% removal for Stanton Unit 1 was actually quite reasonable at $1,480 per ton of SO_2 removed. Stanton BART Determination at 5. As shown in the National Park Service spreadsheet of BART determinations (Ex. 18), there are several instances where wet scrubbers were required to meet SO_2 BART requirements with similar or even higher costs on a $/ton of SO_2 removed basis, specifically Clay Boswell Unit 3 ($1,640/ton) and Naughton Units 1 ($1,707/ton) and 2 ($1,700/ton). There are also several instances of dry scrubbers being required as BART for SO_2 with even higher cost effectiveness values than $1,480 per ton, including Boardman ($3,053/ton), Martin Drake Units #6 ($2,765/ton) and #7 ($2,276/ton), Dave Johnston Units #3 ($1,848/ton) and #4 ($4,743/ton), and Silver Bay ($7,309/ton), among others. Thus, the cost of a wet scrubber at Stanton Unit 1 is cost effective and is well within the range of the costs required at other similar EGUs to meet BART for SO_2. Given that North Dakota is far from meeting reasonable progress goals in remedying existing visibility impairment, NDDH must require as BART the most effective SO_2 control – especially when it is as cost effective as a wet scrubber would be at Stanton Unit 1.

---

[39] In March 2009, LS Power "indefinitely postpone[d]" plans to build the White Pine power plant. http://www.lasvegassun.com/news/2009/mar/05/second-coal-fired-plant-canceled-nevada/, Ex. 26.

[40] *See* Section V.A.2.a.8. of Newmont Nevada Permit, Ex. 27.

[41] *See* Section V.A.2..a.(8) of draft Toquop permit, Ex. 22.

[42] *See* Dry Fork PSD Permit, Ex. 28.

In addition, as discussed above and in the attached exhibits, wet scrubbers can achieve higher than NDDH's assumption of 95% removal, as high as 98-99% SO_2 removal. If a proper SO_2 removal efficiency was taken into account, the cost effectiveness of a wet scrubber at Stanton Unit 1 would be even lower and the benefit to visibility in the affected Class I areas would be even greater.

Because the cost of a wet scrubber at Stanton Unit 1 is cost effective and because a wet scrubber will reduce SO_2 emissions to a much greater extent than a dry scrubber, NDDH must require the use of a wet scrubber as BART for SO_2 at Stanton Unit 1.

Along the same lines as our previous comments, the SO_2 BART limit with a wet scrubber should be no less than 95% removal off of current coal, or an emission limit of 0.085 lb/MMBtu. As previously stated and shown by the attached exhibits, 98-99% SO_2 removal should be achievable with a wet scrubber, which would equate to emission limits of 0.034 lb/MMBtu to 0.02 lb/MMBtu. These emission rates and control efficiencies are achievable as evidenced by the previously referenced and attached documentation.

Thus, for all of the reasons discussed above, a wet scrubber should have been required as BART for Stanton Unit 1. SO_2 emission limits of no higher than 0.085 lb/MMBtu and as low as 0.02 lb/MMBtu should have been evaluated as BART for the Stanton Unit 1. Such limits should be readily met on a 30-day average basis, especially because higher SO_2 removal efficiencies than represented by this range of more appropriate BART limits could be met with a wet scrubber. Thirty day average emission limits are long term average emission limits, and peaks in emissions can be smoothed out with increased SO_2 removal efficiencies and/or with the use of lower sulfur content coal. In addition to imposing a numerical emission limit, NDDH should also set a minimum control efficiency requirement not as an alternative limit but as a second BART limit, to ensure the achievable SO_2 removal efficiency is required regardless of the type of coal burned. This is especially important for Stanton Unit 1 which may burn two different types of coal with different uncontrolled SO_2 emission rates. The minimum control efficiency requirement should be no less than 95% control for a wet scrubber.

5. There Are Other Benefits to NDDH Requiring Stringent SO_2 BART Limits that NDDH Must Take Into Account

Along with providing for improved visibility, there are also other environmental benefits to higher SO_2 removal requirements. Specifically, very low SO_2 emission rates, on the order of single digit parts per million (ppm) concentrations, will be needed for the effective removal of carbon dioxide (CO_2) from the gas stream. Many of the amine-based CO_2 control methods currently under development are very sensitive to sulfur and thus require very low SO_2 inlet concentrations, on the order of 1 to 2 ppm.[43] It will be more cost effective and operationally simpler to design and install controls in one retrofit program.

---

[43] Chuck Dene, Lesley A. Baker, and Robert J. Keeth, FGD Performance Capability, Mega 2008, Ex. 29.

It is well recognized that it is not a matter of if but when Congress and/or EPA will mandate CO_2 reductions from industrial sources such as EGUs. Thus, if a more effective SO_2 control technology and more stringent control requirements will better prepare North Dakota's EGUs to be able to effectively remove CO_2 in the future, that must be taken into account in the BART analysis as another environmental benefit of a lower SO_2 emission limit. Indeed, as described above, there are wet scrubber technologies available that can remove 99+% of the SO_2.

Further, lower emissions of SO_2 that are achievable with wet scrubbers also equate to lower $PM_{2.5}$ concentrations since there will be less SO_2 in the air to contribute to sulfate formation. Studies have demonstrated that sulfate addition to sulfate-limited water bodies or wetlands can increase the transformation of mercury to its neurotoxic form, methylmercury.[44] Thus, with lower SO_2 emissions from North Dakota's EGUs, the result should be less sulfate deposition which should decrease methylization of mercury.

All of the above must be taken into account by NDDH in proposing SO_2 BART limits for the State's BART-eligible EGUs. NDDH must require the best designed and most effective SO_2 controls on its BART-eligible EGUs – i.e., wet scrubbers designed to achieve 98-99% SO_2 removal – to meet the regional haze requirements of the Clean Air Act for the State's Class I areas.

B. NO_x BART Comments

The following comments are provided with respect to the proposed NO_x BART levels in the draft RH SIP proposed by NDDH. At the outset, it must be noted that technical issues pertaining to NO_x BART for the various coal-fired electric utility units, which are the major NO_x sources affecting visibility and regional haze in Class I areas in North Dakota and neighboring states, have been under discussion, in one form or another going back to roughly 2006. As such, it is impossible to provide meaningful comments on all aspects of NO_x BART in the allowed 30-day time period for public comment. This is particularly so given that the public comment period (ending January 8, 2010) coincided with major holidays and year end vacation periods, minimizing the ability to fully flesh out important aspects of the proposed BART. As such, the focus of the comments is on the following most important issues:

(a) The erroneous determination that high dust Selective Catalytic Reduction (HDSCR) is technically infeasible at each and any of the coal-fired electric utility units under consideration;
(b) The erroneous determination that tail end or low dust SCR (TESCR or LDSCR) are rejected based on cost ineffectiveness considerations at each and any of the coal-fired utility units under consideration.

---

[44] *See, e.g.*, Jeremiason, Jeff D. et al., Sulfate Addition Increases Methylmercury Production in an Experimental Wetland, Environ. Sci. Technol., 2006, 40, 3800-3806 (Ex. 30); See also Krabbenhoft, David P. *et al.*, Unravelling the Complexities Mercury Methylation in the Everglades: The Use of Mesocosms to Test the Effects of "New" Mercury, Sulfate, Phosphate, and Dissolved Organic Carbon, available at http://sofia.usgs.gov/projects/merc_carbon/hgmeso_geer03abs.html, Ex. 31.

The net result of rejection of SCR of any design at the coal fired units is that otherwise large NO_x reductions from these major sources, which could have accrued, and benefitted air quality in North Dakota and neighboring states, will not occur. That this outcome is based on erroneous regulatory and technical reasoning is untenable.

It should be noted that, due to the lack of time, the following issues could not be extensively commented upon. However, they are noted in summary or brief form below. We reserve the right to provide additional comments on these and related topics at a later date:

(a) The process by which North Dakota selected the NO_x sources to be analyzed as part of the SIP.
(b) The process by which certain emission units were selected at sources and source categories which were found to significantly impact visibility, either as part of being BART-eligible sources or under the Reasonable Progress provisions of the applicable regulations.
(c) The lack of technical basis for the assumed control efficiencies in most of the NO_x control options. For example, in the case of SCR, efficiencies of 80% or 90% or 93% are variously assumed, without basis or consistency.
(d) The lack of any support whatsoever for the level of cost-effectiveness which appears to be the basis for rejection of technologies (such as TESCR and LDSCR) on cost-ineffectiveness grounds. Nothing in the EPA guidelines for BART determinations established a bright-line cap on the cost-effectiveness expressed on \$/ton reduced grounds. References to EPA's presumptive limits (\$1,300/ton reduced) as a cap in this regard is fatally flawed. Numerous BART determinations in other states RH SIPs have accepted NO_x controls at levels higher than this level.[45]
(e) The improper use of incremental cost-effectiveness, as a tool to reject technologies (such as TESCR and HDSCR) which are otherwise cost-effective, even under the flawed and worst-case analyses presented by the utilities (and accepted by the State). EPA has noted the error in relying on this metric in its comments. However, such direct and express criticism seems to have had no effect in ND's analysis and proposal.
(f) The lack of discussion and analysis of cost-effectiveness expressed in terms of \$/dv improved. This metric, clearly relevant in this regard, will allow comparisons of cost-effectiveness for North Dakota sources with those from other sources in other states subject to RH NO_x reductions.
(g) The lack of explicit discussion of how each of the 5 statutory factors was used or weighed in the BART determinations.
(h) The lack of support for how details such as the BART limits themselves were arrived at in terms of their averaging time. In other words, why shorter averaging times (such as 7-day or 24-hour averages) were not considered – especially given that visibility impacts can occur on short durations.
(i) The exception accorded to startup and shutdown periods, even though 30-day averaging time periods are used for the recommended BART limits. This is without technical and regulatory basis.

---

[45] See National Park Service Spreadsheet "EGUs with Proposed BART NOx Controls" dated November 13, 2009, Ex. 32.

Finally, it should be noted that there was insufficient time to properly critique NO_x BART for the other NO_x sources (other than the utility boilers).

1. High Dust SCR (HDSCR) is Technically Feasible

As noted earlier, the applicability of SCR as NO_x control – universally agreed to by all parties as being the technology with the highest degree of NO_x reduction potential (upwards of 90%, after consideration of in-boiler NO_x controls such as low NO_x burners or over-fire air etc.) – has been the subject of technical discussion in North Dakota since at least 2006. Not only were such discussions central to the consent decree implementation at the Milton R. Young units, but they were also part of the initial BART submittals of the various affected companies.

It appears that after opposing any type of SCR (high dust, tail end or low dust) for years on technical infeasiblity grounds, the State of North Dakota finally revised its position recently that tailend and low dust SCR were technically feasible after all. While this is a positive shift, we believe that the State has not provided a technical or regulatory basis for continuing to reject the even most promising (and likely more cost-effective) option that HDSCR is also technically feasible.

Since the State's position regarding HDSCR is the same in the case of any of the BART analyses (see Appendix B.5), comments on this aspect are provided in general, without particular reference to specific units. It should be noted that the State's position is an amalgam of all of the arguments that have been pushed consistently by the affected units, their owners, their technical consultants (Burns and MacDonnell, Sargent and Lundy, and others) with regards to SCR for the last many years.

The central issue seems to be the use (or lack of use) of technical judgment on the part of the State. An important secondary issue seems to be the State's rejection of technical arguments and support from a most important source – namely the vendors of SCR catalysts themselves.

The State's technical infeasibility rejection of HDSCR boils down to a circular argument. Basically, the State has taken the following position:

(a) that each of the boilers at issue burns some form of North Dakota lignite coal (either exclusively or in combination with other fuels such as Powder River Basin (PRB) sub-bituminous coal);
(b) that North Dakota lignite is both unique and highly variable in its properties – such as heating value, ash content, sodium content, sulfur content, moisture content, etc. In fact, in the State's view, it is so unique that there are no other similar or comparable aspects to any other lignites or brown coals anywhere in the world nor any other fuels such as biomass or wood;
(c) that HDSCR has not been applied at any North Dakota lignite fired units (which are only used in North Dakota utility units) to date (with the one, flawed exception at Coyote back many years ago, which will be discussed shortly);

(d) that since HDSCR has not been applied at any North Dakota lignite fired units successfully and for many years, there is no basis to conclude that it can be used successfully.

The circular argument is obvious. NDDH basically wants proof that HDSCR will work successfully before allowing HDSCR to be implemented – yet it demands that this proof be obtained from the very universe of sources (and only those) which are the subject of its analysis. This is akin to saying that a control technology will not work at a particular facility because it has not been tried there yet.

It is not unusual for "new" technologies to be faced with such first-time applicability challenges in a particular source category. Of course, HDSCR is not "new" in any traditional sense - it has been demonstrated successfully in other, closely related source types. In fact, implementation of BART[46] relies on the fact that emissions reductions will often accrue from first-time application of "new" technologies to various source categories. Otherwise the inherent "technology-forcing" aspect of BACT and BART would not be realized.

There is no debate that HDSCR has been successfully to all boiler types in other coal-fired applications including bituminous coals, sub-bituminous coals, other lignites, brown coals, biomass, and combinations of these fuels. There is also no debate that HDSCR has been successfully applied to all of the boiler technologies at issue here – namely cyclone, tangential fired and wall fired boilers.

Thus, the only issue is whether, in light of its widespread and continued successful use in closely related sources types such as other coal-fired applications, HDSCR can be successfully "transferred" to North Dakota lignite fired units that are either cyclone or tangential fired or wall fired (which is the universe at issue at the present time)? We believe that the overwhelming evidence in the record suggests that the answer to this question is Yes.

Typically, first-time applicability is the result of careful and proper technical consideration by the regulatory agency of the following:

(a) reliance on technology-transfer from other similar sources, broadly construed;
(b) proper reliance on pilot tests, if such tests were properly designed and conducted;
(c) reliance on key technology suppliers such as vendors, who bear the risk of failure – commercially, and reputationally; and
(d) fundamental assessment of the likely risk factors that may make the technology a failure.

Of course there will be risks inherent in the first-time application of any technology (new or old) to a new source category. We do not believe that demanding zero-risk as a pre-requisite is proper. Yet, we believe that this is exactly what North Dakota seems to want in its circular argument discussed above.

---

[46] We note that implementation of BART can and should necessarily encompass a review of relevant BACT analysis.

We believe that North Dakota has improperly disregarded key aspects of the above considerations, in particular the rejection of explicit assurances from at least two experienced and reputable SCR catalyst vendors, as far back at 2007/2008, that HDSCR could be installed at the units at issue. Substituting its own judgment in place of such vendors was improper. Relying only on industry-funded researchers, engineering companies and consultants (who are not technology providers) is also improper.

Basically, for the last 4 years, and in spite of much evidence to the contrary, North Dakota has chosen to disregard the plain fact that HDSCR can be successfully applied to each and every unit at issue. Of course, such application will require case-by-case design and analysis. Of course, such application will inherently involve some technical risk. To the extent that such risks can be mitigated by coupon tests, or pilot tests, these should be conducted either at the units or at vendor locations. That each utility was vehemently opposed to any such tests, relying on false regulatory arguments that these somehow violate how BART is determined, underscores the outcome-determinative nature of the present proposed analysis. The fact is that BART allows for technology transfer. We know of no successful technology transfer that is not preceded by prudent engineering judgment, supported by appropriate testing. Thus, excluding the possibility of any such type of testing equates to reading-out technology transfer from the definition of BART – which directly contradicts EPA guidance and Congressional intent.

Below, we provide some comments on key technical concerns raised by the State in attempting to support its position that HDSCR is not technically feasible.

a. Variability of Fuel Composition

The State notes that North Dakota lignites (or lignite from a particular mine, such as the Center Mine, the source of the Milton R. Young units) are highly variable in heat and ash content and in the constituents that make ash, and that such variability will affect SCR design and operation. While this may be true, it is true of all coals, worldwide. We know of no coal-fired boiler designer/operator or SCR designer/operator who does not face fuel variability. However, such variability is no reason to conclude that HDSCR will be precluded from successful application. In fact, designers routinely factor in such variability such that equipment can operate over a wide range of variability. Thus, it is a matter of proper design, anticipating such variability, which is required by a case-by-case analysis. Frankly, pointing to such variability as a reason for technical infeasibility of HDSCR shows the weakness of the State's argument.

b. Results of the Coyote Pilot Testing

The State correctly states that "the only pilot testing that has ever been conducted on a unit firing North Dakota lignite was at the Coyote stations. The pilot scale SCR was plugged after 2 months and little useful data was obtained." In fact, the failure of the Coyote stations test is noted as a central point in the State's determination that HDSCR cannot be successful. Yet, in key respects, the State intentionally or otherwise misrepresents these tests and their conclusions. This is puzzling because the State correctly notes that "the pilot testing....in hind-sight, was ill-designed for a unit combusting North Dakota lignite..." In fact, it is undisputed that this test was poorly designed and executed for the following reasons:

(a) The catalyst used at the Coyote station test was previously used at the Baldwin station. While it was supposedly cleaned between tests, the nature of such cleaning and its effectiveness are unknown. It is more than likely that the catalyst was impaired before tests even began at Coyote station. At any rate, it is undisputed that it was not new or fresh catalyst;

(b) The catalyst design was improper with regard to pitch, measure of cell spacing that influences gas flow and ash deposit. That resulted in rapid plugging in a short amount of time. As a result, no deactivation data were obtained. There is no support whatsoever that this type of catalyst or the same pitch would be proper or be used in any of the HDSCRs at issue. Improperly disregarding the specific aspects of why these tests failed but continuing to make general statements, is the very definition of poor judgment.

Just on this basis alone, the Coyote station "tests" and any conclusions therefrom should be rejected. It is a simple data validation issue. In particular, any conclusions relating to catalyst blinding or plugging etc., which depend on catalyst geometry, from these flawed tests, should definitely be rejected. Knowing these flaws and purposely choosing to ignore them while relying on these tests points to poor technical judgment on the part of the State.

In fact, as the State well knows, the prior Baldwin tests also concluded that HDSCR would not work for those cyclone boilers. Yet, after proper evaluation, the Baldwin station proceeded to install HDSCR and such units have been operating successfully, now for many years. This provides further support for rejection of the Coyote tests.

Finally, several of the SCR and catalyst vendors (Alstom, Babcock Power, CERAM, Halder-Topsoe), who were aware of the Coyote tests, were still willing to provided proper guarantees for HDSCR. The State chose to disregard this.

To the extent that the State is worried about popcorn ash plugging, these issues have been widely and successfully addressed in numerous other HDSCR installations using simple technologies such as ash removal systems (e.g. mechanical screens).

c. Sodium

The State notes that the combustion of North Dakota lignite produces or can produce soluble sodium compounds, which cause more severe catalyst deactivation than insoluble sodium compounds. However, the State fails to show how, under the actual operating temperatures in a HDSCR location, such compounds can penetrate or deposit on the catalyst and if they did so, why they could not be addressed by mitigation measures such as washing (since they are soluble). At least one of the catalyst vendor has noted that "sodium is not a poison to catalyst at SCR operating temperatures..." The critical issue is not whether, as a general matter, sodium can cause deactivation, but whether, under actual operating conditions, it would do so. Without factoring in the operating temperatures, such a statement or concern is meaningless. Since, at the expected operating temperatures, such sodium compounds will generally not condense, this mechanism is speculative and unlikely. At under conditions where such condensation is an issue (such as during shutdown), proper design such as by-pass, can be used. Finally, even if some condensation occurred, it can be mitigated using water washing.

d. Temperature Variations

In some units (such as the Milton Young cyclone unit), the State is concerned that the temperature variation of the flue gas entering a HDSCR will adversely affect its performance. We note that this, again, is a matter of proper design and evaluation. Why there are such large temperature variations and what is causing them are legitimate design issues that need to be resolved on a case-by-case basis. Perhaps additional boiler changes in the backpass, air preheater, or economizer may be needed. But the need for such changes does not eliminate HDSCR. No regulation or guidance contemplates that application of air pollution control technology would be so seamless as to preclude any other changes to the emissions source. To provide this argument in support for technical infeasibility for HDSCR has no merit.

e. Catalyst Erosion

The State is concerned that HDSCR catalysts can erode and that there are "unresolved issues regarding catalyst erosion…." Notwithstanding that all SCR catalysts erode to some extent and that this is accounted for as part of the design of any SCR, the State's position is not substantiated by any data. SCRs have been exposed to bituminous coal combustion ash as high as 40%. Ash contents in coal comparable to that of North Dakota lignite have used SCR for many years.

f. Lack of Vendor Guarantees

The Department states that "vendors cannot without further pilot testing, guarantee SCR system performance for M.R. Young Station boilers firing North Dakota lignite." This statement is simply incorrect as both CERAM and Haldor Topsoe clearly stated, way back in 2007 and 2008, that they would be willing to offer industry standard guarantees for an HDSCR system installed at the Milton R. Young Station, which includes a cyclone boiler. The guarantees that were offered were consistent with those that are typical in the utility industry (i.e., up to contract value), in spite of claims to the contrary by the State and consultants to the utility companies. Making an issue of guarantees in the face of explicit guarantees already being offered by the actual catalyst suppliers underscores the nature and weakness of the State's argument against HDSCR.

In summary, we believe that it is grossly erroneous to conclude the HDSCRs are technically infeasible for any of the utility boilers that are at issue in the RH SIP. For this reason alone, the draft SIP and all of the NO_x limits proposed as BART are flawed and the analysis needs to be redone. In redoing the analysis, the following approach should be followed:

(a) Request engineering quotes for HDSCR systems from experienced SCR and catalyst vendors, capturing up-to-date developments in catalyst design and mitigation strategies for the potential problems that may arise in installation. Determine a range of HDSCR control effectiveness values and associated costs, as appropriate for each unit;

(b) Do the above in a public process so that the problematic and procedural issues inherent in the prior process (in which vendors were essentially brow-beaten by industry consultants) when vendors were contacted, are avoided. Involve U.S. EPA, the National Park Service, and other relevant regulatory agencies in this process;
(c) Lay out clear guidelines for the cost-effectiveness criteria that will be used in a comparison of cost effectiveness of HDSCR. At a minimum, this should include the absolute cost effectiveness expressed as \$/ton NO_x reduced and \$/deciview of visibility improvement (considering all of the unit's impacts at all affected Class I areas). Secondarily, this can include considerations of incremental cost-effectiveness. However, incremental cost-effectiveness is a secondary and not a primary criterion. These guidelines should be clearly stated independently of the HDSCR analysis and should be supported. Some comments on this aspect are provided later.
(d) Conclude whether HDSCR is cost-effective at each unit and therefore whether it is BART or not.

2. TESCR and LDSCR Are Cost Effective.

As noted above, in rejecting HDSCR, we believe that the State has fatally compromised its NO_x BART analysis and, therefore, the analysis should be redone.

Separately from that, although the State did require that TESCR and LDSCR be considered since they are technically feasible (after incorrectly arguing that they are not for years), these technologies were rejected on cost-effectiveness grounds. We believe that this rejection was in error for the following reasons:

(a) A lack of transparency of how the costs were developed. In no case were detailed cost-estimates provided in the record, along with the associated design of the SCRs. Rather, gross values of SCR in \$/kW terms were assumed along with numerous other assumptions, stated and unstated. Without this information, there is insufficient data for analysis of cost effectiveness by the public or any agency. The SIP should be considered incomplete without this information. Thus, the cost figures arrived at (and the associated control efficiencies) are unreliable and are assumed to be higher than actual.
(b) An incorrect reliance on incremental cost-effectiveness as the metric for cost effectiveness;
(c) A lack of stated and defensible cost-effectiveness metrics by the State.

We believe that higher values of total (not incremental) cost-effectiveness are appropriate. Higher measures of cost-effectiveness than those used by the State have been used in both BART analyses and rule-making instances, over \$10,000/ton in some instances.[47] As

---

[47] See National Park Service Spreadsheet "EGUs with Proposed BART NOx Controls" and "EGUs with Proposed BART SO2 Controls" dated November 13, 2009, Ex. 32 and Ex. 18, demonstrating BART determinations at cost effectiveness up to \$7,309/ton (SO2) and \$3,778/ton (NOx); \$10,000/ton was determined to be cost effective for BACT in 2001, equivalent to over \$13,000/ton today. *See* expert report of Matt Haber - EPA, *Best Available Control Technologies for the Baldwin Generating Station, Baldwin, Illinois*, prepared for the United States in connection with United States v. Illinois Power Company and Dynegy Midwest Generation, Inc., Civil Action 99-883-MJR, in the U.S. District Court for the Southern District of Illinois, April 2002, p. 17, Ex. 16; Memorandum of John S. Seitz

noted by EPA itself in its comments in the present instance, there is no justification to limit the cost-effectiveness to just those values considered in the examples of presumptive-BART, as has been done by the utilities and the State.

Considering a higher range of cost-effectiveness, the application of TESCR and/or LDSCR is cost-effective in many cases in the instances where considered. This is in spite of the lack of transparency in the costs themselves as noted above. In other cases where it is not cost-effective at this metric, we stand by our comment on the lack of transparency. We also note that at this level of cost-effectiveness, other NO_x control technologies that were incorrectly rejected (such as SNCR) are also cost-effective.

Thus, there is no justification for rejecting TESCR or LDSCR as NO_x BART. Therefore, the proposed BART limits are flawed and the analysis should be rejected.

3. Specific Comments on Each NO_x BART Analysis

Our additional comments on the seven specific BART utility boilers NO_x BART analyses are noted below. However, these are not extensive in view of the lack of time provided for public comment. The brevity of these comments should not be interpreted as an indicator of agreement with the analyses or the conclusions presented in the proposed RH SIP. As such, we stand by comments made by others including the U.S. EPA in specific instances, particularly as related to the incorrect assumptions in the design and cost analyses present by industry consultants including Sargent and Lundy.

Basin Electric Power Cooperative Leland Olds Station Unit 1 - This unit is a wall-fired pulverized coal boiler combusting primarily lignite coal (80-100%) and PRB subbituminous coal (20-0%). The existing nitrogen oxides control equipment is low NO_x burners installed in 1995. The BART selected by the State is a limit of 0.19 pounds per million Btu of heat input on a 30-day rolling average basis. This limit is to be achieved by the installation of selective noncatalytic reduction (SNCR) and basic separated overfire air (SOFA). We believe that these technologies do not constitute BART and that HDSCR was improperly rejected in the analysis. We also believe that LDSCR with reheat that was considered in the analysis was improperly rejected given that its cost-effectiveness, as calculated with non-transparent cost data, was in line with the range of other cost-effectiveness decisions.

Basin Electric Power Cooperative Leland Olds Station Unit 2 - This unit is a cyclone boiler combusting primarily lignite coal (80-100%) and PRB subbituminous coal (20-0%). The unit has no existing nitrogen oxides control equipment. The BART selected by the State is a limit of 0.35 pounds per million Btu of heat input on a 30-day rolling average basis. This limit is to be achieved by the installation of selective noncatalytic reduction (SNCR) and advanced separated overfire air (ASOFA). We believe that these technologies do not constitute BART and that HDSCR was improperly rejected in the analysis. As noted above for Unit 1 for this station, LDSCR was improperly rejected as BART based on erroneous cost criteria.

---

to Air Division Directors, BACT and LAER for emissions of nitrogen oxides and volatile organic compounds at Tier 2/Gasoline Sulfur Refinery Projects (Jan. 19, 2001), at 3, Ex. 17.

Great River Energy Coal Creek Station Unit 1 and Unit 2 - Unit 1 and Unit 2 are identical tangentially-fired pulverized coal boilers combusting lignite coal. The existing nitrogen oxides control equipment is low NO_x burners (LNB) and separated overfire air (SOFA). The BART selected by the Department for each unit is a limit of 0.17 pounds per million Btu of heat input on a 30-day rolling average basis. This limit is to be achieved by the use of the existing low NO_x burners (LNB) and modified/additional separated overfire air (SOFA). We believe that these technologies do not constitute BART and that HDSCR was improperly rejected in the analysis. We also believe that an improper value (80%) was used as the control efficiency for LDSCR, resulting in an erroneously high cost-effectiveness for LDSCR.

Great River Energy Stanton Station Unit 1 - Unit 1 is a wall-fired pulverized coal boiler combusting PRB subbituminous coal and lignite coal. The existing nitrogen oxides control equipment is low NO_x burners. The BART selected by the State is a limit of 0.29 pounds per million Btu of heat input on a 30-day rolling average basis when burning only lignite coal, a limit of 0.23 pounds per million Btu of heat input on a 30-day rolling average basis when burning subbituminous coal, and a weighted average emission limit when burning a combination of lignite and subbituminous coal. These limits are to be achieved by the installation of low NO_x burners (LNB), overfire air (OFA), and selective noncatalytic reduction (SNCR). We believe that these technologies do not constitute BART and that HDSCR was improperly rejected in the analysis. We also believe that LDSCR, which was considered technically feasible, was improperly rejected given its cost-effectiveness of $6,475 is in the range of appropriate cost-effectiveness values.

Minnkota Power Cooperative Milton R. Young Station Unit 1 and Unit 2 - Unit 1 and Unit 2 are both cyclone boilers burning lignite coal. The units have no existing nitrogen oxides control equipment. The BART selected by the State for Unit 1 is a limit of 0.36 pounds per million Btu of heat input on a 30-day rolling average basis and for Unit 2 is a limit of 0.35 pounds per million Btu of heat input on a 30-day rolling average basis. These limits will be achieved by the installation of selective noncatalytic reduction (SNCR) and advanced separated overfire air (ASOFA). These technologies and the limits contained in the draft SIP are identical to the provisions in the consent decree. The State has done nothing more than take what has already been required by law and rolled that into the BART analysis. We believe that this does not constitute an adequate BART analysis.

Specifically, we believe that the selected technologies do not constitute BART and that HDSCR was improperly rejected in the analysis. We also believe that LDSCR and TESCR, which were considered technically feasible, were improperly rejected given cost-effectiveness values of $3,906/$5,591 (LDSCR) and $4,835/$6,266 (TESCR) for Unit 1 and $4291/$6382 (LDSCR) and $4,948/$7081 (TESCR) for Unit 2 are in the range of appropriate cost-effectiveness values.

II. NDDH Has Failed to Include Other Emission Reduction Requirements as Part of Its Long Term Strategy to Meet Reasonable Progress Requirements Which Must Be Designed to Meet the Goal of Natural Visibility Conditions by 2064

Although NDDH evaluated additional controls at Antelope Valley Units 1 and 2, Coyote Station, the Great Plains SynFuel Plant, and the Tioga Gas Plant, NDDH did not ultimately propose any additional emission reductions as part of its long term strategy to meet reasonable progress goals. NDDH placed heavy focus on these additional controls based on costs, and NDDH discounted all additional controls at these facilities due to its determination of a limited visibility benefit to be gained from the controls. Draft North Dakota SIP for Regional Haze at 185.

NDDH has not adequately met the regional haze requirements of developing a long term strategy to show how it would meet reasonable progress goals to attain natural visibility conditions by 2064, as required by 40 C.F.R. §51.308(d)(1) and (d)(3). First, NDDH should not have limited its analysis of additional measures to provide for reasonable progress to facilities not already controlled by BART. As shown above, NDDH's proposed BART emission limits and requirements do not reflect the maximum emission reductions that could be achieved at the State's EGUs. For those controls or more stringent control efficiencies that NDDH determines are not required to meet BART, NDDH must still evaluate use of those control technologies and/or methods as part of its long term strategy to meet reasonable progress goals. For example, if NDDH determined SCR is not BART for an EGU, it could still require SCR at that EGU to meet reasonable progress requirements. Further, NDDH also excluded the Heskett EGU from evaluation of long term strategy requirements. While NDDH postponed a determination of whether Heskett was subject to BART, that should not exclude the unit from evaluation of pollution controls as part of the State's long term strategy.

Second, in evaluating additional control measures to meet the national visibility goal, NDDH should not just place emphasis on the benefit to visibility achieved by the reductions at each emissions unit. Instead, NDDH should evaluate the cumulative effective of the State's strategy to meet reasonable progress goals to attain natural visibility conditions by 2064. 40 C.F.R. §51.308(d)(3)(iv)(G).

Further, 40 C.F.R. §51.302(d)(3)(ii) provides:

> Where other States cause or contribute to impairment in a mandatory Class I Federal area, *the State must demonstrate that it has included in its implementation plan all measures necessary to obtain its share of the emission reductions needed to meet the progress goal for the area.*

[Emphasis added.]

Thus, NDDH must evaluate all available measure to reduce North Dakota's share of visibility impairing pollution as part of its long term strategy. Such available measures include emission reduction programs, imposition of emission limitations, and source retirement and replacements.

NDDH did not evaluate the potential for any EGU retirements in its draft regional haze SIP. Given the age of the State's coal-fired EGUs along with the fact that North Dakota's draft SIP falls far short of meeting reasonable progress goals for regional haze, NDDH must consider EGU retirements to meet reasonable progress goals as part of its long term strategy.

For the sources for which NDDH did evaluate controls, it did not evaluate the most stringent levels of control achievable. For example, for Antelope Valley Units 1 and 2, NDDH only evaluated a wet scrubber that could achieve 95% SO_2 removal even though, as we have shown above, wet scrubbers can achieve 98-99% SO_2 removal. Further, NDDH did not conduct any modeling to show the visibility improvement from use of a wet scrubber at the Antelope Valley units because it found the costs to be too high. As shown in the National Park Service SO_2 BART Summary spreadsheet (Ex. 11), the costs of wet scrubbers at Antelope Valley Units 1 and 2 ($5,899-$6,780/ton) are not out of the range of SO_2 BART control costs. A new wet scrubber at the Coyote Station is quite cost effective at $2,593/ton.

Even if the costs were more than previously required as BART, that should not be a reason alone to discount use of a control technology. This is especially true with North Dakota's regional haze SIP which fails to meet the uniform rate of progress necessary to attain natural visibility conditions by 2064. Further, given the fact that North Dakota sources cause and contribute to visibility impairment in other states, it is imperative that NDDH include all emission reduction measures in its long term strategy to meet reasonable progress goals. While it is true there will be costs to reducing visibility impairing pollution from North Dakota sources, such costs do not allow North Dakota to ignore the national visibility goal of the Clean Air Act and the requirements for regional haze SIPs. Thus, cost of controls alone should not be a determining factor in evaluating additional emission reduction options in the State's long term strategy. Accordingly, NDDH should evaluate the use of SCR at units such as Antelope Valley and Coyote, as well as at those EGUs for which NDDH determines SCR is not BART, for inclusion in its long term strategy.

In summary, North Dakota's draft SIP for regional haze fails to include adequate reasonable progress goals and fails to include an adequate long term strategy to meet reasonable progress goals. While North Dakota's proposed BART determinations will greatly reduce SO_2 emissions and, to a lesser extent, NO_x emissions from the State's BART-eligible EGUs, the State's plan does not go far enough to ensure that North Dakota's Class I areas and the Class I areas in other states that are impacted by North Dakota sources will achieve natural visibility conditions by 2064. Thus, North Dakota must adopt additional measures or requirements, including consideration of source retirements, as part of its long term strategy to achieve reasonable progress toward the national visibility goal.

III. North Dakota Must Also Propose Short Term Average Emission Limits on SO_2 Emissions in Order to Ensure Protection of the SO_2 Increments of the State's Class I Areas

The SO_2 emission reductions that North Dakota has proposed as BART for the State's BART-eligible EGUs should greatly help the State address the SO_2 increment violations that have been occurring at the North Dakota Class I areas.[48] And we recently learned that the State

---

[48] See 5/24/99 North Dakota Class I Area Calpuff Analysis; see also 5/8/03 EPA Dispersion Modeling Analysis.

has issued a draft plan for updating and evaluating a new modeling protocol and that the State plans on conducting a new periodic assessment of increment consumption in the near future.[49] However, in order for the State to be able to count on the SO_2 emission reductions proposed to meet BART in its new periodic assessment of SO_2 increment consumption or in other increment modeling analyses (such as those conducted for PSD permits), NDDH must propose for public comment short term average emission limits in addition to the 30-day average BART emission limits for the State's EGUs that are installing pollution controls. A long term average limit does not ensure 3-hour average or 24-hour average emissions will be reduced to the same levels, especially given that NDDH's proposed SO_2 BART limits are based on worst case sulfur content assumptions that are not reflective of the coal the units are currently burning.

The visibility protection program falls under the same part of the Clean Air Act that the increments do – that is, the prevention of significant deterioration program of Part C of the Clean Air Act. One of the mandates of the prevention of significant deterioration program is to preserve, protect, and enhance the air quality in national parks and wilderness Class I areas. CAA §160(2). For Class I areas, the Clean Air Act provides protection for Class I areas by requiring compliance with stringent PSD increments *and* by requiring protection of air quality related values including visibility. CAA §§162, 165(d), and 169A.

Because air quality modeling analyses that comply with EPA policies for increment consumption have shown that violations of the 3-hour and 24-hour average SO_2 increment are occurring in the State's Class I areas, it is imperative that North Dakota harmonize the SO_2 emission reductions that the State is requiring as part of its regional haze SIP with the requirement for the State's Class I areas to comply with the 3-hour and 24-hour average SO_2 increments. Thus, North Dakota must impose short term average SO_2 emission limits reflective of the SO_2 controls and emission reductions being required in its draft regional haze plan (primarily through BART) in order to be able to rely on the emission reductions in analyses of compliance with the 3-hour and 24-hour average SO_2 Class I increments.

Such emission limits must be reflective of the capabilities of the SO_2 controls being installed, in order to be consistent with the general purpose of the North Dakota regulations to "state such requirements as shall be required to achieve and maintain the best air quality possible, consistent with the best available control technology… and to facilitate the enjoyment of the natural attractions of this state." ND Reg. 33-15-01-01. The definition of "best available control technology" under the State's PSD regulations is defined as an emission limitation "based on the maximum degree of reduction" of a pollutant that is achievable. ND Reg. 33-15-15-01.2 incorporating by reference 40 C.F.R. 52.21(b)(12). And "emission limitation" is defined under the Clean Air Act as a requirement established by a state or EPA which limits emissions "on a continuous basis." CAA §302(k). Thus, in establishing short term average emission limits that can be relied upon in analyses of compliance with the PSD increments, North Dakota must set limits consistent with the maximum degree of emission reductions that is achievable with the BART SO_2 controls and that reflect operation of the SO_2 controls on a continuous basis. Without such short term average emission limits, NDDH cannot rely on the planned SO_2

---

[49] As discussed in NDDH's "A Plan for Updating and Testing the North Dakota Department of Health's CALMET and CALPUFF Protocol," Draft Final, December 29, 2009, available at http://www.ndhealth.gov/AQ/NoticesPSDStatusIncrementConsumption.htm.

reductions at the State's EGUs in any increment analyses until the BART controls have been installed and normal operation has resumed for at least two years.

As we stated above, we understand from the NDDH's draft plan to revise the State's modeling protocol that the State plans to conduct a new periodic assessment of SO_2 increment consumption soon. Not only is such an analysis required under 40 C.F.R. §51.166(a)(4), but a new analysis is also required because, in its previous assessment of increment consumption, NDDH relied on techniques and methods that are inconsistent with EPA policy and the intent of the Clean Air Act. Although EPA proposed revisions to its regulations that would have allowed for many of North Dakota's increment modeling techniques and approaches[50], EPA never finalized that rulemaking and has indicated it will not finalize that rulemaking. Therefore, North Dakota cannot rely on those techniques and approaches that are inconsistent with EPA policy and with the intent of the PSD program of the Clean Air Act in evaluating increment consumption. Because prior analyses by NDDH (in 1999) and by EPA (in 2003) that more closely complied with EPA policy showed numerous violations of the 3-hour and 24-hour SO_2 increments in the State's Class I areas, it is imperative that NDDH conduct a new assessment of SO_2 increment consumption following EPA policy and consistent with the PSD mandates of the Clean Air Act. And, for NDDH to rely on the BART SO_2 reductions in such an analysis, the State must propose and adopt short term average emission limits.

IV. Other General Comments

1. The proposed RH SIP notes that the visibility monitor (IMPROVE THRO1 monitor) is located at the Painted Canyon Overlook in the South Unit of Theodore Roosevelt National Park. It also notes that this one monitor is "representative" of haze conditions in the separate North Unit and the separate Elkhorn Ranch Unit of the THRO Park. However, why and how a single monitor can be or is representative of haze conditions at these other, distant locations is never discussed. We believe that without technical support, the assumption that THRO1 is representative of conditions elsewhere in the THRO are unsupported. It is not enough to simply assert that this one monitor is representative, without basis (see page 31 of the proposed RH SIP). To the extent that the RH SIP relies on this TR-North Unit and TR-Elkhorn Ranch Unit. This is a fundamental flaw of the analysis.[51]

2. The RH SIP does not provide the details of its calculations for baseline visibility including all input assumptions. Thus, the values used cannot be verified. This is especially important since the values used are greater than EPA recommended values.

3. The proposed SIP (page 68) notes that "The FLMs and EPA have expressed concerns about the modeling that was conducted. MDU has agreed to remodel using a revised

---

[50] 72 Fed.Reg. 31372, June 6, 2007.

[51] This critique is not in conflict with our support for treating THRO as it was designated: one mandatory Class I area, not three. In this case, THRO is one Class I area spread out over significant distance, and multiple monitors are appropriate in the same way that they would be for one large contiguous Class I area (e.g. Yellowstone National Park).

> modeling protocol. The Department will reassess the determination to exclude Heskett Station Unit 2 following review of the revised modeling. Heskett Unit 2 will be addressed in a supplement to this SIP revision." This analysis cannot be put off to the future and must be part of the regional haze plan. Without this analysis, the SIP is incomplete. In the alternate, if the Heskett analysis is not now included, the supplement should be subject to full public review.

Thank you for the opportunity to comment on the draft Regional Haze State Implementation Plan.

Sincerely,

Stephanie Kodish

EPA Responses to Public Comments on the Proposed Prevention of Significant Deterioration Permit for the Desert Rock Energy Facility

US Environmental Protection Agency Region 9

July 31, 2008

c. **Comment:** Further, 98% is not the highest achievable SO_2 control efficiency for low sulfur coal similar to Navajo's coal. The

Application and AAQIR rely on other permitted sources, corrupting the BACT process. Many other sources of information, other than just permitted levels, must be consulted to determine BACT...The top control option is a wet FGD designed to achieve 99%+ SO_2 control. This level of control has been achieved at the Mitchell Station in Pennsylvania using magnesium enhanced lime, a type of wet FGD...It has also been achieved at several coal-fired power plants in Japan and is proposed for several U.S. coal fired power plants.

Chiyoda's bubbling jet reactor (a type of wet FGD) has consistently achieved >99% SO_2 removal during long-term operation at the Shinko-Kobe power plant in Japan. This facility consists of two 700-MW coal-fired utility boilers. The wet FGD was designed to achieve 0.014 lb SO_2/MMBtu (9 ppmv at 3% oxygen) on an instantaneous basis and has consistently exceeded this level while treating gases with inlet SO_2 concentrations within the range proposed for DREF (1.78 lb SO_2/MMBtu compared to 1.84 lb SO_2/MMBtu for DREF). This technology has been guaranteed by Chiyoda to achieve 99% SO_2 removal on three coal-fired boilers in Japan. It also has been demonstrated in the U.S. at the University of Illinois's Abbott power plant and Georgia Power's Plant Yates and recently was licensed for use on several additional plants in the US, including Plant Bowen in Georgia, Dayton Power & Light's Killen and Stuart plants, and AEP's Big Sandy Unit 2, Conesville Unit 4, Cardinal Units 1 and 2, and Kyger Creek, among others. Black & Veatch and Southern Company are both U.S. licensees.

Mitsubishi, a vendor of scrubber systems, reports it has guaranteed SO_2 removal efficiencies up to 99.8 percent, including four coal-fired boilers.

Finally, a recent Lake Michigan Air Directors Consortium ("LADCO") and the Midwest Regional Planning Organization ("MRPO") presentation indicated that advanced FGD technologies could achieve 99.5% control for $1,240 to $2,875 per ton of SO_2 removed and wet FGD could achieve 99% SO_2 control for $1,881 to $3,440 per ton of SO_2 removed. [23]

Response: With respect to the claims that EPA's and the Applicant's reliance on other permitted sources has corrupted the BACT process and that higher levels of control have been achieved at other sources, the commenters are first referred to the responses to comments II.C.1.e and II.C.1.g. A BACT determination involves judgment and balancing, and does not involve simply picking the lowest numerical emission limit or the highest observed control efficiency. The design of wet a FGD system and the resulting control efficiency depends on a variety of parameters, including the characteristics of the fuel, boiler operating data and tolerances, emission requirements (not only for SO_2 but also for particulate, dust, temperature, and waste water), limestone availability and quality, and economic factors.[3] As discussed in the permit application, a comparison of relative control efficiencies of add-on SO_2 control equipment must take into account the amount of uncontrolled SO_2 to be treated. For example, for a given heat input, a facility with a BACT limit of 0.06 lb/MMBtu that achieves 95% control will result in fewer emissions to the atmosphere than a facility with a limit of 0.1 lb/MMBtu that achieves 98% control. It is therefore misleading for the commenters to cite to other facilities that achieve greater control efficiencies than proposed for the DREF while ignoring differences in site specific factors.

Moving to the commenters' specific claims, the commenters first assert that the Mitchell Power Station in Courtney, PA has achieved greater than 99% SO_2 control. In support of the statement, the commenters submitted data which purportedly represents daily emissions from the facility.[4] The commenters' assertion is misleading because the information submitted contains only 88 days worth of monitoring data collected over a span of 17 months between July 1983 and December 1984. As previously discussed, the EAB has recognized the distinction between measured emissions data at one point in time and an emissions limitation placed into a PSD permit which must be met continuously for the entire life of the facility. Actual emissions data reported by the facility pursuant to the Acid Rain program reveal that the emissions are much higher in recent years than they were for the brief period from 1983-1984. The following statistics reflect actual SO_2 emissions from the Mitchell Power Station in 2006:[5]

Total Number of Days Monitored:	312
Lowest Daily Average Emission Rate:	0.01 lb/MMBtu
Highest Daily Average Emission Rate:	0.36 lb/MMBtu
Frequency Analysis	
Range	**Number of Days**
$X \leq 0.06$ lb/MMBtu	29

---

[3] See *Alstom Environmental Control Systems Wet FGD Design Criteria*, included as Attachment 2.

[4] The data submitted by the commenters is on plain paper with no markings or other indications whatsoever that it represents the actual emissions from this facility. However, for the sake of the comment, EPA will consider the data to be legitimate.

[5] The facility had several startups, shutdowns, and process upsets in 2006. Emissions data from these periods were generally higher than for normal operations and were excluded from the statistical review. The raw data from EPA's Clean Air Markets database is included in Attachment 3.

0.07 lb/MMBtu $\leq X \leq$ 0.09 lb/MMBtu	125
0.10 lb/MMBtu $\leq X \leq$ 0.19 lb/MMBtu	138
0.20 lb/MMBtu $\leq X \leq$ 0.29 lb/MMBtu	16
0.30 lb/MMBtu $\leq X \leq$ 0.39 lb/MMBtu	4

It is clear from this data that the Mitchell Power Station has achieved a daily average emission rate equal to or less than the limit proposed for the DREF for only 29 days out of the year. The actual emissions were moderately higher for the remainder of the year. By comparison, the DREF would never be allowed to exceed 0.060 lb/MMBtu over a 24-hour average and would thus perform far better than the Mitchell Power Station on a heat input basis. Thus EPA does not agree with the commenters that the Mitchell Power Station provides evidence that the proposed DREF limit is not BACT.

The commenters' next claim that the Chiyoda's bubbling jet reactor has consistently achieved greater than 99% SO_2 removal during long-term operation at the Shinko-Kobe power plant in Japan and that it has been guaranteed by Chiyoda to achieve 99% SO_2 removal on three coal-fired boilers in Japan. In support of its claim regarding the three boilers in Japan, the commenters referred to a website operated by Burmeister & Wain Energy, which has the license for the CT-121 FGD process on the European market. This site contains two promotional documents. The first document, *CT-121 FGD Process* (included as Attachment 4), contains an elementary description of the CT-121 process and its purported advantages, including a generic statement that removal efficiencies up to 99%+ are possible. It does not, however, provide any technical information regarding the conditions under which such efficiencies can be achieved nor does it provide any information about actual guaranteed emission rates (see earlier discussion regarding comparison of control efficiencies versus actual emission rates). The second document, *Flue Gas Desulphurization Reference list CT-121*(included as Attachment 5), is simply a list of facilities in which the CT-121 process has been or will be installed, the installation dates, and the SO_2 control efficiencies, which range from 82% to 99%. This list clearly shows that this technology has a wide range of efficiencies and as with the first document, it provides no information about the conditions under which the higher efficiencies can be achieved nor does it state what the guaranteed emission rates are for the facilities that are achieving high removal efficiencies. It is also worth noting that many of the facilities in the list with higher control efficiencies are not in operation as the dates provided in the table are 2008 and beyond. The lack of any useful technical information in these documents provides EPA with no basis for a more detailed response. The commenters did cite to one technical paper by Yasuhiko Shimogama and others. Though this paper indicates that 99% control is being achieved at the Shinko-Kobe plant, EPA can not rely on this document alone to establish BACT. Other pertinent information such as the permitted emission limits, averaging periods, and actual emissions data should be submitted. It is the commenters' burden to provide that information and the commenters have failed to meet that burden in this case. Nonetheless, EPA attempted to contact the Japan Ministry of the Environment for additional information but to date, our request for information has not been answered. EPA did, however, receive a response to a request for information from Kobe Steel, Ltd., the company that owns and operates the Shinko-Kobe plant. Specifically, EPA asked about Kobe Steel's general experience using the technology. In his reply, the manager of the Power Plant Technology Section stated that the SO_2 removal efficiency has never dropped below the guaranteed performance level, that their experience with the CT-121 process has been positive, and that their decision to use the CT-121 at that plant was the correct one. However, they also noted that they have been experiencing problems with the system's sulfur gas fan. Specifically, they have been experiencing degradation of fan efficiency by gypsum deposits during normal operation of the plant. They stated that an attempt has been made to remedy the problem by installing a washing system but that has not been sufficient and the problem still remains unresolved by the supplier. As a result, they are required to conduct periodic preventive maintenance every two to three months. During a planned outage over a weekend, they stop plant operations for two days and wash the fan blades. See Attachment 6, *July 31, 2007 e-mail from Gary Tsuchida*. EPA does not believe it is reasonable to require the use of a technology with unresolved operational issues that require such frequent shutdowns of the plant. Thus while the technology appears promising for certain situations, it may not be suitable for all situations and EPA cannot simply require its use in every instance. As the commenters later note in their comments, this technology is being planned for use at other plants. Those installations will likely provide additional data and operating experience that does not currently exist but that is needed to fully evaluate this technology in future BACT analyses.

The commenters also claim that Chiyoda's bubbling jet reactor has been demonstrated in the U.S. at the University of Illinois's Abbott power plant and Georgia Power's Plant Yates and recently was licensed for use on several additional plants in the US, including Plant Bowen in Georgia, Dayton Power & Light's Killen and Stuart plants, and AEP's Big Sandy Unit 2, Conesville Unit 4, Cardinal Units 1 and 2, and Kyger Creek.

The commenters are correct that the Chiyoda's CT-121 FGD system is used at the University of Illinois's Abbott Power Plant and Georgia Power's Plant Yates. However, a review of the actual emissions data from these facilities again demonstrates that the DREF would have lower emissions than these facilities on a heat input basis. The following statistics reflect actual SO_2 emissions data from Plant Yates in 2006. The raw data from the Clean Air Markets database is included in Attachment 7

Total Number of Days Monitored:	346
Lowest Daily Average Emission Rate:	0.02 lb/MMBtu
Highest Daily Average Emission Rate:	0.38 lb/MMBtu
Frequency Analysis	
Range	**Number of Days**
$X \leq 0.06$ lb/MMBtu	48
0.07 lb/MMBtu $\leq X \leq$ 0.09 lb/MMBtu	28
0.10 lb/MMBtu $\leq X \leq$ 0.19 lb/MMBtu	140
0.20 lb/MMBtu $\leq X \leq$ 0.29 lb/MMBtu	97
0.30 lb/MMBtu $\leq X \leq$ 0.39 lb/MMBtu	33

It is again clear from this data that while Plant Yates has achieved a daily average emission rate equal to or less than the limit proposed for the DREF for short periods of time, for the majority of the time the emission rates were significantly higher. Furthermore, information obtained from the Illinois Environmental Protection Agency (IEPA) shows that the actual measured control efficiency of the FGD system at the Abbott Power Plant is 92.3%. See Attachment 8, *6/14/2007 fax from Joe Kotas*, IEPA. In addition, the Abbott Power Plant includes three boilers of approximately 200 MW each. To the extent that boiler characteristics affect emissions and control technology design, these units do not serve as a good reference for the DREF, which has much larger units. EPA thus disagrees with the commenters that the use of Chiyoda's equipment at another facility is an indication the proposed limit for the DREF is not BACT.

The commenters are also correct that Chiyoda's FGD system is being installed on several other plants. However, most of those referred to by the commenters are not yet constructed or operating. According to the Kentucky Department for Environmental Protection, Division for Air Quality, the Big Sandy project has been postponed until 2014; it is thus not useful for establishing BACT for the DREF. See Attachment 9, *e-mail from Candy Montgomery, Kentucky DAQ*, June 8, 2007. The Conesville, Cardinal and Kyger

Creek projects are proceeding but are currently in various stages of construction. According to the Ohio EPA, the control efficiency for these systems is estimated at 98%. However, even with 98% control, the emission limits (in terms of lb/MMBtu heat input) for these facilities will be significantly higher than the proposed limit for the DREF, further supporting EPA's conclusion that the DREF limit represents BACT. The current status of these facilities and their emission limits are summarized in the following table:

Facility/Unit	**Stage of Construction**	**Emission Limit**
AEP Conesville #4	Early stage of construction	0.90 lb/MMBtu (30-day rolling average)
AEP Muskingum River #5	Construction halted	1.5 lb/MMBtu (30-day rolling average)
AEP Kyger Creek Units 1-5	Early stages of construction	1.20 lb/MMBtu (30-day rolling average)
AEP Cardinal Units 1&2	Construction nearing completion	2.5 lb/MMBtu (30-day rolling average)

See Attachment 10, *e-mail from Dean Ponchak*, Ohio EPA, June 8, 2007. The emission limits for Dayton Power & Light's Killen and Stuart plants are similarly higher than the DREF limit:

Facility/Unit	**Emission Limit**
Killen Station #2	1.2 lb/MMBtu
Stuart Unit #4	1.77 lb/MMBtu (30-day average)
Stuart Unit #3	1.77 lb/MMBtu (30-day average)
Stuart Unit #1	1.77 lb/MMBtu (30-day average)
Stuart Unit #2	1.77 lb/MMBtu (30-day average)

See Attachment 11, *e-mail from Cindy Charles*, Ohio EPA, June 8, 2007. FGD systems on Units 1-4 at Plant Bowen are also in the construction phase. However, these systems are being installed for purposes of compliance with the Clean Air Interstate Rule and at the time this document was written the facility has not yet received its allocation. Until the allocations are received, the permits to install these systems have no emission limits or other operating requirements.

The commenters further claim that Mitsubishi reports it has guaranteed SO_2 removal efficiencies up to 99.8 percent, including four coal-fired boilers. The commenters are again misleading in their statements because they point to control efficiencies without respect to inlet pollutant loading. In support of their statements, the commenters refer to two technical papers and a page on Mitsubishi Heavy Industries' website. Both technical papers explicitly state that the highest SO_2 control efficiencies are associated with high inlet SO_2 concentrations:

> In this paper, performance test data for the latest single-tower coal-fired application (a 600MW module) that started commercial operation on July 12, 2004 are reported. In addition, **super high SO_2 removal efficiency (99-99.9%) <u>under high inlet SO_2 conditions</u>** (2,000-3,000ppm) achieved by a single DCFS module and an extraordinary space-saving design related to its compactness feature are also introduced here...
>
> Nakayama et. al. at 1 (emphasis added).

> The twin tower design, which is the combination of co- and counter-current designs, is selected when both high particulate removal and **extremely high desulfurization performance requirement (98% and over) <u>for high sulfur coal</u>** are required...In the past 2 or 3 years, we have been successful in achieving **ultra-high SO_2 removal efficiency (e.g., 99.9%) <u>with a high inlet SO_2</u>** using a single tower DCFS.
>
> Nakayama et. al. at 2 (emphasis added).

> This paper provides a detailed description of the DCFS FGD system including operating data from recent installations...Recent operating experience is reviewed in detail. In particular, the paper highlights design requirements to achieve **SO_2 removal efficiencies as high as 99.9 percent <u>on high sulfur coals</u>**.
>
> Klingspor et. al. at 1 (emphasis added).

High inlet concentrations tend to make high removal efficiencies more practical and economical. Also, as previously discussed, having the lowest emission rate on a heat input basis does not necessarily require achieving the highest control efficiency if the use of low-sulfur coal results in lower uncontrolled emissions to begin with. EPA thus remains convinced that the proposed limit represents BACT in this instance.

Finally, the commenters note that a recent Lake Michigan Air Directors Consortium (LADCO) and Midwest Regional Planning Organization (MRPO) presentation indicated that advanced FGD technologies could achieve 99.5% control for \$1,240 to \$2,875 per ton of SO_2 removed and wet FGD could achieve 99% SO_2 control for \$1,881 to \$3,440 per ton of SO_2 removed. According to the engineering analysis for boilers referenced in the presentation, the cost estimates referred to by the commenters were developed assuming a fuel sulfur content of 2.5%. This is 2-3 times higher than the sulfur content of the coal to be used at the DREF and thus the LADCO example does not necessarily reflect the true economics for this or other facilities that use low sulfur coal. Furthermore, the LADCO report cautions that these estimates are intended to provide a general indication of the technical and economic feasibility of each control technology and that a unit-specific evaluation must still be performed. The report further recognizes the likelihood that site-specific vendor quotes will be required to get accurate cost analysis results. See Attachment 12, *LADCO Report* at 20.

d. **Comment:** Japan regulates SO_2 emissions to about 10 ppm (0.02 lb/MMBtu) from new industrial facilities locating in polluted areas. There are currently two Japanese vendors who supply wet FGD systems in the U.S. market that are able to achieve 99% SO_2 control on low sulfur coals. These are Chiyoda and Mitsubishi, as discussed supra. These two wet FGD systems are more cost effective, require less water and electricity, generate less wastes, and remove more mercury and particulate matter than the type of wet FGD selected for DREF. They do not have any adverse energy, environmental, or economic impacts.

This Japanese experience is supported by two facilities in the U.S. The U.S. EPA issued a PSD permit to AES Puerto Rico to construct and operate a 454-MW coal-fired CFB project. The permit requires the unit to meet an SO_2 limit of 0.022 lb/MMBtu or 9.00 ppmvd corrected to 7% oxygen on a 3-hour basis, compared to 0.09lb/MMBtu on a 3-hour basis and 0.06 lb/MMBtu on a 24-hour basis for DREF. The much lower AES Puerto Rico limit has been achieved. Further, Utah issued a permit for the Nevco Sevier project in October 2004. Its SO_2 limits are: 0.022 lb/MMBtu based on a 30-day average and 0.05 lb/MMBtu based on a 24-hour average. We are not advocating CFBs for DREF, but rather that the emission limits proposed for these CFB units should be included in the top down BACT analysis for PC boilers, as set out below. [23]

ADVATECH™

A company of URS and MHIA
