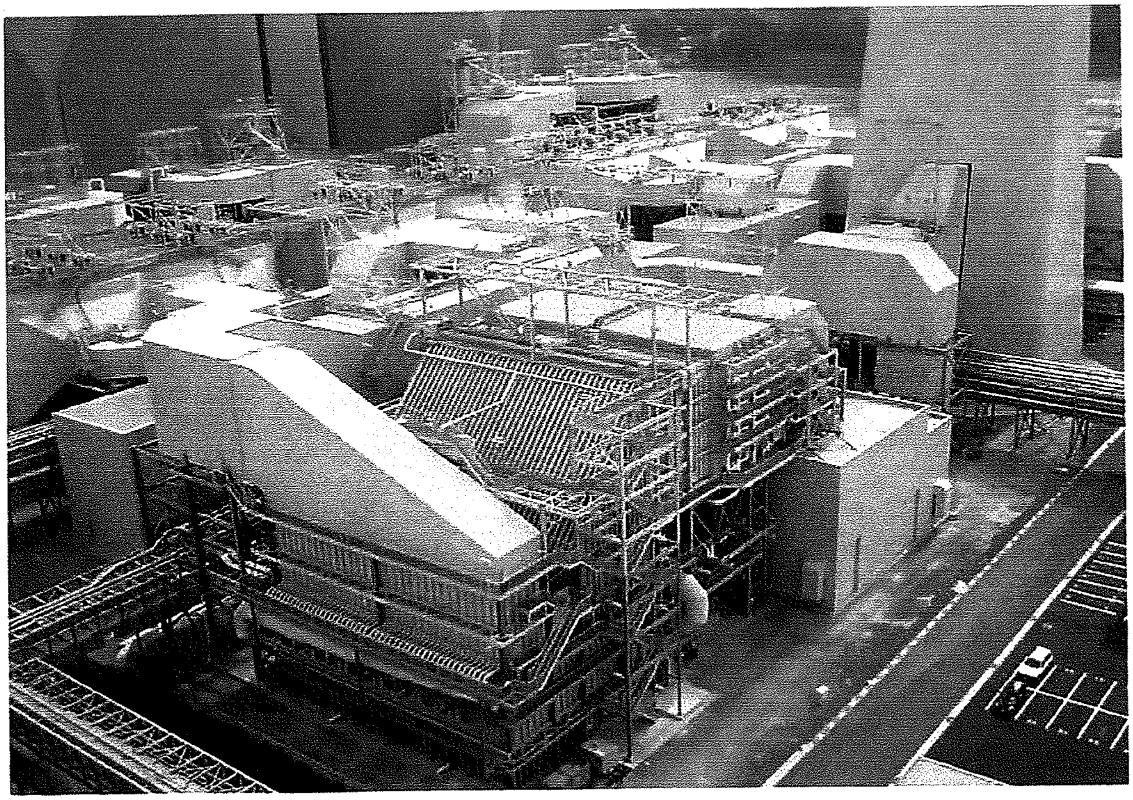
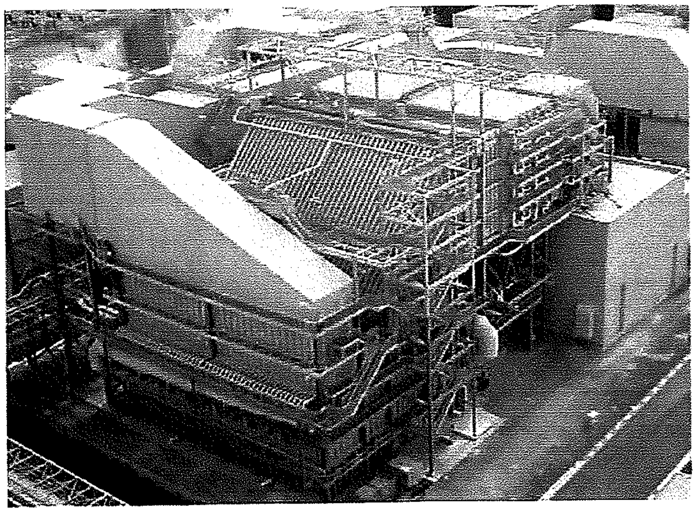
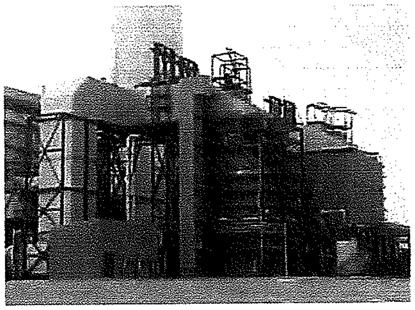
Advanced Flue Gas Desulfurization



The Next Generation



The EPDC Tachibanawan Power Station has a single 1,050 MWe DCFS module that is the largest FGD module in the world. The unit has operated at 100 percent availability since startup in 2000. The SO_2 removal is in excess of 95 percent and can be tuned for greater removal by optimizing recycle pump operation.



The twin tower DCFS FGD system installed at the Rathaburi Power Station in Thailand operates at 97 percent SO_2 removal efficiency.

The plant is designed with close-coupled gas-to-gas regenerative reheat located on top of the absorber.

Unrivaled Experience

Highlights of Our Worldwide FGD Experience

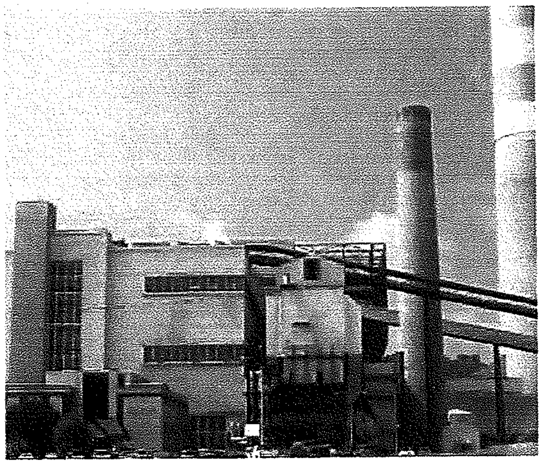
Installed FGD Capacity	~56,000 MWe
FGD Orders Last 10 Years	~30,000 MWe
Highest SO_2 Guaranteed Removal	99.80%
Highest SO_2 Removal w/o Additives	99.90%
Highest SO_2 Concentration	7,800 ppm
Largest Single Absorber	1,060 MWe
Longest Time Between Outages	2 yrs
Spare Modules Installed	None
Highest Availability, Single Module	100% / 12yrs

Advatech was formed jointly by URS and Mitsubishi Heavy Industries America (MHIA) to provide flue gas desulfurization (FGD) systems to American utilities. Advatech combines the Mitsubishi Heavy Industries (MHI) Double Contact Flow Scrubber (DCFS) advanced FGD technology and the comprehensive engineering, procurement, and project implementation services of URS.

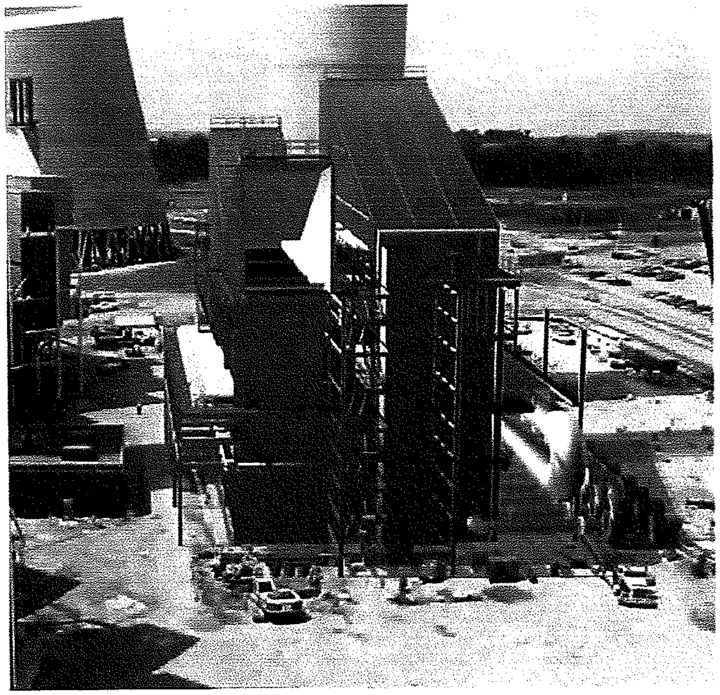
Through Advatech, URS and MHIA bring unsurpassed technology, engineering, design, procurement and project implementation services backed by strong parent companies. Radian Corporation, now a part of URS, began offering FGD services over 30 years ago.

The first MHI FGD system was installed in 1964. Today, MHI is the world's leading supplier of FGD systems with over 56,000 MWe installed on more than 160 boilers in 14 countries.

Available in the US through Advatech, the DCFS system is highly reliable, and the uniqueness of its design allows it to operate at 100 percent availability with no spare



Advatech is currently designing a single-module DCFS FGD system for Alabama Power's 1,151 MWe Plant Gorgas which will achieve 98 percent SO_2 removal efficiency with ultra-high reliability.



The twin-tower DCFS FGD system currently being installed at the Paradise Power Station will be the largest single-module FGD system in the world. The system is designed to achieve 98 percent SO_2 removal burning 3.5 percent sulfur coal and will produce wallboard-quality gypsum. The unit is slated for commercial operation in 2006.

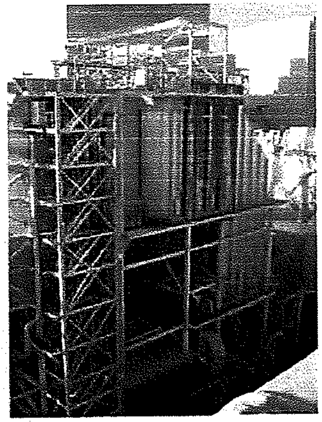
module required. SO_2 removal efficiencies as high as 99.8 percent have been guaranteed and achieved on a 3 percent sulfur fuel while producing wallboard-grade gypsum.

The DCFS FGD system is particularly robust, can tolerate dramatic changes in operating conditions, and is designed to operate two to four years between scheduled outages.

All Advatech's limestone-based FGD systems produce a gypsum byproduct. The majority of these installations sell their gypsum to either wallboard or cement plants.

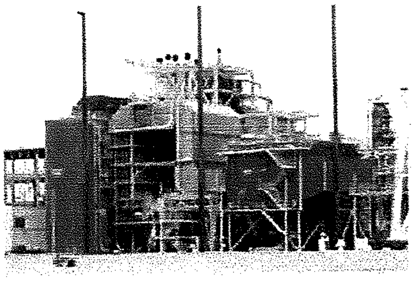
FGD Projects in the U.S.

NiSource Bailly (Pure Air)	530 MWe	95% SO_2 Removal
TVA Paradise	1,060 MWe	98% SO_2 Removal
TVA Widows Creek	500 MWe	96% SO_2 Removal
TVA Colbert	500 MWe	97-98% SO_2 Removal
TVA Bull Run	920 MWe	95-98% SO_2 Removal
Alabama Power Gorgas	1,151 MWe	98% SO_2 Removal



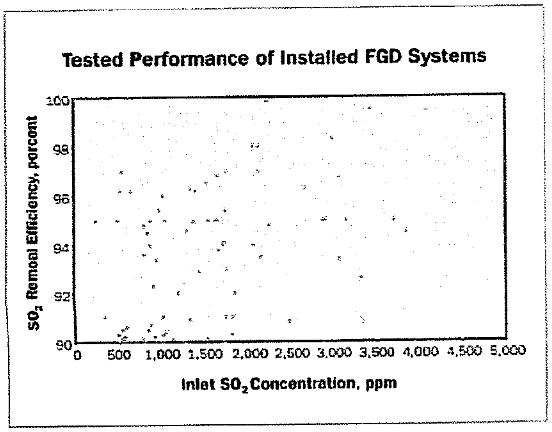
With over two years of continuous operation, this DCFS unit cleans flue gas at Hokkaido Electric's 700 MWe Tomatoazuma station.

Started in early 2002, the 600 MW Kansai Electric Gobo Power Station processes 1 percent sulfur with more than 99 percent SO_2 removal.



The twin tower DCFS FGD system installed at the KOA refinery operates at 99.9 percent SO_2 removal efficiency (without additives), with an inlet SO_2 at 2,100 ppm and less than 2 ppm in the stack. The system produces wallboard-grade gypsum, and has operated at 100 percent availability with four years between scheduled outages since its startup in 1995.

Multipollutant Control Capabilities



In addition to SO_2, the DCFS FGD system is capable of reducing emissions of particulates, acid mist and mercury. The DCFS design which provides the ability to achieve ultra-high (above 99 percent) removal efficiencies of SO_2 without additives is beneficial for the control of other pollutants. Particulate emissions can be reduced by up to 95 percent after locating a high efficiency ESP upstream of the FGD system, and by up to 99.6 percent without a particulate control device. In tandem with a reagent injection process to control acid mist emissions, opacity levels can be reduced to single digits. The DCFS FGD system is also efficient in removing oxidized mercury. In combination with a mercury oxidation

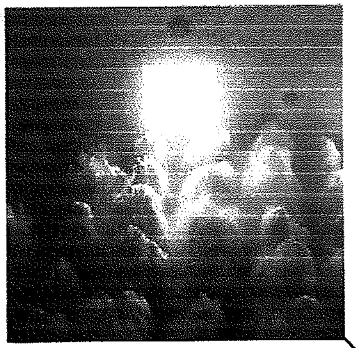
Advatech, through MHI, has extensive experience with FGD systems operating at 100 percent availability on low-and high-sulfur fuels.

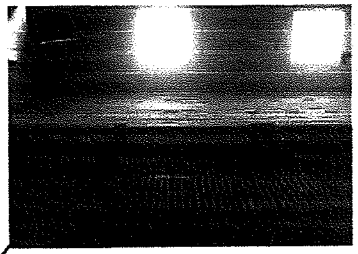
This table shows recent operating experience with DCFS FGD units for a wide range of boiler size, fuel sulfur content and SO_2 removal performance. In total, MHI has more than 160 FGD units worldwide including the world's largest.

catalyst, most of the elemental mercury can be captured as well. More importantly, the efficient forced oxidation systems incorporated in the DCFS design avoids reemitting of oxidized mercury. Advatech is working on providing oxidation catalysts for control of elemental mercury and current pilot plant tests show promising results.

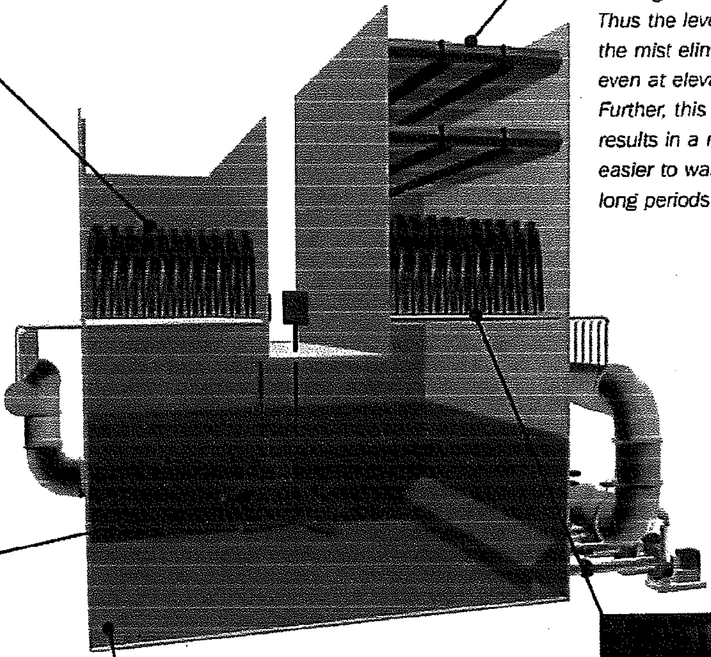
The Advatech DCFS Design

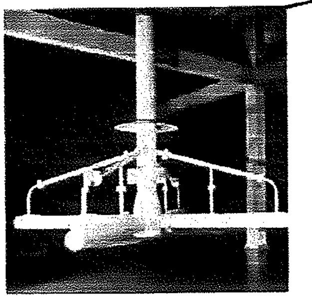


Multiple fountains provide for exceptional gas liquid contact ensuring SO_2 removal efficiencies of up to 99.9 percent! The gas is contacted twice as the liquid sprays upward and as it falls downward. This double contact provides a more efficient mass transfer and higher SO_2 removal per unit of L/G.

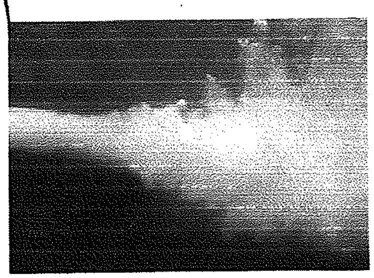


Use of the DCFS fountains for gas liquid contact minimizes the droplet loading on the mist eliminators. Thus the level of liquid loading to the mist eliminators is much less even at elevated gas velocities. Further, this lower liquid loading results in a mist eliminator which is easier to wash and keep clean for long periods between outages.

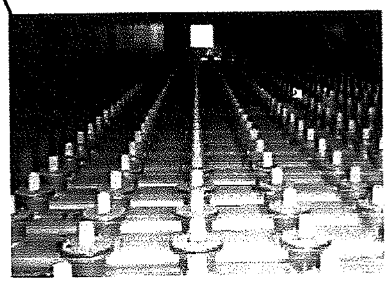




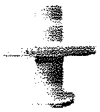
Powerful Air Rotary Sparger (ARS) provides excellent agitation simultaneously distributing fine bubbles used in complete oxidation of calcium sulfite to calcium sulfate. The patented ARS provides an ultra efficient use of oxidation air while ensuring that sufficient gypsum solids exist throughout the module thus minimizing any scaling potential.



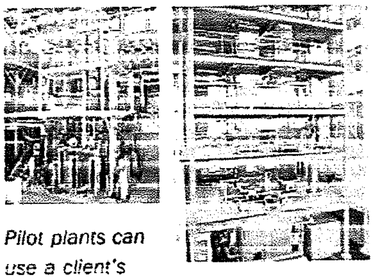
The patented Jet Air Sparger (JAS) was developed to provide oxidation air to the vessel using an eductor to pull atmospheric air (or compressor enhanced air) for oxidation of calcium sulfite to calcium sulfate. The JAS produces very fine air bubbles which enhance the mass transfer and minimize capital and operating costs.



The Advatech DCFS introduces the slurry in a single always-operating spray level. The single level eliminates header-to-header erosion and allows for operation of slurry solids concentration of 30 wt%. The higher solids concentration and the continuous operation ensure the tower stays exceptionally clean and scale free. All recycle pump motors and gear boxes are identical, with a spare recycle pump usually provided to ensure availability.

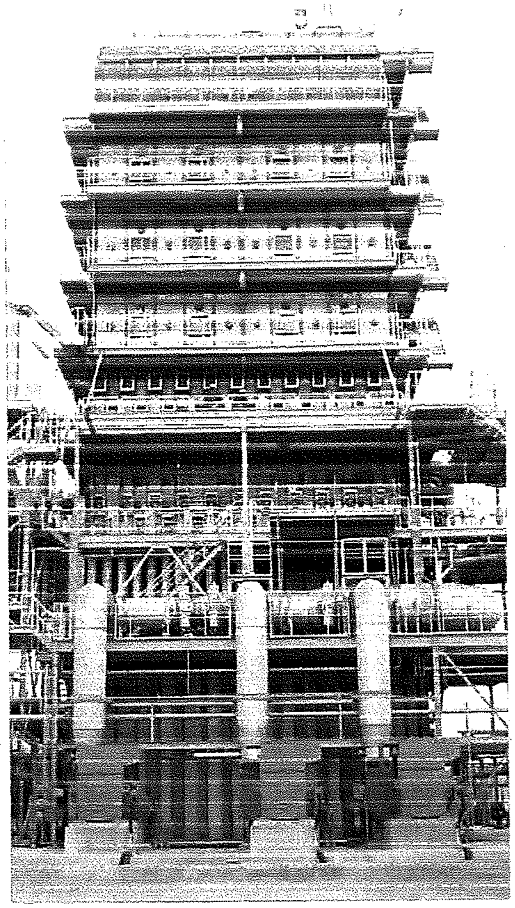


SIC spray nozzle



Pilot plants can use a client's coal, limestone and make-up water to simulate desired conditions.

100 MWe absorber fluid dynamics model



400 MW single-tower DCFS test facility used to improve the single tower design to achieve ultra-high removal capability

Relentless Improvement

Advatech, through MHI and URS, is strongly committed to research and development and to bringing continuous improvements to the utility industry. We have large modern research facilities dedicated to air pollution control.

Advatech's wet FGD system has evolved to a very simple, reliable and highly efficient single loop, double contact flow scrubber. During recent years, prominent technology improvements have included the single stage DCFS spray header design, air rotary sparger for combined slurry mixing and gypsum-oxidation, and jet air sparger for gypsum oxidation without use of oxidation compressors.

A full-featured wet FGD pilot plant which can use site-specific coal, limestone and water sources is available to model client-specific operating conditions.

Recent developments have focused on control of trace emissions such as sulfuric acid mist (SO_3) and mercury (Hg). URS has introduced a new process for control of SO_3 emissions by use of sodium by-sulfite injection. When injected upstream of the air preheater, the acid dew point is lowered sufficiently, which can result in a significant increase in boiler efficiency. Mercury control technologies are being studied vigorously by both URS and MHI, and technologies for control of mercury emissions will be introduced to the market in the near future.

Advatech brings the full talent and capabilities of MHI and URS research and development to the market. We design our control technologies to account for future emissions control requirements. Our technologies will help you bridge the gap to future emissions control legislation.

Corporate Strength

Advatech combines the strength of two world-class organizations—URS and Mitsubishi Heavy Industries America—to bring the best FGD systems to the United States. With Advatech, you get not only the DCFS technology, but also all the R&D, engineering and implementation experience, and the corporate commitment from both companies. Advatech is providing design and construction services to the Tennessee Valley Authority for up to five FGD systems. Advatech is now designing the first large FGD system for the Southern Company—at Alabama Power's Plant Gorgas.

Subject:	Re: Heskett Unit 2

Tom:

Based on our review of AECOM's December 17, 2009 "Updated BART Modeling Results for R.M. Heskett Station Unit 2," our preliminary conclusions are that an EPA-approved protocol was used, and the results indicate that Heskett Unit 2's impact was less than the subject-to-BART threshold of 0.5 deciviews. Therefore, it appears appropriate for the State to determine that the source is not subject to BART. However, the source may still qualify for potential emission reductions under the Reasonable Progress requirements of the Regional Haze Rule. In addition, please note that we can only reach a final decision regarding the modeling and its results, and any other aspect of the Regional Haze SIP, through our own notice and comment rulemaking.

Thanks for your follow-up on this one......Amy

Amy:

Will we be getting a letter from you indicating that EPA concurs that Heskett Unit 2 is not subject to BART? We would like to have it for our records.

General Comments

Comment 1: The Department received 30 nearly identical emails from various individuals. The emails asked the Department to require additional control on the power plants and more aggressively pursue identified emissions reductions from all sources of pollutants. This was also reiterated in two additional emails and the oral testimony by Jim Kambeitz.

Response: The Department has required all emissions reductions that are required by rule or law. The SIP will reduce SO_2 emissions from power plants by approximately 68% and nitrogen oxides emissions by approximately 39% (based on 2000-2004 average emission rate). Overall, sources in North Dakota will reduce total sulfur dioxide emissions by approximately 106,000 tons/yr (60%) and nitrogen oxides by 58,000 tons/yr (25%). The uniform rate of progress for this planning period would only require a 23.3% improvement in visibility. The Department believes the reductions that will be achieved represent North Dakota's fair share of emissions reductions for the planning period. None of the commenters provided any technical argument that the Department was not complying with the Clean Air Act or the rules promulgated thereunder. The Department stands by its decision.

Comment 2: Two email commenters suggested that the Department needed to require additional emissions reductions in order to protect public health.

Response: The Department has reviewed ambient monitoring data in the Beulah area which is the most heavily affected area by power plants and a coal gasification plant. Five ambient monitors are operated in the immediate area. In 2008, the maximum 3-hr SO_2 concentration was 39 ppb (7.8% of the NAAQS), the maximum 24-hour SO_2 concentration was 9 ppb (6.4% of the NAAQS), and the maximum annual average SO_2 concentration was 1.8 ppb (6% of the NAAQS). For NO_2, the maximum annual average concentration was 2.7 ppb (5.1% of the NAAQS). The NAAQS were established by EPA to protect public health and welfare, including young individuals, with an adequate margin of safety. The reduction in emissions from the power plants and the other sources should reduce these ambient concentrations. The Department believes the public health and welfare is protected and air quality only will improve with the proposed reductions in emissions.

Montana Dakota Utilities Comments

Comment 1: Montana Dakota Utilities (MDU): MDU recalculated the expected SO_2 reductions at Heskett Station Unit 2 from limestone injection into the boiler. They excluded 2002 from the calculation and calculated a 474 tons per year reduction.

Response: The Department has reevaluated its calculation of the expected reduction. To be consistent with calculations for other sources, 2002 data was not eliminated. Based on the reevaluation, the Department expects a 553 ton/yr reduction from the 2000-2004 average emission rate.

Comment 2: MDU wanted the latest BART applicability modeling analysis and EPA's approval of the modeling protocol included in the final SIP revision.

Response: These documents will be included in the final SIP revision.

Comment 3: MDU asked the Department to consider the amount of visibility improvement that could be achieved by adding controls to Heskett Unit 2 when determining the reasonable progress goals.

Response: The visibility improvement will be considered in the calculation of cost (i.e., dollar per deciview). The other three factors for determining reasonable progress will also be considered.

Department of Interior (DOI) Comments

The DOI comments took the form of a response to the Department's response to the DOI comments of October 23, 2009.

Comment 1: The DOI still contends that TRNP should be treated as one area for visibility modeling.

Response: The Department still believes that the three units of TRNP should be treated as three distinct areas. Our reasons are stated in our response to the October 23, 2009 comments. We stand by our comments.

Comment 2: Regenerative Selective Catalytic Reduction (RSCR) should be evaluated.

Response: As pointed out by the commenter, this type of system requires much more space than a conventional TESCR system. Both the M.R. Young Station and Leland Olds Station have limited space and could not accommodate RSCR. The commenter indicated that RSCR has a high capital cost when compared to conventional SCR. The Department rejected TESCR and LDSCR at all four stations due to an excessive cost and/or lack of significant improvement in visibility. This unit will not provide any improvement in visibility over conventional TESCR and LDSCR. No technical details were provided so that the Department could make a comparison; therefore, it is not considered BART.

Comment 3: Follow up to October 23, 2009 comment 6.

DOI suggested that the Department should explain how it considered the benefits of reducing emissions with respect to visibility improvements at multiple Class I areas.

Response: The Department provided visibility modeling results for LWA and the three units of TRNP. We looked at both the maximum improvement at each of the four areas; the average for each area and the average for all of the areas (see tables in each BART analysis). We believe we have complied with the Clean Air Act.

As pointed out previously, only the Coal Creek Station is subject to the BART Guideline (40 CFR 51, Appendix Y) and only for NO_x. EPA has stated that "… states are not required to follow these guidelines for EGUs located at power plants with a generating capacity of less than 750 MW" (FR Vol. 70, No. 128, 39131). Within the Guideline, EPA states "For sources other than 750 MW power plants, however, States retain the discretion to adopt approaches that differ from the guidelines" (Appendix Y to Part 61, Section I.H.). The NDDH has exercised this discretion when evaluating the various BART options.

Comment 4: Follow up to Comment 8 from October 23, 2009

DOI stated that they had commented to EPA Region 9 that they had underestimated the efficiency of SCR in the ANPR for the Four Corners Plant.

Response: The Department has reviewed the EPA Air Pollution Control Cost Manual which states "In practice, SCR systems operate at efficiencies in the range of 70% to 90%". EPA's Air Pollution Control Technology Fact sheet for selective catalytic reduction (EPA-452F-03-032) states "SCR is capable of NO_x reduction efficiencies in the range of 70% to 90%". The Oregon DEQ hired Eastern Research Group, Inc. (ERG) to review the BART analysis for the PGE Boardman Plant. In their review, ERG stated "With regard to the performance of existing low NO_x burners (LNB) with overfire air (OFA) and SCR, reductions of 70 to more than 90 percent have been documented from recent installations; however, these are based on units that operate mainly during the ozone season and that have substantial opportunity for off-season maintenance and catalyst cleaning. The impact of existing LNB with OFA and SCR of the Boardman Plant under year-round operation would need to be considered in selecting a permit level." The NDDH believes the use of 80% is a reasonable choice for a source that must meet a BART emission limit on a long-term continuous basis.

Comment 5: Follow up to Comment 9 from October 23, 2009

DOI indicated they had commented to EPA Region 9 that the cost of SCR had been overestimated.

Response: In addition to the EPA estimate for SCR at the Four Corners Power Plant, the Department also reviewed the analysis commissioned by the Oregon DEQ for the cost of SCR at the PGE Boardman Plant. The analysis, which was prepared by Eastern Research Group, Inc. (ERG) states, "Nonetheless, all of these sources do point to a rapid escalation in SCR installed costs since 2004. ERG analyzed the 2007 cost-basis data by eliminating the three highest and one project that was known to be very dissimilar to the Boardman Plant characteristics. The remaining nine projects range from \$207/kw to \$267/kw, with an average of \$227/kw. ERG believes that this is a reasonable representation of 2007 costs of large SCR installations under normal retrofit conditions." DOI's estimate of the Total Direct Capital costs for SCR was less than \$150/kw for all facilities and substantially less for most units (i.e. \$101/kw at Stanton Unit 1). The NDDH <u>continues</u> to believe DOI has severely underestimated the cost of SCR. Since high dust SCR is not technically feasible for North Dakota lignite; the DOI cost estimates are even more erroneous since they do not include a reheat system or reheat annual costs. Based on the above, we believed the EPA Control Cost Manual is inappropriate for estimating the cost of

SCR. The manual states in Section 2.4 that the costs for tail-end SCR cannot be estimated from this report because they are significantly higher than the high-dust SCR systems due to flue gas reheating requirements.

Comment 6: Follow up to comment 10 on October 23, 2009

DOI believes the NDDH is placing too much emphasis upon incremental differences in visibility improvement. NDDH should support their claim that single source modeling overpredicts the actual improvement by a factor of 5-7.

Response: The preamble to the BART Guideline states "Because each Class I area is unique, we believe states should have flexibility to assess visibility improvements due to BART controls by one or more methods, and we agree with commenter's suggestions to do so." (FR Vol. 70, No. 128, p.39129). The NDDH has looked at the difference in improvement for each control option. This is the same as looking at the total improvement for each control option and determining the difference in visibility improvement. Indirectly, the total improvement of each option is considered.

The difference between cumulative and BART single-source modeling results starts with the logarithmic relationship between deciview and light extinction, which is based on the proven concept that an observer will detect visibility changes more easily in clean air than in dirty air. Deciview is related to light extinction using the equation

$$dv = 10 \times \ln(b_{ext} / 10)$$

where

dv = deciview

b_{ext} = light extinction in units of inverse mega-meters (Mm^{-1})

In BART single-source modeling, the incremental impact of the subject source is based on a background of natural visibility conditions only. In cumulative modeling, as conducted by WRAP, the incremental impact of the subject source is based on a background of natural visibility conditions plus the impact of a complete inventory of all other source emissions which affect visibility. Therefore, calculated delta-deciview for the subject source for the cumulative case will be lower than for the single-source case.

A simple hypothetical example can illustrate the difference in single-source and cumulative visibility modeling. Assume that a subject source is contributing 5 Mm^{-1} to total light extinction and that the natural visibility background is 20 Mm^{-1}. Under single-source modeling, delta-deciview for the subject source would be calculated:

$$\text{delta-dv} = [10 \times \ln(25 / 10)] – [10 \times \ln(20 / 10)] = 9.16 – 6.93 = 2.23$$

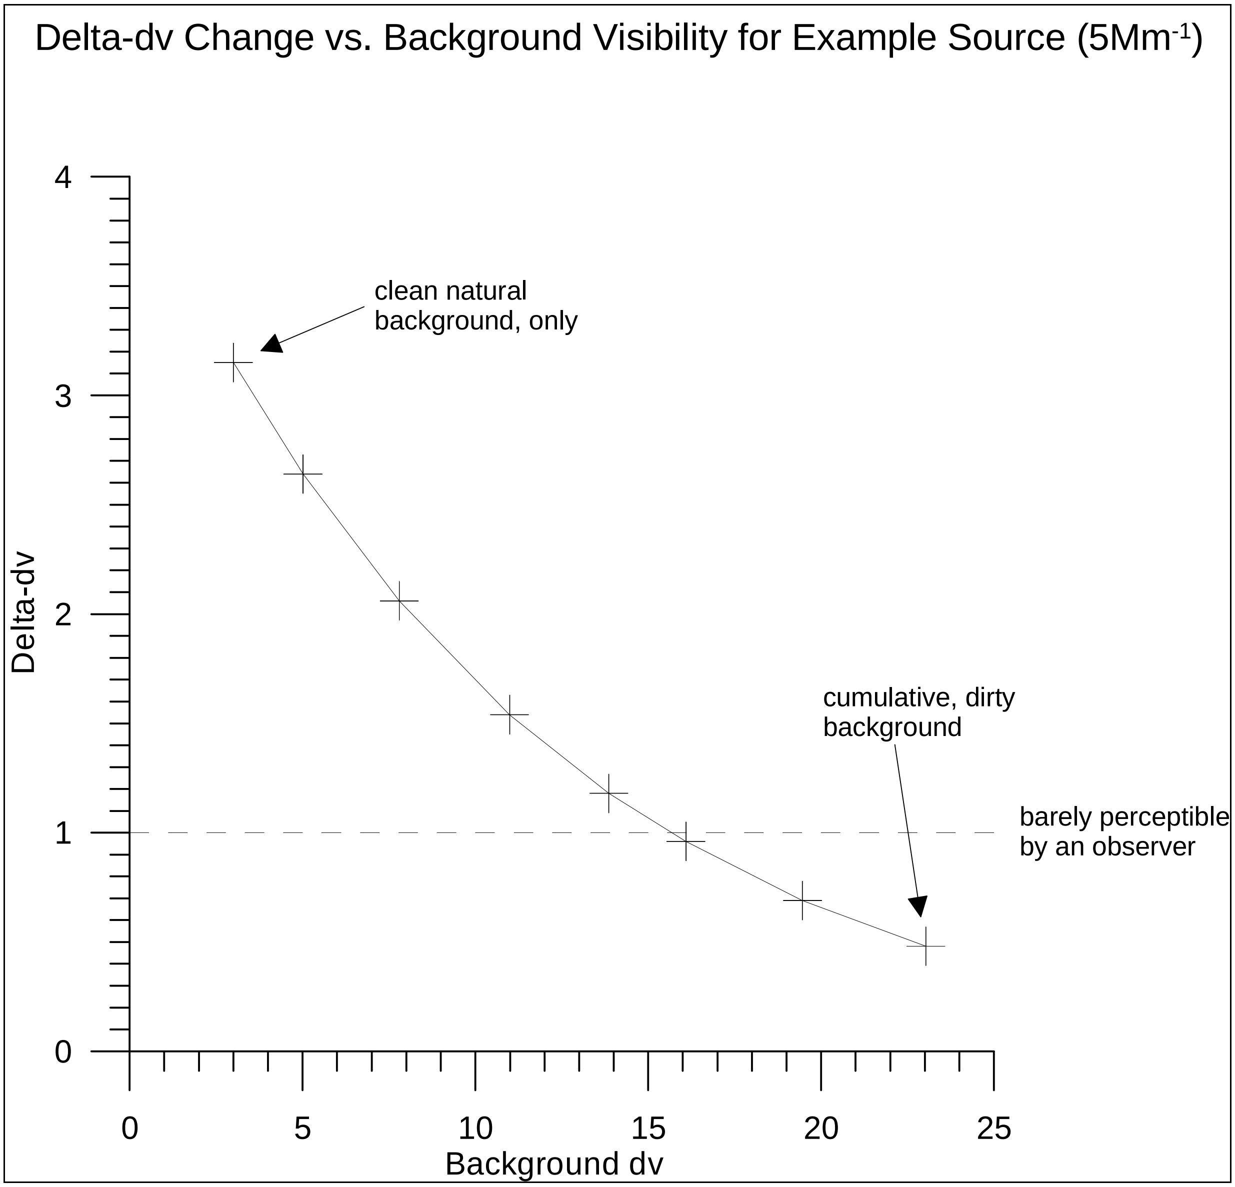
WRAP and the NDDH have found that adding a complete emissions inventory in the cumulative modeling will typically result in a background more than double the natural visibility conditions.

So to complete the example for the cumulative modeling case, we assume a background of 50 Mm^{-1} and the same subject source. Delta-deciview for the subject source would be calculated:

delta-dv = [10 x ln(55 / 10)] – [10 x ln(50 / 10)] = 17.05 – 16.09 = 0.96

Therefore, inclusion of the complete visibility-affecting emissions inventory in the cumulative modeling produces a smaller, but more realistic, observer-detected difference of 0.96 deciview from the subject source. In fact, for this example, the cumulative modeling result falls below the generally recognized observer-detectable threshold of about 1.0 deciview. Thus, the example illustrates that the impact of the subject source plume against a clean background would be much more noticeable to an observer than the impact of the same plume against the more realistic dirtier background. And, obviously, any change in visibility-affecting emissions from the subject source would have a smaller impact on the observer under the cumulative modeling scenario.

In the figure below, delta-deciview has been plotted for several background deciview levels, based on the subject source above. The included background levels range from a clean natural background to a dirty background representing the cumulative effect of many visibility-affecting sources. The plot includes the two points calculated above. The plot illustrates the general dependency of the observed visibility change (delta-deciview) on the background level, and the fact that an observer’s perception of visibility change can vary greatly depending on the background deciview level. In fact, for this example, there is a factor of 6.6 difference in delta-deciview for the cleanest background compared with the dirtiest background (3.15 / 0.48 = 6.56).



To further illustrate the difference in single-source and cumulative visibility analyses, the NDDH conducted additional modeling using actual sources. For this illustration, the NDDH grouped the BART-applicable Coal Creek, Leland Olds, and Milton R Young Generating Stations (in North Dakota) as an effective single source. Single-source and cumulative modeling analyses were conducted to determine the incremental visibility improvement at Theodore Roosevelt National Park from the 3-source group, based on BART controls. Calpuff system versions 5.8, the new IMPROVE equation, annual average natural background, and consistent annual emission rates (for the three noted sources) were applied for both analyses. The 90th percentile visibility day from the single-source modeling results was used to emulate the 20% worst day average from the cumulative modeling results. (Given that the typical distribution of 20% worst day visibilities tends to be skewed toward the high end, the 90th percentile day may somewhat understate the

20% worst day average). Note that the post-BART emissions inventory for the cumulative analysis included changes only to the three sources referenced above.

Results of the NDDH modeling analyses are summarized in the table below. The modeling analyses discussed above are compared in the first two columns of results.

	20% Worst Day Avg. Cumulative Modeling	90th Percentile Day Single-Source Modeling	90th Percentile Day Single-Source Modeling Using 2005 ND BART Protocol
Baseline (dv)	16.954	6.552	5.583
Post-BART (dv)	16.493	5.641	3.288
Improvement (delta-dv)	0.461	0.911	2.295

As shown in the table, visibility improvement from the addition of BART controls to the three generating stations based on single-source modeling is about twice that found from cumulative modeling. These results are consistent with the hypothetical example discussed above.

Also shown in the table are results of a third modeling scenario, i.e., single-source modeling based on the North Dakota BART modeling protocol. Consistent with EPA recommendations at the time (2005), the North Dakota BART protocol specified the use of Calpuff Version 5.7, the old IMPROVE equation, and a natural background reflecting cleanest days. In addition, the protocol specified use of maximum 24-hour emission rates, per the BART Rule. As indicated in the table, use of this protocol resulted in a much greater "apparent" improvement in visibility, about a five-fold increase in the result from the cumulative modeling. This illustration, therefore, is another basis for the NDDH statement in the SIP that BART single-source modeling over predicts by a factor of 5 to 7.

All BART modeling conducted by the NDDH and industry was based on the North Dakota BART protocol. Given differences in the North Dakota BART protocol (compared to later protocols), combined with the logarithmic nature of the relationship between deciview and light extinction, it becomes clear that BART single-source modeling could have greatly overstated the more realistic results obtained from recent cumulative modeling for North Dakota.

Note that use of the ND BART single source modeling produces a visibility improvement at Theodore Roosevelt National Park (2.295 dv) which achieves compliance with the uniform rate of progress goal (2.3 dv as discussed in Section 5 of the North Dakota SIP). If one was to accept the premise that these single-source modeling results are realistic, it would logically follow that North Dakota has met the uniform rate of progress based on BART controls for the three modeled sources, and that the need to address additional (non-BART) visibility-affecting emissions reductions in North Dakota is therefore less compelling.

The 20% worst-day average metric from cumulative modeling and the 90th percentile day metric from single-source modeling have been compared in this illustration as they constitute a comparable moment of the annual distribution of daily visibility predictions. Obviously, the 98th percentile day metric from single-source modeling would provide an even greater exaggeration of actual visibility change than the 90th percentile, in the context of the 20% worst-day average metric required to measure progress with respect to visibility goals under the regional haze rule.

Comment 7: Follow up comment 10C from October 23, 2009

DOI still believes that modeling should be based on the future conditions instead of the year that match the meteorology.

Response: As pointed out previously, the BART Guideline states that the emission rates for determining visibility for the precontrol scenario, the highest emission rates from the meteorological period modeled should be used. When determining visibility improvement, the comparison is made from a baseline, not a future scenario. This affords consistency from state-to-state and allows emissions data to be paired with meteorological data to produce the best prediction of baseline visibility conditions.

Comment 8: Follow up to comment 11 from October 23, 2009

DOI still believes NO_x reductions improve visibility more than SO_2 reductions.

Response: The Department agrees that NO_x reductions may be more effective than SO_2 reductions in reducing some visibility-affecting species' concentrations under some conditions, especially at a generally cooler, northern location versus a warmer, southern location. This is especially true because of the strong temperature dependence of the chemical reaction that forms NO_3 from HNO_3. The following table illustrates the strong temperature and relative humidity dependence of the reaction that forms ammonium nitrate from HNO_3 and the extreme values that can occur given typical values for $[NH_3]$ and $[HNO_3]$ of 1 ppb each. The equilibrium constant of the reaction is K and has an inverse relationship with $[NH_4NO_3]$.

T(deg.C)	T(deg.F)	RH(%)	K(ppb)	$[NH_4NO_3]$(ppb)
40	104	50	1000	0.001
30	86	40	100	0.01
30	86	90	20	0.05
20	68	40	8	0.13
20	68	90	2	0.5

It is recognized that lower temperatures favor production of ammonium nitrate, for example, over production of HNO_3 from NO_x emissions. Conversely, warmer temperatures favor production of HNO_3 over NO_3, including during warmer months in North Dakota. During winter months in North Dakota, lower temperatures produce more potential for higher NO_3 concentrations than in the summer, when potential NO_3 concentrations are relatively low because of warmer temperatures. This temperature effect can be seen in the time-series plots of nitrate concentrations over an annual cycle, displayed in Figure 8.11 of the SIP document. Note the relatively low NO_3 concentrations during the summer and adjacent warmer periods and the higher NO_3 concentrations during the rest of the year.

Nevertheless, potentially higher NO_3 concentrations are only favored in the winter and colder days in spring and fall in North Dakota, and only then when NH_3 and NO_x emissions are high enough, and when winds transport NO_x plumes toward Class I areas and dispersion of plumes is not favorable. During the summer and about half of the spring and fall in North Dakota, ambient temperatures are warmer, similar to the rest of the U.S., and thus high NO_3 concentrations would not be favored then.

It may be true that it is easier to obtain lower NO_3 concentrations from NO_x reductions in a generally cooler, northern location than at a warmer, southern location, because of the temperature dependence in the chemistry. Nevertheless, obtaining visibility improvement by lowering SO_4 concentrations through SO_2 reductions is a reliable, effective way of improving visibility in North Dakota, somewhat because of the less complex chemistry involving SO_2. Reducing SO_2 emissions to improve visibility has the advantage of being effective year round, whereas NO_x reductions would be less effective during warmer months because of the lower potential NO_3 production from the temperature dependence in the chemistry.

Comment 9: Follow up to comment 12 from October 23, 2009

DOI still believes the dollar per deciview improvement is still the metric to emphasize when determining BART.

Response: As far as the emphasis on incremental differences between controls options, see response to comment 6.

DOI apparently did not understand the NDDH response when it pointed out that accuracy of single source modeling when compared to cumulative modeling can vary from state-to-state. As such, the accuracy of a dollar per deciview calculation will vary from state-to-state. This is due to a variation in the number of sources that affect the Class I area, the amount of emissions that affect the area and the location of the sources that affect the area. This makes this metric of very little value.

Comment 10: Follow up to comment 13 from October 23, 2009

DOI believes the proposed SO_2 control technology could meet the lower lb/MMBtu limit (assumed 0.15 lb/10^6 Btu) even if coal quality deteriorates.

<u>Response</u>: The Department did not use the maximum sulfur content in determining the BART limits. The Department used an annual average sulfur content. In the case of Minnkota's M.R. Young Station, the maximum sulfur content is 5.6% with an average of 0.93%. In order to comply with a 0.15 lb/10^6 Btu standard when burning the maximum sulfur coal, the scrubber would have to achieve 98.9% efficiency. This is extremely difficult with a wet scrubber.

<u>Comment 11</u>: Follow up to comment 25 from October 23, 2009

The DOI continues to assert that the WYGEN3 permit should be used as a basis for requiring Stanton Unit 1 to meet a 93% control for SO_2 and an emission limit of 0.09 lb/MM Btu on a 30-day rolling average basis.

<u>Response</u>: The DOI continues to ignore the fact that the WYGEN3 permit does not establish any minimum SO_2 control efficiency, let alone a 93% control efficiency. The WYGEN3 permit only establishes SO_2 emission limits on a lb/hr, lb/MW-hr and lb/MM Btu basis. As stated in the Department's initial response, the WYGEN3 facility could burn low-sulfur coal and still comply with the emission limits with SO_2 control efficiencies below 90%. As also indicated in the Department's initial response, it is the Department's understanding that the WYGEN3 facility has yet to demonstrate that the SO_2 emission limits can be achieved.

The Department maintains the position that a SD/FF operating at Stanton Station Unit 1 is capable of achieving an average SO_2 control efficiency of 90%.

<u>Comment 12</u>: Follow up to comment 26 from October 23, 2009

The DOI states that the "NDDH should show how it arrived at the conclusion that 'based upon the average sulfur content of the coal burned the SO_2 removal efficiency at Stanton Unit 10 is estimated to be approximately 90%.'"

<u>Response</u>: The Department estimated the control efficiency based upon data contained in the annual emission inventory report for the Stanton Unit 10 facility. Uncontrolled emissions were calculated based upon AP-42 emission factors. Actual (controlled) emissions are measured by the CEM at Stanton Unit 10. This data is public information which will be provided to the DOI upon request.

<u>Comment 13</u>: Follow up to comment 29 from October 23, 2009

The DOI asserts that it may be possible that SOFA with SCR with reheat may be less expensive than just SCR with reheat since the additional capital cost of adding SOFA may be offset by reduced annual operating costs.

<u>Response</u>: The DOI provides no data to support this position. The BART analysis for the M.R. Young facility estimates the annualized cost for SCR with reheat with ASOFA to be approximately \$99,600 to \$143,570 per MWe. The estimated annualized cost for SCR with reheat at Stanton Unit 1 is approximately \$66,435 per MWe. Based upon this data, the cost of adding ASOFA is expected to significantly increase the annualized cost. Although adding SOFA may be somewhat less expensive than adding ASOFA, in the Department's judgment it is very likely that the cost of SOFA with SCR with reheat will be higher than the cost of SCR with reheat alone.

In the specific case of the BART analysis for Stanton Unit 1 the incremental cost of applying SCR with reheat is $10,032 per ton of NO_x controlled when burning lignite and $12,894 per ton of NO_x controlled when burning PRB. It would be necessary for the addition of SOFA to reduce the incremental costs considerably for the application of SOFA with SCR with reheat to not be considered cost prohibitive. As indicated above, it is very likely that the addition of SOFA would increase costs significantly and not decrease costs significantly. Therefore, in the Department's judgment an analysis of SOFA with SCR with reheat would not alter the conclusion that SOFA with SCR with reheat is cost prohibitive at Stanton Unit 1.

Comment 14: Follow up to comment 30 from October 23, 2009

The DOI continues to question the cost estimates for SCR with reheat included in the BART analysis.

Response: In previous comments submitted by DOI, the DOI questioned GRE's estimate of the capital cost of SCR with reheat of $301/kW based upon the fact that the cost exceeded what the DOI deemed to be an acceptable range of $50-$267/kW. The DOI bases the acceptable range on a cost survey and one of the documents referenced by DOI includes a June 26, 2008 technical memorandum prepared by Eastern Research Group, Inc. (ERG) regarding the PGE Boardman Plant. In this document, ERG references an acceptable cost range for SCR (apparently without reheat or gas-to-gas heat exchanges – GGHE) of $207-$267/kW. However, the ERG memorandum also references a cost estimate prepared by Black & Veatch and CH2M Hill for the PGE Boardman Plant of $309/kW (apparently for SCR without reheat). The Black and Veatch / CH2M Hill cost estimate was not referenced by the DOI. Based on the GRE BART submittal, the capital cost estimate for addition of the thermal oxidizer necessary to reheat the flue gas is approximately $1.275 million (approximately $7 per kW). Adding this to the above-referenced ERG cost ranges results in a range of approximately $214-$274/kW. Adding the $7 per kW cost to the Black and Veatch / CH2M Hill cost estimate results in a cost estimate of approximately $316/kW.

Based on the above, it can be seen that the GRE capital cost estimate for SCR with reheat of $310/kW is approximately 10% higher than the highest cost value of $274/kW prepared by ERG (adjusted for SCR with reheat but without the GGHE). The GRE capitol cost estimate for SCR with reheat is approximately 2% lower than the cost estimate of $316/kW prepared by Black and Veatch / CH2M Hill for the PGE Boardman Plant (adjusted for SCR with reheat but without the GGHE). Based upon this data, the GRE cost estimates appear to be in the range of similar cost estimates. This is especially true considering the inherent difficulty in calculating actual costs. Both the New Source Review Workshop Manual and the EPA Air Pollution Control Cost Manual state that control cost estimates are typically accurate within ± 20 to 30 percent. Based upon the above, the GRE cost estimate for SCR with reheat appears to be reasonable.

The DOI also continues to question how the Department verified the cost estimates. An example of how the Department verifies cost estimates is shown above. As can be seen from the above, the Department verified the cost estimates by comparing the calculated costs with all relevant data. The Department also verifies the actual calculations to determine if the values used are reasonable. Based on the ongoing comments, it appears that the DOI has relied on outdated models to estimate costs. As the Department has demonstrated in previous responses to DOI comments, the DOI cost estimates for other projects have been found to be significantly lower than EPA cost estimates for the same projects.

Comment 15: Follow up to comment 34 from October 23, 2009

DOI is suggesting a higher efficiency for SCR.

Response: See response to comment 4.

Comment 16: Follow up to comment 35 from October 23, 2009

DOI claims that the NDDH cannot simply halt the BART process by determining that a technically feasible option is too expensive on a cost per ton basis.

Response: The preamble to the BART guideline states "The interpretation of the requirements of the regional haze program reflected in the discussion above does not necessitate costly and time-consuming analyses. Consistent with the CAA and the implementing regulations, States can adopt a more streamlined approach [emphasis added] to making BART determinations where appropriate. Although BART determinations are based on the totality of circumstances in a given situation, such as the distance of the source from a Class I area, the type and amount of pollutant at issue, and the availability and cost of controls, it is clear that in some situations, one or more factors will clearly suggest an outcome. Thus, for example, a State need not undertake an exhaustive analysis of a source's impact on visibility resulting from relatively minor emissions of a pollutant where it is clear that controls would be costly and any improvements in visibility resulting from reductions in emissions of that pollutant would be negligible." (F.R. Vol. 70, No. 128, p.39116). The cost of SCR is obviously excessive. Based on the visibility modeling results from Unit 2, the amount of improvement is visibility in any Class I area will be less than 0.01 deciviews in the most impaired days or approximately 0.10 deciviews (overall average) based on the 98th percentile value from the single source modeling when compared to the next best control technology. This amount of visibility improvement is negligible.

The Department is free to weigh the five factors as we choose (FR Vo. 70, No. 120, p.39130). As we have indicated, visibility improvement has been given little weight in the BART process. In the case of a control technology that is obviously excessive in cost on a dollar per ton basis, visibility improvement was given even less weight. That is, a control option that has an excessive cost on a dollar per ton basis, there is no reason to model the visibility improvement because visibility improvement will be a small part of the decision making process. There are literally dozens of control options with varying degrees of removal efficiency that could be analyzed. To make a workable BART process, not all options can be modeled to determine the amount of visibility improvement.

Comment 17: Follow up to comment 37 from October 23, 2009

DOI believes visibility modeling must be done for SOFA + SCR and SCR.

Response: See response to comment 16.

Comment 18: Follow up to comment 49 from October 23, 2009

DOI is advocating a startup limit (lb/hr) based on the BART allowable and the maximum rated heat input of the unit.

Response: For wall and tangentially fired boilers, the DOI suggestion may work. Because cyclone boilers emit at such a high rate during startup (>1.0 lb/10^6 Btu), limiting the emissions based on DOI suggestion does not provide the relief necessary. The unit would exceed the lb/hr limitation when the heat input is only 1/3 of the rated capacity or less. This would lead to extended periods of noncompliance. The NDDH believes the proposed limit is necessary for Minnkota since they did not include startups in the proposed BART limit. The Consent Decree for Minnkota requires these limits to be established separately.

Comment 19: Follow up to comment 54 from October 23, 2009

Same comment as comment 23 except for M.R. Young Unit 2.

Response: See response to comment 18.

Comment 20: Follow up to comment 63 from October 23, 2009

DOI indicated that NDDH should seriously evaluate all significant sources of human-caused impairment. They also questioned whether cumulative visibility improvement cited in the SIP included controls on Coyote and AVS.

Response: The NDDH considered all the significant sources of visibility impairing pollutants including any source that emits more than 100 tons per of sulfur dioxide and nitrogen oxides combined, oil and gas production facilities, prescribed burning, agricultural tillage operations and mobile sources. The NDDH believes this represents nearly all of the SO_2 and NO_x emissions from anthropogenic sources. The analysis that was conducted indicates it is not reasonable to control these sources.

The cumulative visibility modeling shown in the SIP did include controls for Coyote and AVS. For Coyote Station, this included a new wet scrubber plus ASOFA + SNCR. For AVS, this included LNB + SNCR.

Subject: Regional Haze Plan

Director Terry O'Clair
North Dakota Dept. of Health, Div. of Air Quality
918 E Divide Avenue, Second Floor
Bismarck, ND 58501-1947

Dear Director O'Clair,

My grandfather homesteaded in the badlands, and my dad grew up there. My sister and I spent most weekends there, and I have a deep appreciation for the beauty, and also the pollution free air there. Thank you for the opportunity to comment on North Dakota's proposed regional haze plan. As a national park visitor and advocate for the parks, I value the beauty of Badlands, Theodore Roosevelt, and Wind Cave National Parks. I understand that the state's haze plan offers an unprecedented opportunity to clean up the air in these parks, which are affected by pollution from power plants and other industry. Air pollution from North Dakota's coal plants and industry also impacts national parks in Minnesota and Michigan, as well as four large wilderness areas.

The Clean Air Act requires old power plants and factories to reduce haze-causing pollutants. Technology exists to reduce this pollution--technology that will protect our national parks and wilderness areas, and public health. It is important that the Act and other air quality regulations are followed, so that we can enjoy these parks now and preserve them for our children and grandchildren.

The State of North Dakota can and should do more to protect our air quality as it implements the Regional Haze Rule. I request that the haze plan impose stricter limits on pollution from power plants and other industrial sources. In particular, North Dakota should require all appropriate coal plants to install more effective pollution control devices, and more aggressively pursue identified emission reductions from all sources.

Without this and other measures, North Dakota's coal plants will continue to unnecessarily obscure views in our national parks and wilderness areas for decades to come and deter tourists, including me and my family, from visiting the state of North Dakota and the beloved parks in the region. North Dakota must do its part to ensure that the air in our parks, and throughout the region, will indeed be restored to natural conditions.

Thank you for considering my comments.

Sincerely,
Alice Christianson

In particular, North Dakota should require all appropriate coal plants to install more effective pollution control devices, and more aggressively pursue identified emission reductions from all sources.

Without this and other measures, North Dakota's coal plants will continue to unnecessarily obscure views in our national parks and wilderness areas for decades to come and deter tourists, including me and my family, from visiting the state of North Dakota and the beloved parks in the region. North Dakota must do its part to ensure that the air in our parks, and throughout the region, will indeed be restored to natural conditions.

Thank you for considering my comments.

Sincerely,
Aaron Gayken

Subject: Regional Haze Plan

Director Terry O'Clair
North Dakota Dept. of Health, Div. of Air Quality
918 E Divide Avenue, Second Floor
Bismarck, ND 58501-1947

Dear Director O'Clair,

Thank you for the opportunity to comment on North Dakota's proposed regional haze plan. As a citizen of North Dakota, a national park visitor and advocate for the parks, I value the beauty of Badlands, Theodore Roosevelt, and Wind Cave National Parks. I understand that the state's haze plan offers an unprecedented opportunity to clean up the air in these parks, which are affected by pollution from power plants and other industry. Air pollution from North Dakota's coal plants and industry also impacts national parks in Minnesota and Michigan, as well as four large wilderness areas.

The Clean Air Act requires old power plants and factories to reduce haze-causing pollutants. Technology exists to reduce this pollution--technology that will protect our national parks and wilderness areas, and public health. It is important that the Act and other air quality regulations are followed, so that we can enjoy these parks now and preserve them for our children and grandchildren.

The State of North Dakota can and should do more to protect our air quality as it implements the Regional Haze Rule. I request that the haze plan impose stricter limits on pollution from power plants and other industrial sources. In particular, North Dakota should require all appropriate coal plants to install more effective pollution control devices, and more aggressively pursue identified emission reductions from all sources.

Without this and other measures, North Dakota's coal plants will continue to unnecessarily obscure views in our national parks and wilderness areas for decades to come and deter tourists, including me and my family, from visiting the state of North Dakota and the beloved parks in the region. North Dakota must do its part to ensure that the air in our parks, and throughout the region, will indeed be restored to natural conditions.

Thank you for considering my comments.

Bismarck, ND 58501-1947

Dear Director O'Clair,

Thank you for the opportunity to comment on North Dakota's proposed regional haze plan. As a national park visitor and advocate for the parks, I value the beauty of Badlands, Theodore Roosevelt, and Wind Cave National Parks. I understand that the state's haze plan offers an unprecedented opportunity to clean up the air in these parks, which are affected by pollution from power plants and other industry. Air pollution from North Dakota's coal plants and industry also impacts national parks in Minnesota and Michigan, as well as four large wilderness areas.

The Clean Air Act requires old power plants and factories to reduce haze-causing pollutants. Technology exists to reduce this pollution--technology that will protect our national parks and wilderness areas, and public health. It is important that the Act and other air quality regulations are followed, so that we can enjoy these parks now and preserve them for our children and grandchildren.

The State of North Dakota can and should do more to protect our air quality as it implements the Regional Haze Rule. I request that the haze plan impose stricter limits on pollution from power plants and other industrial sources. In particular, North Dakota should require all appropriate coal plants to install more effective pollution control devices, and more aggressively pursue identified emission reductions from all sources.

Without this and other measures, North Dakota's coal plants will continue to unnecessarily obscure views in our national parks and wilderness areas for decades to come and deter tourists, including me and my family, from visiting the state of North Dakota and the beloved parks in the region. North Dakota must do its part to ensure that the air in our parks, and throughout the region, will indeed be restored to natural conditions.

Thank you for considering my comments.

Sincerely,
marcella gilbert

8 January 2009

Dear Terry O'Clair:

I'm writing to submit a comment regarding the recent draft of the North Dakota State Implementation Plan (SIP) to reduce haze. Given the fact that the Theodore Roosevelt National Park is protected from man-made haze in the Clean Air Act and that man-made pollution from North Dakota power plants and industry is contributing to the haze in our national parks, it is very important that the ND SIP be revised to strengthen the regulations on our local coal-fired power plants. Burning approximately 30 million tons of coal each year, they are a major source of haze for our state and a substantial risk to our citizens' health.

The Clean Air Act requires ND to create a plan to reduce air pollution contributing to that haze, however ND's draft plan released last week fails to require strict enough limits for our state's largest pollution sources: the eight aging power plants, many of which were grandfathered in, therefore they have been allowed to pollute much more than the Clean Air Act's standards target. It is crucial for our state to use this moment to make the long-needed change and be more aggressive about protecting our people and natural resources, especially the quality of our air, land and water. Reducing air pollution from burning coal is the crucial step in protecting all three of these areas, since what goes up into the air inevitably ends up in our soil and water, thus in our citizens' bodies.

I ask that you revise and increase the controls in the SIP not only to protect our land and citizens, but also to protect and stimulate our sustainable economy. In every way, moving away from fossil fuels will benefit our state economically. It will force coal plants to move into sustainable- and in the long run- more inexpensive and profitable sources of energy. The price of burning fossil fuels will continue to rise as we start to pay for the externalities and as the international and national laws become stronger, which they are and are projected to continue to do. The income from green and sustainable energies, which ND has an abundant supply of, is continually rising and projected to rise. ND has already seen millions and even hundreds of millions of dollars invested in its wind farms, which needs to be further encouraged. A PEW study in 2009 stated that jobs in renewable energy outnumber jobs in the regular sector in ND by a margin of 3-to-1. So, raising the limits on coal may appear to be an economic loss in the short term, but it will certainly stimulate greater economic benefits, and a more stable future economy for our state in the long term.

Tourism is another aspect of our ND economy that we have to remember when considering revisions to the SIP. Tourism is such a large part of our ND economy, so we really need to protect our natural ecosystems from pollution in order to preserve these areas, as well as protect the people's health who visit them and keep the visibility as clear as possible so people can experience the majesty of these beautiful views. Every year I camp and hike in the Theodore Roosevelt National Park. The park is very important to me and many people I know. The friends I've taken there from out-of-state are always impressed by the visibility and "how far they can see", so it is really something we need to take seriously and protect from haze. In closing, I'd like to reiterate that this is both a health issue as well as an economic issue for our state, and the coal plants' pollution threatens them both.

For these and many other common sense reasons, I urge the ND State Health Department to revise and strengthen the air pollution controls in the ND SIP.

Thank you for hearing my request.

Sincerely,

James Kambeitz

Re: Comments on the North Dakota Department of Health Proposed Amendment to the State Implementation Plan (SIP) for Reducing Regional Haze

Dear Mr. ~~O'Clair~~ Terry:

Montana Dakota Utilities Co. (Montana-Dakota) submits the following comments on the North Dakota Department Health's (NDDH) proposed amendment to the State Implementation Plan (SIP) for reducing Regional Haze.

Montana-Dakota generates, transmits and distributes electricity and distributes natural gas in North Dakota, South Dakota, Montana and Wyoming. The company owns and operates electric steam generating facilities which are subject to extensive regulation under the Federal Clean Air Act. The following comments concern issues pertaining to R.M. Heskett Station Unit 2 (Heskett Unit 2) in the draft Regional Haze SIP.

Level of Emission Reduction from Voluntary Commitment

The NDDH included language in the last paragraph of Section 7.3.4 of the SIP, page 68, discussing a voluntary commitment by Montana-Dakota to reduce potential sulfur dioxide emissions in the future from Heskett Unit 2 by a minimum of 70 percent. The NDDH states in the SIP document that this commitment will reduce sulfur dioxide emissions to 1,660 tons per year at Heskett Unit 2 from its 2000-2004 emissions of 2,400 tons per year, yielding a 740 tons per year reduction. Montana-Dakota has calculated a projected average annual reduction of sulfur dioxide emissions of 474 tons per year that better represents the 70 percent reduction of sulfur from coal to stack during a normal operating year when adding limestone. This value, instead of 740 tons per year, should be used and is further explained in the following paragraphs.

The 2,400 tons per year NDDH cited in the SIP is an average sulfur dioxide emissions rate over the 2000-2004 time period. During this period, emissions varied from a minimum of 1,778 tons per year in year 2000 to a maximum of 2,754 tons per year in year 2004. The lower annual emissions are mainly due to plant shut downs, while the higher annual emissions are due to increased demand growth over time.

Montana-Dakota calculates the expected sulfur dioxide emission reduction by comparing emissions projected for a normal operating year when adding limestone to Heskett Unit 2 to the average sulfur dioxide emissions resulting from the higher operating years in 2000-2004. The higher emissions years are 2001 at 2,625 tons, 2003 at 2,650 tons, and 2004 at 2,754 tons, yielding an average of 2,676 tons of sulfur dioxide for a baseline annual average emissions rate.

To calculate the projected annual average sulfur dioxide emission rate for a normal operating year when adding limestone, Montana-Dakota made the following determinations and calculations. First, the average sulfur in coal from the 2000-2004 time period was approximately 0.72 percent, with an average heat content of the coal at 7,176 btu/lb. We then used Equation 19-25 from EPA Method 19 to calculate an average uncontrolled sulfur dioxide emission rate of approximately 2.01 lb/mmbtu. With limestone addition, Heskett Unit 2 could achieve a sulfur dioxide emission rate of approximately 0.60 lb/mmbtu, which assumes a 70 percent level of control from the uncontrolled emission rate of 2.01 lb/mmbtu. During a normal operating year with limestone addition, and assuming an approximate 91% availability (representing the average availability in 2001, 2003 and 2004), Heskett Unit 2 would be expected to emit approximately 2,202 tons of sulfur dioxide per year (2.01 lb/mmbtu x 916.5 mmbtu/hr x 7,971 hr/year (annual 91% availability) / 2000 lb/ton x 30% = 2,202 ton/year).

Based on the above, Heskett Unit 2 would expect to achieve an average annual sulfur dioxide emissions reduction of approximately 474 tons per year, which reflects the baseline emissions of 2,676 tons per year less the projected 2,202 tons per year with limestone control. If the NDDH should choose to include in the Regional Haze SIP a projected sulfur dioxide emission reduction associated with Montana-Dakota's voluntary commitment, Montana-Dakota could only support a projected average annual reduction of 474 tons per year.

Supporting SIP Documentation for Heskett Unit 2

We assume that the Appendices A.2 and A.3 to the final Regional Haze SIP will be updated and revised to include copies of: (1) the document titled, "CALPUFF Visibility Modeling Protocol: MDU Heskett Unit 2 BART Analysis" prepared by AECOM and dated November 25, 2009; (2) the NDDH and EPA Region 8 approvals of the November 25, 2009 BART modeling protocol for Heskett Unit 2, which include an e-mail from S. Weber, NDDH, to B. Paine, AECOM dated December 1, 2009, an e-mail from S. Weber, NDDH to K. Golden, EPA Region 8, dated December 1, 2009, and an e-mail from K. Golden, EPA Region 8, to S. Weber, NDDH, dated December 10, 2009); (3) a copy of the document titled "Updated BART CALPUFF Visibility Modeling Analysis for Montana-Dakota Utilities Heskett Station Unit 2," dated December 17, 2009, which sets forth the most recent visibility modeling analysis for Heskett Unit 2 (this document is currently included in the draft Regional Haze SIP documents, however, it is located at the bottom of the NDDH's webpage http://www.ndhealth.gov/AQ/RegionalHaze/); and (4) the December 21, 2009 NDDH correspondence to EPA Region 8 which states that Heskett Unit 2 is exempt from BART.

Reasonable Further Progress Goals

The federal Regional Haze Rules require NDDH to set reasonable progress goals (RPGs) toward meeting a national goal of natural visibility conditions in Class I areas by the year 2064. The federal rules identify four factors that must be considered in evaluating potential added emission control measures to meet RPGs, including: (1) the cost of compliance; (2) the time necessary for compliance; (3) energy and non-air quality environmental impacts of compliance; and (4) the remaining useful life of any existing source subject to such requirements. See e.g., "Supplementary Information for Four-Factor Analyses for Selected Individual Facilities in North Dakota," dated May 18, 2009, Revised Draft Report Prepared by: B. Nelson, W. Battye, and J. Hou, EC/R Incorporated.

As part of applying the RPG analysis to Heskett Unit 2, Montana-Dakota expects the NDDH to consider the degree of visibility improvement on a deciview (dv) basis and a cost per deciview improvement basis ($/dv) that would result from additional controls, since this is the approach the NDDH followed when evaluating emissions from other RPG sources in the State. At the public hearing held today on the proposed Regional Haze SIP, we understood NDDH to confirm that Heskett Unit 2 has been subject to RPG analysis. The analysis considered the degree of deciview improvement that would result from a 95 percent level of sulfur dioxide emission control. The analysis showed inconsequential deciview improvements at Theodore Roosevelt National Park (0.009 dv) and at Lostwood National Wildlife Refuge (0.003 dv). Based on the outcome of the analysis, NDDH stated that it would not require additional controls for Heskett Unit 2 under the RPG element of the SIP. While Montana-Dakota endorses this outcome, analyzing the incremental costs of control per deciview improvement would further support the NDDH's RPG conclusions with respect to Heskett Unit 2.

If you have any questions or would like to discuss our comments, please contact me at 222-7844.

Sincerely,

Abbie Krebsbach

Dear Terry ~~Mr. O'Clair~~:

We appreciate the effort you and your staff have devoted to responding to the comments we provided during consultation on your State Implementation Plan (SIP) revision to address regional haze requirements of 40 CFR 51.300-308. However, after reviewing your "Response to DOI Comments" document, we believe that there are still some outstanding issues that warrant further consideration as you prepare the SIP revision for submittal to EPA Region 8. Specifically, we still contend that Theodore Roosevelt National Park (NP) should be treated in all impact assessments as one Class I area (not three separate areas), and that additional controls (e.g., Selective Catalytic Reduction) is Best Available Retrofit Technology (BART) for some BART-eligible units. Our follow-up comments are discussed in more detail below and in the enclosed document.

Treatment of Theodore Roosevelt NP

We appreciate your acknowledgement that Theodore Roosevelt NP is only one Class I area under the Clean Air Act. However, we disagree that units of the park can be separated when assessing visibility impairment for the purposes of determining if an existing source causes or contributes to visibility impairment under the Regional Haze Rule. Your response cites the definition of "adverse impact on visibility" which is a definition that applies for assessment under Section 51.307 regarding impacts of new sources. For purposes of applying Best Available Retrofit Technology (BART) to existing sources, or determining if an existing source could be controlled to aid in "reasonable progress" toward the national visibility goal of no human-caused impairment, a State should consider if a source contributes to "visibility impairment." Section 51.301 (x) defines visibility impairment as "any humanly perceptible change in visibility (light extinction, visual range, contrast, coloration) from that which would have existed under natural conditions." U.S. Environmental Protection Agency rules for applying BART establish a test for "contribution" of sources as 0.5 deciview impact for the 98th percentile day over a three-year period. That impact applies to all locations (i.e., receptors) within a Class I area for the modeled three-year period. In the case of Theodore Roosevelt NP, modeling receptors are only located within the boundaries of the three individual units of the Class I area. Since lands outside of the Class I area are not included in assessing the 0.5 deciview impact, there is no misrepresentation of impacts for park visitors, and there is no extension of Class I status to areas outside of the park.

If receptors within the total park boundary show 0.5 or more deciview impacts (98th percentile day) over the three-year period, a BART-eligible source's emissions contribute to "visibility impairment" and must be assessed under EPA's regional haze BART guidance. We believe that this test is useful for any stationary source to identify those sources or groups of sources that should be evaluated for reasonable progress as well.

Best Available Retrofit Technology (BART) Analyses

We have reviewed the responses you provided to our comments on assessing BART controls. The enclosed follow-up comments supplement the concerns we have raised in light of your responses.

We have received a letter dated December 21, 2009, regarding new results of air quality modeling to determine if the Heskett Power Plant is subject to BART. We are coordinating with U.S. EPA Region 8 staff in their efforts to verify the new modeling results. Pending the outcome of the review, we may provide additional comments on these new modeling results.

Finally, we have recently become aware that Regenerative Selective Catalytic Reduction (SCR) is an available technology that is applicable to Electric Generating Units and has the potential to allow SCR to be installed on a relatively cool gas stream (e.g., following a scrubber) with relatively little auxiliary heat required. The primary drawbacks to this Regenerative SCR are the capital cost and space requirement, but this technology warrants further evaluation as possible BART for North Dakota sources.

Again, we appreciate your State's efforts to build a foundational SIP for the purposes of addressing regional haze and visibility protection in general for our national treasures. We look forward to working with the State to continue progress toward the national visibility goal.

Sincerely,

John Bunyak

Department of the Interior (DOI) Follow-up Comments on North Dakota Department of Health (NDDH) Best Available Retrofit Technology (BART) Analyses
January 8, 2010

DOI Comment 6: (Purpose of the BART Program)
The core purpose of the BART program is to improve visibility in our Class I areas. BART is not necessarily the most cost-effective solution. Instead, BART represents a broad consideration of technical, economic, energy, and environmental (including visibility improvement) factors. We believe that it is essential to consider both the degree of visibility improvement in a given Class I area as well as the cumulative effects of improving visibility across all of the Class I areas affected.

NDDH Response: In determining BART, visibility improvement was generally not weighted as heavily as the cost of compliance because we believe the single source modeling required by the BART guideline does not give a true representation of the degree of improvement in visibility **which may reasonably be anticipated to result from the use of the technology.**

We believe the cumulative visibility effects analysis promoted by DOI is scientifically unsound and not in accordance with rule or law. Adding the maximum improvement value (or 98th percentile) at one Class I area to the maximum improvement at another Class I area does not account for these maximums happening at different times. In addition, DOI has not defined which Class I areas should be added together to achieve the cumulative impact. This makes the analysis arbitrary. The single source modeling under BART does not provide a realistic estimate of visibility improvement of a given technology. Creating a "cumulative effects" analysis based on the flawed BART analysis only compounds the inaccuracy and misleads the reader of the SIP.

In addition, the BART Guideline only requires an evaluation of the change at each receptor. It does not require adding these changes together.

DOI Follow-up: In light of the NDDH's perceived problems with the suggested DOI approach, the NDDH should explain how it considered the benefits of reducing emissions with respect to visibility improvements at multiple Class I areas.

DOI Comment 8: The ability of SCR to reduce emissions, as assumed by NDDAQ, was inconsistent and sometimes underestimated.

NDDH Response: In the ANPR for the Four Corners Power Plant (Federal Register 8/28/09) EPA states "APS estimated that SCR could achieve NO_x control of approximately 90% or greater from the baseline emissions. For new facilities, 90% or greater reduction in NO_x from the SCR can be reasonably expected. See May 2009 White Paper on SCR from Institute of Clean Air

Companies. For SCR retrofits on an existing coal-fired power plant, Arizona Department of Environmental Quality (ADEQ) determined that 75% control from SCR (following upstream reductions by LNB) was appropriate for the Coronado Generating Station in Arizona. Based on this data, EPA has determined that an 80% control efficiency for SCR alone, rather than the 90+% control assumed by APS, is appropriate". The Department believes 80% is a reasonable estimate that allows the source to comply with the expected emission limit on a continuous basis.

DOI Follow-up: We have advised EPA Region 9 that it has underestimated the ability of SCR to reduce NO_x emissions from the sources in question and supported our comments with real-world data from actual retrofits to coal-fired EGUs. Our comments can be found in the same docket accessed by NDDH.

DOI Comment 9: The cost of SCR was consistently overestimated.

NDDH Response: The DOI used the EPA Air Pollution Control Cost Manual (February 1996) to estimate the capital cost and operating costs for the SCR system. The DOI did not use the most current version of this manual which is dated January 2002.

DOI Follow-up: We used the current version of the Cost Manual as it pertains to SCR.

NDDH Response: The EPA Air Pollution Control Cost Manual (both versions) is significantly out-of-date for estimating costs for SCR. This can be seen from the recently published results of EPA's review of the Four Corners Power Plant BART analysis. In the Advanced Notice of Proposed Rulemaking (August 28, 2009), EPA published the Consultant's, EPA's and the National Park Service's estimate of the cost for NO_x controls.

DOI Follow-up: We have advised EPA Region 9 that it has overestimated the cost of SCR to reduce NO_x emissions from the sources in question. Our comments can be found in the same docket accessed by NDDH.

NDDH Response: It would appear the NPS is underestimating annualized SCR costs by as much as a factor of 6 and cost effectiveness by as much as a factor of 3. The discrepancy between the annualized cost and the cost effectiveness is apparently due to the NPS overestimating the effectiveness of SCR. Based on this apparent underestimation, it appears the costs provided by the consultants and the Department's estimates are similar to EPA estimates and are reasonable. Any estimate by the FLM of cost on a dollar per deciview basis would be similarly flawed.

DOI Follow-up: NDDH should conduct an independent analysis by applying the EPA-recommended OAQPS Control Cost manual.

NDDH Response: As pointed out earlier, the OAQPS Control Cost Manual is out-of-date. EPA accepted estimates based on the CUE Cost Model for the Four Corners Power Plant BART analysis. Since the OAQPS Control Cost Manual is out-of-date and drastically underestimates control costs, we believe the CUE Cost Model provides a more realistic estimate of the costs.

DOI Follow-up: EPA Region 8 recommended that NDDH use the OAQPS Control Cost manual, and we support the EPA position on this matter.

DOI Comment 10: (Step 5: Visibility Improvement)
A) DOI believes it is appropriate to consider both the degree of visibility improvement as well as cumulative effects.
B) DOI is concerned that the Department did not provide the total improvement for each BART option.

NDDH Response: The total improvement under BART is not the best metric for addressing visibility associated with each option since the single source modeling under BART over predicts (by a factor of 5-7) the actual improvement in North Dakota. Incremental differences in improvement provides an easy way to evaluate the visibility improvement benefits of one option over another. The difference is equivalent to the total improvement of one option minus the total improvement of the other option. Providing the total improvement will mislead the reader of the SIP because of the over prediction. However, this information can be extracted from the analyses conducted by the operators of the BART sources. .

DOI Follow-up: NDDH is placing too much emphasis upon incremental differences; NDDH should provide the total improvement. In addition, we do not understand how NDDH can claim that the BART modeling over predicts (by a factor of 5-7) because in the Leland Olds Station Unit 1 and 2, and the Milton R. Young Unit 1 and 2 BART protocols, NDDH itself states: "The NDDH modeling protocol recommends a specific version of the CALPUFF modeling system as modified by the NDDH to specifically address terrain, climate, and emission characteristics of LOS / MRYS. ... The input files contained the specific coordinate grid points, wind field options, terrain, dispersion options, receptor coordinates and plume characteristics and other model parameters that the NDDH has determined best represents the region. The NDDH version of CALPUFF was used for modeling." Therefore, NDDH should support its claims that "the single source modeling under BART over predicts (by a factor of 5-7) the actual improvement in North Dakota."

DOI Comment 10: C) DOI is concerned about the difference in their modeling for Leland Olds Unit 2 and the Department's and Basin Electric's modeling results (the latter two sets of results agree closely).

NDDH Response: There are bound to be differences in modeling results when different model settings and options are used as well as different receptor grids. One error noted in the DOI modeling results was the input for the maximum 24-hour SO_2 emission rate for Unit 2. DOI used 17,610 lb/hr plus 1,581 lb/hr for sulfate. Unit 2 had a maximum 24-hour SO_2 (includes SO_4) of 12,205 lb/hr during the baseline period (2000-2004). DOI apparently used an SO_2 + SO_4 emission rate based on maximum future sulfur content. This is incorrect since current visibility conditions (12,205 lb/hr) are compared to conditions after controls are applied. The BART Guideline states "Use the 24-hour average actual emission rate from the highest emitting day of the meteorological period modeled (for the pre-control scenario)". The meteorological data used by the Department is from 2000-2004. Use of potential future uncontrolled emissions for the precontrol scenario is inconsistent with the BART guideline. The Department also noted that this error carried over into the emission rates for other pollutants. This error will provide a much greater improvement in visibility as found by the DOI.

DOI Follow-up: We agree with NDDH's method of assessing future emissions and control costs and effectiveness based upon anticipated changes in coal quality. We, therefore, believe that it is appropriate to model changes in visibility impairment on the same bases. The SO_2 emission rate was provided by Basin Electric in "Table 1.3-2 – Leland Olds Station Future PTE Emissions for BART Analysis". The sulfate emissions were derived from our PM speciation workbook and account for all condensible inorganic emissions. We invite NDDH to discuss this matter further.

DOI Comment 11: It appears to be more beneficial to reduce NO_x than to reduce SO_2 in this cool climate.

NDDH Response: The Department does not necessarily agree with this statement. There are situations in North Dakota where reduction in NO_x has very little impact on visibility. This can be seen from the AVS I analysis. A 65% reduction NO_x (2,356 tpy) only provided a 0.01 deciview improvement in the average of the 20% worst days.

DOI Follow-up: AVS 1 was not subject to BART, and thus not reviewed in that context. If one considers the relative visibility benefits of reducing SO_2 versus NO_x (on a per-ton basis) <u>at a given EGU that was subject to BART</u>, it appears to be more beneficial to reduce NO_x than to reduce SO_2 in this cool climate.

DOI Comment 12: DOI recommends more emphasis on the dollar per deciview metric.

NDDH Response: There was no established data base for this metric when the BART analyses were developed and when the Department was making its decisions. Even the DOI's data is not very useful since the EPA has not approved the BART determinations in that database. Again, the single source modeling does not reflect the true visibility improvement. It may be more realistic in some states than in others. Therefore, the comparison of $/deciview in North Dakota to $/deciview in another State is not an apples-to-apples comparison. The Department has considered the incremental visibility improvement between BART options. We believe this is the best metric given the limitations of single source modeling to provide realistic estimates of visibility improvement.

DOI Follow-up: NDDH has placed too much emphasis upon incremental differences and should explain what benchmarks or thresholds it used to make its decisions. As for the differences among state modeling procedures, the cost-per-deciview criterion we have suggested is simply the estimated cost divided by the estimated improvement—how that value is derived is irrelevant in this context—it is how the value is used that matters.

DOI Comment 13: For several units, NDDOH is proposing alternative sulfur dioxide (SO_2) limits that are similar to the presumptive BART limits because they allow a source to choose between a limit in terms of pounds of emissions per million Btu of heat input, or percent reduction of that pollutant. While EPA presented its BART Guidelines for SO_2 in that format, we do not believe that it was EPA's intention to allow the source to choose the more favorable limit. By definition, BART represents the highest degree of control that meets the five-factor test. Where NDDOH has determined that a lb/mmBtu limit is reasonable, it should require that that limit be met.

Similarly, where NDDOH has determined that a percent reduction limit is reasonable, it should require that that limit be met. If both limits are determined to be reasonable, then to allow the source to choose only one clearly does not represent the most stringent reasonable degree of control. Therefore, where NDDOH has proposed alternative limits, both should be required.

NDDH Response: The DOI has requested that the sulfur dioxide limitations be written as 95% reduction and 0.15 lb/10^6 Btu instead of 95% reduction or 0.15 lb/10^6 Btu. Coal quality data suggests that the source may not be able to comply with the 0.15 lb/10^6 Btu limit when the maximum sulfur coal is received. This would make the requested standard impossible to meet for high sulfur coal. The BART guidelines (40 CFR 51, Appendix Y, Section IV.E.4) states "you must require 750 MW power plants to meet specified levels of SO_2 of either 95 percent control or [emphasis added] 0.15 lb/10^6 Btu". The guidance does not indicate both standards apply. In addition, the BART presumptive levels are not applicable to any source in North Dakota except for NO_x at Coal Creek Station.

DOI Follow-up: There is also a fundamental problem with setting only a percent-reduction limit on SO_2 emissions. If fuel sulfur content increases, emissions can increase correspondingly. Unless sulfur content is limited, or a cap is placed on mass emissions (e.g., lb/hr, tons/yr as proposed by Wyoming, for example), the actual amount of SO_2 emitted is unlimited.

NDDH Response: The DOI has also asked that a mass per unit of time limit be placed on the permit for SO_2. The Department believes this is unnecessary since the Department's evaluation of visibility impacts was based on full load and worst case sulfur (i.e. highest 24-hour emissions). The Department asked the EPA if a mass per unit of time limit (24-hour basis to ensure the accuracy of the modeling) was necessary in the permit that establishes the BART limits. In a November 21, 2005 response from Laurel Dygowski of Region 8, it was stated "we think that a 24-hour limit is unnecessary and may not be of much value". Based on EPA's guidance and the Department's determination that mass per unit of time units are not necessary, the Department will not include such limits in the permit that establishes the BART limits.

DOI Follow-up: As we noted previously, even if coal quality deteriorates to the anticipated worst-case, the proposed control technology would still be capable of meeting the lower lb/mmBtu limit.

DOI Comment 25: On page 16 of the comments, the DOI states, "We believe that higher control efficiency is warranted for both the lignite and PRB sub-bituminous scenarios". The DOI goes on to state that a facility burning coal with an uncontrolled SO_2 emission rate of 2.4 lb/MM Btu for lignite and 1.6 lb/MMBtu on PRB "should be capable of at least 93% control and achieve an emission limit of 0.09 lb/MMBtu on a 30-day rolling average basis[11]". Footnote 11 in the DOI comments states, "Please see the entry in Appendix D for the permit issued by Wyoming to Black Hills Power for its WYGEN3 project".

NDDH Response: The DOI states a SD/FF at Stanton #1 "should be capable of" at least 93% control and an emission limit of 0.09 lb/MMBtu on a 30-day rolling average basis. The DOI attempts to support this position by referencing the WYGEN3 facility permit. Although the WYGEN3 facility does have a 0.09 lb/MMBtu SO_2 emission limit, according to the EPA RACT/BACT/LAER clearinghouse, the 0.09 lb/MM Btu SO_2 emission limit is on a 12-month rolling average basis, not a 30-day rolling average basis. Also, the RACT/BACT/LAER clearinghouse does not list a required SO2 removal efficiency. If the WYGEN3 facility burns low-sulfur coal, the facility could comply with the 0.09 lb/MMBtu emission limit with SO_2 control efficiencies below 90%. Furthermore, it is the Department's understanding that the WYGEN3 facility has yet to operate and demonstrate that the SO_2 emission limit can be achieved. Based upon these facts, the WYGEN3 facility permit does not support the DOI position that a SD/FF at Stanton Station Unit 1 "should be capable of" at least 93% control and an emission limit of 0.09 lb/MMBtu on a 30-day rolling average basis. The Department maintains the position that a SD/FF operating at Stanton Station Unit 1 is capable of achieving an SO_2 control efficiency of 90%.

DOI Follow-up: The WYGEN3 permit[1] limits the EGU to 117 lbSO_2/hr on a 30-day rolling average basis. At a heat input of 1,300 mmBtu/hr, this corresponds to 0.09 lb SO_2/mmBtu on a 30-day rolling average.

DOI Comment 26: On page 16 of the DOI comments, the DOI states, "Because the larger Stanton Unit #10 also located at this site is achieving less than 0.06 lb/MMBtu on an annual basis (presumably burning PRB coal) using the same SD/FF technology proposed for Stanton Unit #1, NDDAQ should explain why a newer installation of that technology at Stanton #1 cannot perform as well, at least on PRB coal".

NDDH Response: The DOI incorrectly states that Stanton #10 is larger than Stanton #1. In fact, Stanton #10 (with a heat input of approximately 642 MM Btu/hr) is approximately 2.8 times smaller than Stanton #1 (with a heat input of approximately 1,800 MM Btu/hr). The DOI states that Stanton #10 emitted SO_2 at an emission rate of 0.06 lb/MM Btu and asks the Department to explain why Stanton #1 cannot perform as well as Stanton #10 when burning PRB coal. Although the Stanton #10 facility has recently emitted SO_2 at an emission rate of 0.06 lb/MM Btu, based upon the average sulfur content of the coal burned the SO_2 removal efficiency at Stanton #10 is estimated to be approximately 90%. The dry scrubber technology proposed as BART for Stanton #1 is expected to achieve an SO_2 control efficiency of 90%, so Stanton #1 will be expected to perform as well as Stanton #10.

DOI Follow-up: We appreciate NDDH's correction of our error with respect to the relative sizes of the two EGUs. However, this does not change our contention that Stanton #1 should be able to perform as well as Stanton #10, both on lb/MMBtu and control efficiency bases. NDDH should show how it arrived at the conclusion that "based upon the average sulfur content of the coal burned the SO_2 removal efficiency at Stanton #10 is estimated to be approximately 90%."

DOI Comment 29: On page 17, the DOI states, "We believe that NDDAQ should have included SOFA with tail-end SCR with reheat in its analysis".

NDDH Response: The Department analyzed SCR with reheat in the BART analysis. A 90% control efficiency for SCR with reheat was assumed. For retrofits, the Department believes that a 90% control efficiency for SCR with reheat is highly optimistic and that 80% control is

---

[1] http://deq.state.wy.us/eqc/orders/Air%20Closed%20Cases/07-2801%20Dry%20Fork%20Station/DEQ's%20Dispositive%20Response.63-Ex.16.pdf

reasonable. It should be noted that conducting the BART analysis using an 80% control efficiency would make the cost of SCR with reheat even more cost prohibitive.

In the Department's judgment, SOFA with SCR with reheat would not attain greater than 90% NO_x control at Stanton #1. Since SOFA with SCR with reheat would be more expensive than SCR with reheat (which has already been determined to be cost prohibitive assuming a 90% control efficiency), it can be concluded that an analysis of SOFA with SCR with reheat would also be considered to be cost prohibitive.

DOI Follow-up: NDDH cannot assume that "SOFA with SCR with reheat would be more expensive than SCR with reheat" on a total annual cost basis without doing a proper cost analysis. It is possible that the additional capital cost (on an annual basis) of adding SOFA would be more than offset by reduced annual operating costs.

DOI Comment 30: On pages 18 and 20 the DOI indicates that the expected costs for SCR with reheat included in the BART analysis for Stanton #1 are higher than the cost estimates prepared by the DOI. The DOI requests that NDDH document and justify the SCR-with-reheat cost estimate.

NDDH Response: The DOI requests that the Department document and justify the SCR with reheat cost estimate for Stanton #1. The Department considers the cost estimate of SCR with reheat submitted with the GRE BART analysis to be extensively documented and the Department has verified the cost estimates.

DOI Follow-up: NDDH should explain how it "verified the cost estimates".

DOI Comment 34: DOI believes SOFA + SCR can achieve 83% NO_x removal.

NDDH Response: As pointed out in the Advanced Notice of Proposed Rulemaking for the Four Corners Power Plant, the Arizona DEQ determined that 75% control was appropriate following low NO_x burners at the Coronado Generating Station. Leland Olds 1 is equipped with low NO_x burners. We believe 75% reduction for the retrofit of a 43 year old plant is appropriate. Reducing the emission rate to 0.05 $lb/10_6$ Btu achieves 212 tons per year additional NO_x reduction. The cost effectiveness is then $8,888/ton to $12,784/ton. These costs are still considered excessive and SCR + SOFA is not BART.

DOI Follow-up: We have advised EPA Region 9 that it has underestimated the ability of SCR to reduce NO_x emissions from the sources in question and supported our comments with real-world data from actual retrofits to coal-fired EGUs. Our comments can be found in the same docket accessed by NDDH. Furthermore, NDDH cannot simply halt the BART

process by determining that a technically feasible option is too expensive on a cost-per-ton basis. A full five-factor BART analysis is required.

DOI Comment 35: NDDAQ did not evaluate the visibility benefits of any of the technically feasible options except for the proposed basic SOFA + SCR.

NDDH Response: The cost analysis eliminated SCR, coal reburn + SCR, coal reburn + SOFA and SNCR + boosted SOFA on either a very high cost effectiveness basis or a very high incremental cost basis. This left SOFA + SNCR as the most efficient control option. This option was then modeled to determine the visibility effects.

DOI Follow-up: NDDH cannot simply halt the BART process by determining that a technically feasible option is too expensive on a cost-per-ton basis. A full five-factor BART analysis is required.

DOI Comment 37: Based upon NDDAQ's analysis, addition of the proposed basic SOFA+SNCR to LOS #1 yields a cost-effectiveness of $25.6 million per dv at Theodore Roosevelt NP and $13.2 million per dv cumulatively when Lostwood WA is included. NDDAQ has not adequately considered the visibility benefits of the control strategies it evaluated. NPS' analysis of addition of basic SOFA+SCR with reheat yields a cost-effectiveness of $12.6 – $32.3 million per dv cumulatively. We would normally consider costs above $20 million/dv to be above the average that most states/source are proposing, but believe that these results warrant further analysis, as we will discuss in more detail with respect to LOS #2.

NDDH Response: SOFA + SCR has an estimated cost of $8,888 - $12,784/ton of NO_x removed. The incremental cost would be approximately $15,748/ton to $25,319/ton over the next most efficient option. It is clear that SOFA + SCR, or SCR alone, is not cost effective for this unit.

DOI Follow-up: NDDH cannot simply halt the BART process by determining that a technically feasible option is too expensive on a cost-per-ton basis. A full five-factor BART analysis is required.

M.R. Young Station Unit 1

DOI Comment 49: NDDAQ proposes that NO_x emissions be limited to 2,070.2 lb/hr on a 24-hour rolling average basis during startup. We recommend that NDDAQ limit the mass emission rate (e.g., lb/hr) to the rate under normal operation.

NDDH Response: The proposed limit is under normal operating conditions without the ASOFA and SNCR, since the SNCR cannot be operated until the proper boiler temperature is reached. The actual startup emissions will be much higher (>1.0 lb/10^6 Btu). Therefore, limiting startup emissions based on normal operations with SNCR (<0.35 lb/10^6 Btu) will provide no relief to the source during startup.

DOI Follow-up: To clarify our initial comment, we are suggesting that NDDH limit emissions on a lb/hr basis (not lb/mmBtu) to a rate equal to the maximum lb/hr that would be allowed were MRYS #1 to meet its BART limit under normal operation (e.g., BART limit in lb/mmBtu * maximum allowable heat input in mmBtu/hr). Thus, as load (and furnace temperature) increases, the effectiveness of the NO_x control technology also increases so as to stay under the lb/hr limit.

DOI Comment 51: NDDAQ overestimated the costs associated with adding SCR. In the absence of supporting documentation by NDDAQ, we also estimated a total annual cost for ASOFA + SCR with reheat at $9.7 million and a corresponding cost effectiveness of $1,028 per ton.

NDDH Response: Minnkota has provided its own estimate of the cost of SCR as part of the BACT process under their Consent Decree. Minnkota's estimate has been included in the BART determination.

DOI Response: We have not had sufficient time to properly evaluate the materials posted on or after November 25, 2009, by NDDH.

<u>M.R. Young Station Unit 2</u>

DOI Comment 54: NDDAQ proposes that NO_x emissions be limited to 3,995.6 lb/hr on a 24-hour rolling average basis during startup. We recommend that NDDAQ limit the mass emission rate (e.g., lb/hr) to the rate under normal operation.

NDDH Response: See response to Comment 49.

DOI Follow-up: To clarify our initial comment, we are suggesting that NDDH limit emissions on a lb/hr basis (not lb/mmBtu) to a rate equal to the maximum lb/hr that would be allowed were MRYS #2 to meet its BART limit under normal operation (e.g., BART limit in lb/mmBtu * maximum allowable heat input in mmBtu/hr). Thus, as load (and furnace temperature) increases, the effectiveness of the NO_x control technology also increases so as to stay under the lb/hr limit.

DOI Comment 56: NDDAQ overestimated the costs associated with adding SCR. In the absence of supporting documentation by NDDAQ, we estimated total annual costs for ASOFA+tail-end SCR with reheat at $15.6 million and a corresponding cost effectiveness of $898 per ton.

NDDH Response: Minnkota has provided a much more detailed cost estimate of SCR with reheat as part of their BACT process under their Consent Decree. This estimate has been used in the Department's BART determination.

DOI Follow-up: We have not had sufficient time to properly evaluate the materials posted on or after November 25, 2009, by NDDH.

DOI Comment 63: Table 9.9 summarizes the results of assessing the costs and visibility improvement associated with possible controls on these facilities. The two power generation facilities, Coyote and AVS, have emissions and Q/d impacts that are similar, if not greater than, BART sources that will be required to add controls. The methodology to calculate visibility improvements noted in Table 9.9 are not explained in this section but appear to be some calculation of changes in the long-term metric of the 20 percent worst visibility days. These sources likely contribute to higher impacts on a daily basis, and a reduction in their emissions would be part of a broad strategy to reach natural conditions at the Class I areas. As such NDDAQ should examine the total improvement from the suite of sources as part of its reasonable progress assessment, not a simple unit by unit approach.

NDDH Response: The improvement in the 20% worst days was used to indicate the amount of visibility improvement. The SIP was revised to better explain this. Addressing individual days under reasonable progress is inconsistent with the reasonable progress goals in 40 CFR 51.308(d)(1) which states "The reasonable progress goals must provide for improvement in visibility for the most impaired days over the period of the implementation plan and ensure no degradation in visibility for the least impaired days over the same period." 40 CFR 51.301 defines the most impaired days as meaning "the average visibility impairment (measured in deciviews) for the 20% of monitored days in a calendar year with the highest amount of visibility impairment." 40 CFR 51.301 defines the least impaired days as the average visibility impairment (measured in deciviews) for the 20% of monitored days in a calendar year with the lowest amount of visibility impairment." It is clear that reasonable progress goals should be established based on the average of the "most impaired days" and the "least impaired day", not individual days.

The Department did evaluate the cumulative effects of the most efficient remaining options. As stated on p. 182, the cumulative visibility improvement was 0.11 deciviews at LWA and 0.03 deciviews at TRNP. The less efficient control options would provide even less improvement.

DOI Follow-up: The use of daily impacts is a good means to identify those sources that have the largest impact on the 20 percent worst days. Since North Dakota is not meeting the uniform rate of progress for visibility improvement under EPA's guidance, it should seriously evaluate all significant sources of human-caused impairment. It is unclear if cumulative visibility improvement cited in the SIP included controls at Coyote and AVS.

Basin Electric Power Cooperative

Comment 1: Basin Electric believes LDSCR and TESCR are not technically feasible. They believe the Department should not rely on historical operating data of biomass boilers and should not rely on vendor's statements that they will provide performance guarantees for LDSCR and TESCR. Basin Electric believes LDSCR and TESCR are not commercially available for boilers that combust North Dakota lignite.

Response: The Department's analysis of this issue indicates that electrostatic precipitators, such as those at the Leland Olds Station, are capable of removing up to 99% of the sodium that is in the lignite combusted. The analysis also indicates that control of the submicron sodium and potassium aerosols will be greater than 90%. This indicates the flue gas characteristics will be no worse than cyclone boilers burning subbituminous coal in a high dust SCR configuration. It also indicates the concentration of potassium and sodium aerosols are less than pilot scale testing for biomass combustion which indicates an SCR can be successfully operated (Zheng et. al. 2008, Kling et. al. 2007). The commenter provided no evidence to dispute this point. Biomass contains soluble sodium and potassium just like North Dakota lignite. TESCR is being operated successfully on several biomass boilers.

Regarding vendor guarantees, the BART Guideline states "Vendor guarantees may provide an indication of commercial availability and the technical feasibility of a control technique and could contribute to a determination of technical feasibility or technical infeasibility, depending on circumstances. However, we do not consider a vendor guarantee alone to be sufficient justification that a control option will work. Conversely, lack of a vendor guarantee by itself does not present sufficient justification that a control option or an emissions limit is technically infeasible. Generally, you should make decisions, about technical feasibility based on chemical, and engineering analyses (as discussed above), in conjunction with information about vendor guarantees." The information on vendor guarantees was only one portion of the evidence that was considered in making the technical feasibility determination. The commenter also suggested that pilot scale testing is necessary before LDSCR and TESCR can be determined to be technically feasible. The flue gas characteristics after an ESP when compared to pilot testing at biomass-fired boilers (Zheng et. al. and Kling et. al.) indicate LDSCR and TESCR can be successfully operated on North Dakota lignite. Pilot testing will help optimize the design of LDSCR or TESCR and provide a better estimate of catalyst life; however, the NDDH believes it is unnecessary for determining technical feasibility.

Comment 2: The commenter believes that BART NO_x controls that have a cost effectiveness greater than $1,350 per ton are unreasonable.

Response: The EPA has not established a "bright line" for determining whether BART controls are cost effective or reasonable. In the preamble to the proposed BART Guideline (F.R. Vol. 69, No. 87, p. 25198) EPA discussed this issue. This discussion indicates the WRAP technical support document for the Grand Canyon visibility Transport Report Annex listed control options are "low" below $500 per ton, "moderate" from $500 per ton to $3,000 per ton and "high" if over $3,000 per ton. This is a 1999 document and costs must be adjusted accordingly for inflation. The CAIR rule, which could have been used as a substitute for BART, had an estimated cost of up to $2,700 per ton (this rule has now been vacated). Based on the information cited, the NDDH believes the $1,350 per ton cost effectiveness is a reasonable BART cost.

Comment 3: The Department's conclusion (in the SIP), that the elimination of every in-state emissions source would still not achieve the 2018 reasonable progress (glide path) goal, is counterintuitive and is misleading on several fronts.

Response: Because the commenter provided no specific information on why this conclusion is "counterintuitive or misleading," the Department cannot directly respond. However, the Department believes that the modeling analysis supporting this conclusion makes a very strong and intuitive point about the relatively low contribution of North Dakota visibility-affecting emissions sources to visibility degradation in North Dakota Class I areas. Therefore, the Department stands by the conclusion.

Basin Electric, Great River Energy and Minnkota Power Coop.

Comment 1: The commenters want the SIP revised to redefine natural visibility conditions and reset the glide path for reasonable progress goals.

Response: For the current planning period and SIP, the Department does not have the time or resources to adjust natural visibility conditions and reset the uniform rate of progress glide path as suggested. However, the Department finds merit in this suggestion and will consider such adjustments in the next planning period.

Great River Energy

Comment 1: GRE agreed with the NDDH's modeling approach and encouraged the NDDH to use the most up-to-date modeling science and to calibrate these models with actual monitored data to ensure their relative accuracy.

Response: Agreed

Comment 2: GRE believes the NDDH must preserve its ability to adjust the glide path for non-manmade and international emissions.

Response: See response to Comment No. 1 under Basin Electric, Great River Energy and Minnkota Power Coop.

Comment 3:

(a) GRE believes site specific cost estimates provided by various consulting firms are more accurate than from cost manuals which are adjusted for inflation.

Response: Agreed

(b) GRE believes that approximately $1,000 per ton cost effectiveness should be used as a cutoff for BART determinations.

Response: See response to Basin Electric’s Comment No. 2.

RE: Basin Electric Power Cooperative Comments on proposed Amendments to the State Implementation Plan for Air Pollution Control relating to the Reduction of Regional Haze

Dear Mr. O'Clair:

Basin Electric Power Cooperative (Basin Electric) appreciates this opportunity to offer comments on the proposed Amendments to the State Implementation Plan for Air Pollution Control relating to the Reduction of Regional Haze. Basin Electric agrees, in general, with your individual BART Determination for our two generating units at the Leland Olds Facility. We also support the Department's determination of technical infeasibility relating to High-Dust Selective Catalytic Reduction (SCR) as applied to cyclone boilers combusting North Dakota Lignite.

We do, however, believe that the Department is in error in its applicability determination that Low-Dust and TE SCRs are technically feasible for reduction of Nitrogen oxides (NOx) from a cyclone boiler firing North Dakota Lignite. The determination was seemingly based on transference of historical operating data of biomass fired boilers whose boiler type, size, and flue gas properties do not represent a similar enough application to justify its extension to North Dakota Lignite-fired cyclone boilers. Most concerning was a reliance on vendor statements alleging their willingness to consider offering guarantees of NOx reduction performance outside the framework of binding contractual obligations to back up these statements, or evidence that these promises of potential guarantees had any guaranteed performance levels that would make them meaningful. This sets a dangerous precedent of vendor puffing serving as a basis for claiming commercial availability. The clear path forward was to do the needed pilot testing, and then base the determination on this actual performance testing in future phases of the regional haze program. EPA guidance is clear that when pilot testing is needed, the application is not commercially available. When this bright-line test is ignored, where the line is drawn becomes arbitrary and unsupportable. When a decision has hundreds of millions of dollars of potential impacts on electrical customers throughout the Midwest, the evidence supporting commercial availability needs to be placed on a firmer technical, legal and factual foundation. Although we agree with your determination that Low-Dust and TE SCRs are not economically feasible, we ask you to re-consider your determination that Low-Dust and TE SCRs are commercially available for high-sodium-lignite cyclone boilers.

Sargent and Lundy (S&L) is an independent engineering and construction management service organization who has been a leader in the design, construction, and operation of selective catalytic reduction within the energy industry. Furthermore, S&L has participated in the development of the only two tail-end configured SCRs on coal-fired boilers in the United States. S&L provided significant input as to what is known and what is unknown from their previous experience of SCR design on Texas Lignite, Sub-bituminous, and Bituminous fired boilers. S&L presented extensive evidence showing that pilot testing is required to design Low and Tail-end SCR systems for several reasons, including that the chemical and physical properties of the flue gas from combusting North Dakota Lignite in a cyclone boiler is unique and not well enough understood—based on S&L's previous experiences of SCR applications—to make it a commercially available technology.

The cost of this pilot testing is estimated to be $1.5 to 2.0 million and would take 18 to 24 months to complete. This need for pilot testing provides, under EPA guidance, the bright-line test that demonstrates that Low-Dust and Tail-end configured SCR are not a commercially available technology for high-sodium-lignite burning cyclone boilers. We are disappointed that EPA continues to encourage you to ignore EPA's own bright-line test; Low-Dust and TE SCRs require pilot testing before they can be applied to high-sodium-lignite-burning cyclones, which precludes a determination that those applications are commercially available under any reasonable interpretation of EPA's own guidance.

The NDDH requested that Basin Electric prepare a cost effectiveness determination for a Tail-End SCR application. As explained previously, it is impractical to provide a definitive cost determination for a Tail End SCR application without completing the additional testing described above. In May 2009, at the NDDH's request, a hypothetical cost effectiveness determination as developed by S&L and submitted to the Department. Hypothetical cost effectiveness were developed under five various scenarios of various catalyst life, and other input costs, i.e. natural gas, ammonia and subsequent sorbent control. The hypothetical cost effectiveness ranged from a low of $4,170 per ton up to $5,976 per ton.

The hypothetical cost effectiveness determination as determined by S&L should then be compared to the NOx control and cost impact data published by EPA as part of the Regional Haze Rule rulemaking process, including EPA's "Technical Support Document – Methodology for Developing BART NOx Presumptive Limits" (EPA Clean Markets Division, June 15, 2005). This review would indicate that EPA established the presumptive BART limits under the Regional Haze Rule of $1,350 per ton as being cost effective for all boilers other than cyclones while control technologies that had a cost impact greater than $1,350 were not cost effective. SCR were determined to be cost effective on Cyclone Boilers. The average cost effectiveness of SCR on Cyclone Boilers was determined to be $901per ton.

Attached for your consideration is S&L's report of this regulatory evaluation. The estimated cost effectiveness of $4,170 to $5,976 per ton for Tail End SCR on a cyclone boiler is significantly higher than EPA established reasonable cost threshold for NOx Controls under BART of $1,350 per ton.

Basin Electric also suggests that the Department revise what is defined as the natural background visibility and then re-setting the glide path for reasonable progress. Emission sources that are beyond the control of the Department (international point sources and particulate matter such as windblown dust and wildfires) should be removed from the reasonable progress determination. Multiple significant modeling efforts have been completed for North Dakota Class I areas that indicate the significant role the international source and the non-point source particulate matter. The conclusion that with the elimination of every in-state emissions would still not achieve the 2018 reasonable progress goal is counterintuitive and is misleading on several fronts. This discussion (Jan 2010) was submitted collaboratively to the Department under separate cover by Great River Energy, Minnkota Power Cooperative and Basin Electric Power Cooperative.

Basin Electric has now completed most of the construction of its new sulfur dioxide scrubber for its Leland Olds station several years before when construction would have commenced if Basin Electric had waited for the NDDH's BART determination. A couple months ago, the NDDH asked if Basin Electric would consider offering further early action under Reasonable Progress for non-BART-eligible sources in North Dakota. This request came too late for Basin Electric to advance it to its management and board. This does not preclude consideration of this possibility at some point in the future.

Sincerely,

Cris Miller

Project: Basin Electric Power Cooperative – Leland Olds Station
Subject: BART Cost Effectiveness Thresholds

Dear Mr. Miller:

The purpose of this letter report is to present the U.S. Environmental Projection Agency's (EPA's) determination of cost-effectiveness thresholds for retrofit emission control technologies under the Regional Haze Rule.[1] Basin Electric Power Cooperative asked Sargent & Lundy (S&L) to perform this evaluation to supplement the Best Available Retrofit Technology Determination prepared for Leland Olds Station Units 1 and 2, and submitted to the North Dakota Department of Health (NDDH) in August 2006.

S&L provides comprehensive consulting, engineering, design, and analysis for electric power generation and power delivery projects throughout the U.S., and we are very familiar with all of the major environmental rules regulating emissions from electric generating units, including the Regional Haze Rule. We are experienced with all aspects of air pollution control, and have prepared a number of control technology evaluations, cost-estimates, and cost-effectiveness evaluations for electric generating units. To complete this analysis, we reviewed nitrogen oxide (NOx) control and cost impact data published by EPA as part of the Regional Haze Rule rulemaking process, including EPA's "Technical Support Document for BART NOx Limits for Electric Generating Units Excel Spreadsheet" and "Technical Support Document – Methodology for Developing BART NOx Presumptive Limits" (EPA Clean Air Markets Division, June 15, 2005).

---

[1] The Regional Haze Rule was published on July 6, 2005, "Regional Haze Regulations and Guidelines for Best Available Retrofit Technology Determinations," 70 FR 39104. Unless otherwise noted, all references to EPA's Regional Haze Rule in this document mean the preamble and rule published on July 6, 2005.

Based on our review of the cost impact evaluation prepared by EPA to establish the presumptive BART limits under the Regional Haze Rule, it can be concluded that a threshold of $1,350/ton should be used to establish the cost-effectiveness of NOx retrofit controls. In general, EPA concluded that NOx control technologies that had a cost impact of less than $1,350/ton were cost-effective (e.g., combustion controls on all boiler types other than cyclones), while control technologies that had a cost impact greater than $1,350 were not cost-effective (e.g., SCR on all boiler types other than cyclones).

Background

Basin Electric Power Cooperative's (BEPC's) Leland Olds Station (LOS) Unit 2 is a B&W cyclone-fired unit with a turbine-generator nameplate rating of 440 MW. The unit was identified by NDDH as a BART-eligible source under the Regional Haze Rule. As such, BEPC is required to control emissions from LOS Unit 2 using Best Available Retrofit Technology (or "BART"). In August 2006, BEPC submitted its BART evaluation for the Leland Olds Station, including an evaluation of NOx emission controls on LOS Unit 2 (the "BART Determination Study"). The BART Determination Study concluded that selective non-catalytic reduction (SNCR) with advanced separated overfire air (ASOFA) represented BART for NOx control on LOS Unit 2, and proposed a BART NOx emission limit of 0.35 lb/mmBtu (30-day rolling average).

Tail-end selective catalytic reduction (TE-SCR) was identified in the BART Determination Study as a potentially available post-combustion NOx retrofit control technology for LOS Unit 2. However, the study determined that TE-SCR would be susceptible to unacceptable catalyst deactivation from soluble alkalis in the unit's lignite fuel (most notably sodium). The study concluded that TE-SCR was not a technically feasible NOx retrofit control technology due to the flue gas characteristics associated with the North Dakota lignite fired in LOS Unit 2.

Subsequently, NDDE requested additional analysis of the cost effectiveness of the TE-SCR technology assuming the technology was determined to be technically feasible and commercially available. In response to the Department's request, BEPC submitted a cost effectiveness evaluation of the TE-SCR on LOS Unit 2. That evaluation, dated May 27, 2009, calculated a cost effectiveness for TE-SCR (assuming technical feasibility) to be in the range of $4,170 and $5,976/ton depending on the rate of catalyst degredation and the cost of consumables (ammonia and natural gas). This letter report reviews the economic impact evaluation prepared by EPA to support the final Regional Haze Rule, which established a cost-effectiveness threshold for retrofit control technologies.

BART Cost Effectiveness

The Regional Haze Rule requires that a determination of BART must be based on an analysis of the best system of continuous emission control technology available and associated emission reductions achievable, taking into consideration: (1) the technology available; (2) the costs of compliance; (3) the energy and non-air-quality environmental impacts of compliance; (4) any pollution control equipment in use at the source; (5) the remaining useful life of the source; and (6) the degree of improvement in visibility which may reasonably be anticipated to result from the use of such technology.[2] BART is determined on a case-by-case basis. Guidelines for making BART determinations are included in Appendix Y of 40 CFR Part 51 (Guidelines for BART Determinations Under the Regional Haze Rule). The Appendix Y guidelines for BART determinations identify the following five steps in a case-by-case BART analysis:

Step 1. Identify All Available Retrofit Control Technologies.
Step 2. Eliminate Technically Infeasible Options.
Step 3. Evaluate Control Effectiveness of Remaining Control Technologies.
Step 4. Evaluate Impacts and Document the Results.
Step 5. Evaluate Visibility Impacts.

Step 4 of the BART determination process involves an evaluation of potential impacts associated with the technically feasible retrofit technologies. Impact evaluations should be conducted to assess: (1) costs of compliance; (2) energy impacts; and (3) non-air quality environmental impacts. The economic analysis performed in Step 4 of the BART determination examines the cost-effectiveness of each control technology, on a dollar-per-ton of pollutant removed basis. Annual emissions using a particular control device are subtracted from baseline emissions to calculate tons of pollutant controlled per year. Annual costs are calculated by adding annual operating and maintenance (O&M) costs to the annualized capital cost of an option. Cost effectiveness of an option is simply the annual cost ($/yr) divided by the annual pollution controlled (ton/yr).

Presumptive BART Limits

In the Regional Haze Rule EPA established presumptive BART emission limits for SO_2 and NOx for certain electric generating units (EGUs) based on fuel type, unit size, cost effectiveness, and the presence or absence of pre-existing controls.[3] The presumptive levels were intended to reflect "highly cost-effective technologies," while providing flexibility to States to consider source specific characteristics when evaluating BART.

[3] See, 40 CFR 51 Appendix Y Part IV, and 70 FR 39131.

Methodology for Developing BART NOx Presumptive Limits

To develop the presumptive BART NOx limits, EPA analyzed costs and emission reductions associated with the installation of various NOx control systems at BART-eligible EGUs including combustion control and post-combustion control systems. A detailed cost impact evaluation was developed using different combinations of boiler design, fuel, and control technology. Results of the NOx cost impact evaluation, including control costs and controlled NOx emission rates used in the evaluation, are presented in EPA's "Technical Support Document for BART NOx Limits for Electric Generating Units Excel Spreadsheet" ("BART Excel Spreadsheet"). The methodology used by EPA to prepare the BART Excel Spreadsheet is described in EPA's "Technical Support Document – Methodology for Developing BART NOx Presumptive Limits" (EPA Clean Air Markets Division, June 15, 2005).

The cost-effectiveness of each retrofit technology was calculated based on: (1) capital cost ($/kW); (2) fixed O&M ($/kW); (3) variable O&M (mills/kW-hr); and (4) controlled NOx emissions (lb/mmBtu). Capital and fixed O&M costs were adjusted based on boiler capacity to account for economies-of-scale achievable with larger units. Variable O&M costs were calculated using each individual units' baseline heat input to account for individual capacity factors. Costs were developed for bituminous, lignite and subbituminous-fired units for the following five boiler configurations: (1) Cyclones; (2) Cell Burners; (3) Dry-Bottom (DB) Wall-Fired; (4) DB Turbo-Fired; and (5) Tangentially (T) Fired units.[4]

Three coal-fired control cases were used by EPA to evaluate the cost-effectiveness of combustion and post-combustion NOx control technologies on coal-fired EGUs. A description of the three control cases, designated as Cases 1a, 1d, and 1e, is provided in Table 1.

---

[4] EPA also prepared cost effectiveness calculations Stoker, Wet-Bottom, and "Other" boiler configurations; however, because of the limited number of boilers in each of those groups (5, 6, and 1, respectively) those boilers have not been included in this summary.

Table 1
BART Cost-Effectiveness Evaluation
Coal-Fired EGU Control Cases

Control Case	Control Action Taken	Major Assumptions/Notes
1a	Installation of current NOx combustion controls for unit with no prior controls, or which had controls installed before 1997. For unit with controls installed in or after 1997, install incremental controls if a complete set of combustion controls was not installed (low NOx Burners and Overfire Air). For Cyclone units, apply coal reburn if no prior controls installed. For Cell Burners, install current combustion controls if the unit had no controls or controls were installed before 1997. Do not include existing SCR or SNCR units in the Control Case NOx Rate.	If the 2004 NOx rate was less than the floor rate established for each NOx control technology, no controls added. Used average heat input from 2002 – 2004 to calculate an Average NOx Rate. Assumed 10,000 Btu/kWh heat rate for coal-fired boilers.
1d	Install SCR, unless unit already has SCR installed or the 2004 NOx rate is already at or below the SCR floor rate.	
1e	Install rotating overfire air (ROFA) unless unit already has SCR or the 2004 NOx Rate is already at or below the ROFA floor rate, or the calculated ROFA rate is greater than or equal to the 2004 NOx rate. Also, for Cyclone boilers install SCR. Do not include units with existing SCR/SNCR in the Control Case NOx rate.	

Presumptive NOx BART Limits

For all types of boilers, other than cyclone units and units already equipped with post-combustion controls (i.e., SCR and SNCR), the NOx presumptive BART limits were based on the use of current combustion control technologies. EPA established the presumptive BART levels for each subcategory based on control strategies determined to be generally cost-effective for all units within the subcategory.[5] For sources without post-combustion controls EPA established a presumption as to the appropriate BART limits based on boiler design, coal type, and combustion controls. The BART NOx presumptive emission limits are summarized in Table 2.

---

[5] See, 70 FR 39134 col. 2.

Table 2
Presumptive NOx Emission Limits for BART-Eligible Coal-Fired Units*

Unit Type	Coal Type	Presumptive NOx Limit
Dry-Bottom Wall-Fired	Bituminous Subbituminous Lignite	0.39 0.23 0.29
Tangential Fired	Bituminous Subbituminous Lignite	0.28 0.15 0.17
Cell Burners	Bituminous Subbituminous	0.40 0.45
Dry-Turbo-Fired	Bituminous Subbituminous	0.32 0.23
Wet-Bottom Tangential-Fired	Bituminous	0.62
Cyclone Boilers	All	0.10

* 70 FR 39135 Table 2.

Presumptive BART Cost-Effectiveness

EPA developed the presumptive NOx BART limits listed in Table 2 based on an evaluation of the cost-effectiveness of each control technology. A summary of the average cost-effectiveness for each control case (calculated as the total control cost for all units within the subcategory divided by the total annual tons of NOx removed) by boiler type is provided in Table 3.

Table 3
Average Cost Effectiveness of NOx Controls for BART-Eligible Coal-Fired Units by Boiler Type[6]

Boiler Type	Unit Average Cost Per Ton Removed		
	Case 1a	Case 1d	Case 1e
Cyclone – All	$1,330	$901	$901
Cell Burner – All	$1,198	$1,383	$722
DB Wall Fired-All	$723	$1,554	$853
DB Turbo Fired – All	$622	$1,483	$733
T-Fired – All	$376	$2,012	$875

Case 1a = current combustion controls (LNB+OFA for all boiler types) and coal reburn on cyclone boilers.
Case 1d = SCR on all units.
Case 1e = advanced combustion controls (ROFA on all boiler types) and SCR on cyclones.

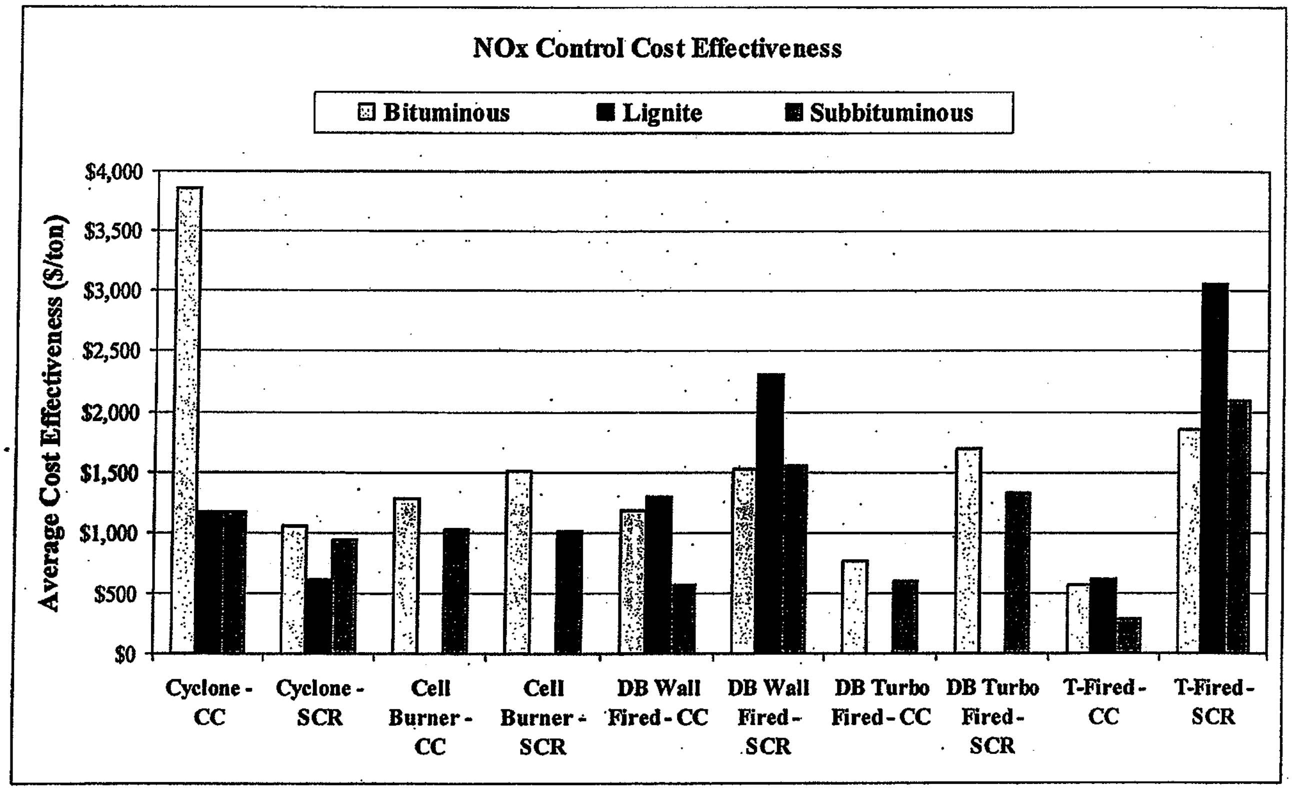
---

[6] See, 70 FR 39135,Table 3. For EGUs currently using post-combustion controls such as SCR or SNCR to reduce NOx during part of the year, EPA established a presumption that use of these same controls year-round is BART. EPA's cost impact assessment showed year-round operation of existing SCRs, compared to operation during the 5-month ozone season only, to be highly cost effective with an average cost-effectiveness of $170/ton (70 FR 39134).

For all the boiler types (except cyclones) the NOx BART limits were based on the use of current combustion control technologies. EPA's cost impact analysis found that combustion controls (Case 1a) were generally, but not always, more cost-effective than post-combustion controls such as SCRs (Case 1d). The cost-effectiveness of combustion control systems (for boiler types other than cyclones) averaged between $376/ton (T-Fired Units) and $1,198/ton (Cell Burners). Combustion controls on Cyclone Boilers (i.e., coal reburn) were determined to be less cost-effective, averaging $1,330/ton removed.

SCR control systems were found to be less cost-effective on all boiler types except Cyclone Boilers. The cost-effectiveness of SCR for all boiler types other than cyclones averaged between $1,383/ton (Cell Burners) and $2,012/ton (T-Fired units). The cost-effectiveness of SCR control on Cyclone Boilers was determined to average $901/ton. The average cost effectiveness of combustion controls and SCR for each boiler type and fuel (i.e., bituminous, lignite, and subbituminous) are shown in Figure 1.

Figure 1
Average Cost Effectiveness of NOx Combustion Controls and SCR



Based on the cost impact results summarized in Figure 1 EPA concluded that combustion controls could cost-effectively reduce NOx emissions on all boiler types other than cyclones, while post-combustion controls, including SCR, were excluded from EPA's presumptive BART determination based on cost impacts.

Cyclone Cost Evaluation

EPA's cost impact evaluation concluded that SCR was more cost-effective than combustion controls on Cyclone Boilers. SCR was determined to be more cost-effective on Cyclone Boilers for several reasons, including: (1) relatively high baseline NOx emission rates; (2) relatively low combustion control efficiencies; (3) high SCR control efficiencies; (4) high combustion control capital costs (compared to combustion controls on other boiler types); and (5) high combustion control O&M costs. Some of the control and cost assumptions used by EPA to develop the BART NOx presumptive limits are summarized in Tables 4 and 5.

Table 4
BART NOx Control Assumptions - Summary

NOx Rate or Control Efficiency	**Unit**	**Boiler Type**				
		Cyclone	**Cell Burner**	**DB Wall-Fired**	**DB Turbo-Fired**	**T-Fired**
Baseline 2004 NOx Rate (units w/o combustion controls)	lb/mmBtu	0.79	0.47	0.40	0.41	0.34
Baseline 2004 NOx Rate (all units)	lb/mmBtu	0.68	0.40	0.37	0.39	0.29
Controlled NOx Rate (combustion controls)	lb/mmBtu	0.47	0.37	0.27	0.22	0.19
Average Combustion Control Efficiency*	%	40.5%	21.2%	32.5%	46.3%	44.1%
Controlled NOx Rate (SCR)	lb/mmBtu	0.073	0.060	0.060	0.060	0.060
Average SCR Control Efficiency**	**%**	**89.3%**	**85.0%**	**83.8%**	**84.6%**	**79.%**

* Average combustion control efficiency was calculated based on the 2004 baseline NOx emission rate associated with units without current combustion controls.

** Average SCR control efficiency was calculated based on the 2004 Baseline NOx emission rate for all units not currently equipped with SCR control.

Table 5
BART Cost Assumptions - Summary

Control Technology	Cost	Unit	Boiler Type				
			Cyclone	Cell Burner	DB Wall-Fired	DB Turbo-Fired	T-Fired
Combustion Controls	Capital Costs	$/kW	$72.66	$23.43	$23.43	$23.43	$14.52
	Fixed O&M	$/kW	$1.10	$0.35	$0.36	$0.36	$0.22
	Variable O&M	mill/kWh	0.26	0.07	0.07	0.07	0.02
	Total Cost	mill/kWh	1.80	0.50	0.47	0.50	0.27
SCR	Capital Costs	$/kW	$100	$100	$100	$100	$100
	Fixed O&M	$/kW	$0.66	$0.66	$0.66	$0.66	$0.66
	Variable O&M	mill/kWh	0.60	0.60	0.60	0.60	0.60
	Total Cost	mill/kWh	2.66	2.41	2.25	2.25	2.18

Based on a review of the control and cost assumptions summarized in Tables 4 and 5, it appears that the most significant variable contributing to the cost effectiveness of SCR on Cyclone Boilers is the relatively high cost of combustion controls. Combustion controls were significantly more expensive on Cyclone Boilers than on other boiler types. Capital costs for combustion controls (i.e., coal reburn) on cyclones averaged $72.66/kW compared to capital costs of $23.43/kW for combustion controls on Cell Burners, DB Wall-Fired, and DB Turbo-Fired units, and $14.52/kW on T-Fired units. Similarly, both fixed and variable O&M costs were significantly higher for Cyclone Boiler combustion controls. As a result, total annual costs for combustion controls on Cyclone Boilers averaged 1.80 mill/kWh, compared to 0.50 mill/kWh for Cell Burners and DB Turbo-Fired units, 0.47 mill/kWh for DB Wall-Fired units and only 0.27 mill/kWh for T-Fired units.

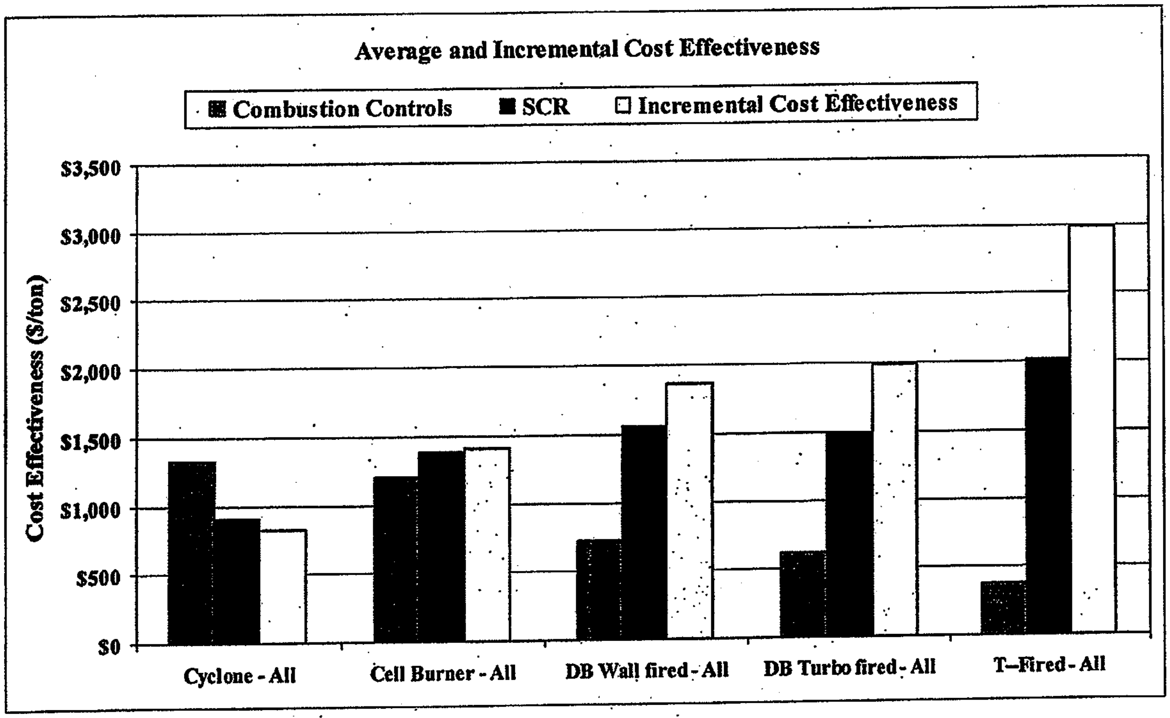
On the other hand, the same cost assumptions were used for SCR retrofit controls regardless of boiler type (i.e., $100/kW Capital Costs-adjusted for boiler size, $0.66/kW Fixed O&M, and 0.60 mill/kWh Variable O&M). Overall annual costs of an SCR system were similar for all boiler types, averaging between 2.18 mill/kWh (T-Fired units) and 2.66 mill/kWh (Cyclone Boilers).

Due to the relatively low control effectiveness and the high cost of combustion controls (including both capital and O&M), combustion controls were determined to be less cost effective on Cyclone Boilers than SCR. SCR control was assumed to achieve significantly lower controlled NOx emissions (0.073 lb/mmBtu compared to 0.47 lb/mmBtu with combustion controls) at a relatively low incremental increase in capital costs ($100/kW compared to $72.66/kW for combustion controls). Based on these assumptions SCR was found to be more cost effective on Cyclone Boilers than combustion controls.

BART Cost Effectiveness Conclusions

Regardless of the assumptions used in the BART cost impact evaluation, EPA concluded that post-combustion controls were not cost effective for all boiler types other than Cyclone Boilers. Thus, the cost effectiveness of SCR controls on those boiler types can be used to determine the cost-effectiveness threshold used by EPA to conclude that post-combustion controls were not cost-effective. In addition to the average cost effectiveness of a control technology (i.e., relative to the base case), the incremental cost-effectiveness to go from one level of control to the next more stringent level of control (i.e., from combustion controls to SCR) may be used to evaluate the cost impact of the more stringent control. Figure 2 summarizes the average cost effectiveness of combustion controls, the average cost effectiveness of SCR, and the incremental cost effectiveness of SCR (compared to combustion controls) for each boiler type

Figure 2
Average and Incremental Cost Effectiveness of NOx Retrofit Controls

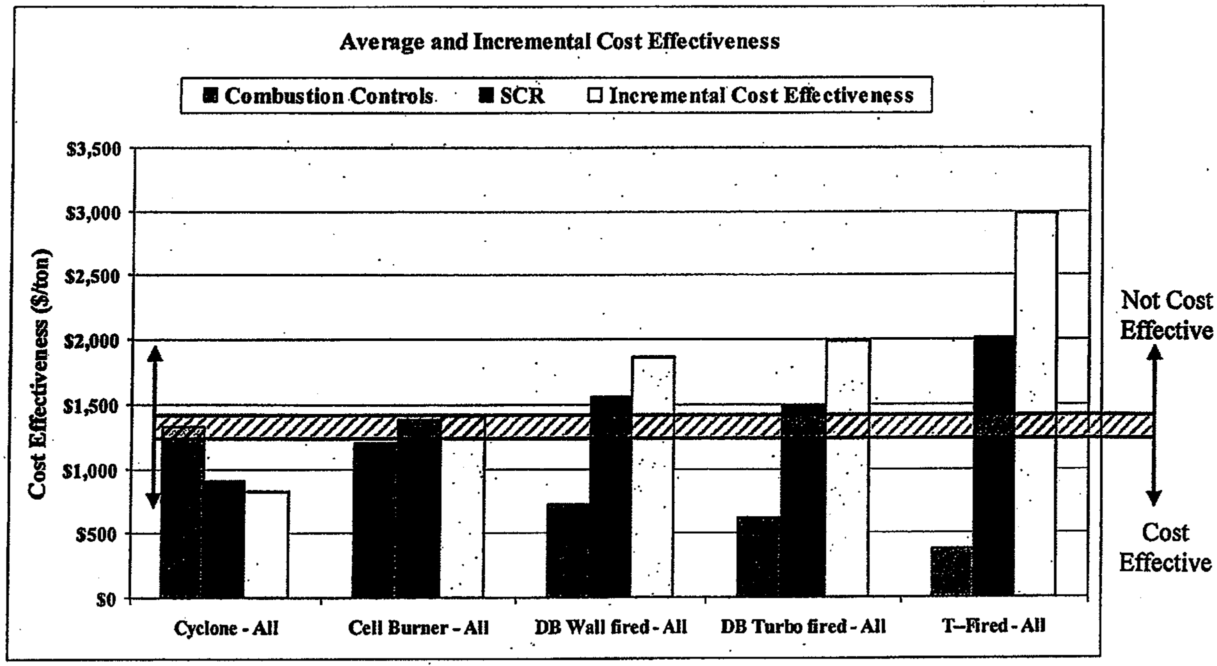


For all boiler types other than cyclones, combustion controls were determined to be a cost-effective NOx retrofit control option while post-combustion SCR was not considered to be cost-effective. Combustion controls had an overall average cost effectiveness (calculated by dividing total annual costs by total annual tons of NOx removed for all boiler categories other than cyclones) of approximately $535/ton, and ranged from $281/ton (T-Fired subbituminous units) to $1,296/ton (DW Wall-Fired lignite units). SCR had an overall average cost effectiveness of $1,749/ton, ranging from $1,016/ton (Cell Burner – subbituminous) to $3,060/ton (T-Fired lignite units). Other than Cyclone Boilers, the Cell Burner category had the highest combustion control cost-effectiveness and the lowest SCR cost-effectiveness at $1,198/ton and $1,383/ton, respectively.

Conversely, SCR, rather than combustion controls, were determined to be cost-effective on Cyclone Boilers. The average cost-effectiveness of combustion controls and SCR on Cyclone Boilers was determined to be $1,330/ton and $901/ton, respectively.

Figure 3 shows the average and incremental cost-effectiveness for combustion controls and SCR on each boiler type, and shows the approximate thresholds used by EPA to establish cost-effectiveness.

Figure 3
Average and Incremental Cost Effectiveness of NOx Retrofit Controls
Showing Cost-Effectiveness Thresholds



Based on the cost impact evaluation prepared by EPA to establish the presumptive BART limits, it can be concluded that a threshold of $1,350/ton should be used to establish the cost-effectiveness of NOx retrofit control technologies. In general, control technologies that had a cost impact of less than $1,350/ton were determined to be cost-effective (e.g., combustion controls on all boiler types other than cyclones), while control technologies that had a cost impact greater than $1,350 were determined not to be cost-effective (e.g., SCR on all boiler types other than cyclones).[7]

Again, the purpose of this letter report is to summarize EPA's determination of cost-effectiveness thresholds for retrofit emission control technologies under the Regional Haze Rule. This evaluation of EPA's cost-effectiveness threshold for retrofit emission control technologies was based on a review of EPA documents published to support the Regional Haze Rule, and should be directly applicable to cost-effectiveness evaluations included in the Leland Olds BART Determination Study.

Should you need additional information, please do not hesitate to contact me.

Very Truly Yours,

William DePriest
Sr. Vice President and
Director Environmental Services

---

[7] EPA's cost impact evaluation included a couple of notable exceptions to this general statement. For example, combustion controls on both lignite- and subbituminous-fired Cyclone Boilers had a cost-effectiveness of $1,161/ton and $1,167/ton (which is below the $1,350/ton threshold). Similarly, post-combustion SCR on subbituminous-fired Cell Burners had a cost impact of $1,016/ton (which is below the $1,350/ton threshold).

Re: Comments on Notice of Intent to Amend the State Implementation Plan for Air Pollution Control Relating to Reduction of Regional Haze

Please accept the attached document that was developed by Bob Paine, from AECOM, on behalf of the undersigned Electric Cooperatives. Mr. Paine presents valid arguments for re-visiting natural background conditions and re-setting the glide path. He recommends additional modeling to exclude uncontrollable particulate matter (PM) emissions, such as windblown dust and wildfires, as well as international SO2 and NOx emissions, which are not within the jurisdiction of the North Dakota Department of Health. The North Dakota Department of Health should also consider Mr. Paine's recommendations as part of their weight of evidence for determining reasonable progress under the Regional Haze Requirements.

Enc: "Visibility Projections at North Dakota Class 1 Areas with Consideration of Uncontrollable Emissions" dated January 6, 2010

Visibility Projections at North Dakota Class I Areas with Consideration of Uncontrollable Emissions

(Comments provided for revisions to the North Dakota State Implementation Plan for Air Pollution Control Relating to the Reduction of Regional Haze)

Robert Paine, AECOM Environment
January 6, 2010

Introduction

The purpose of this document is to comment on the use of the default natural visibility conditions defined by the United States Environmental Protection Agency (USEPA)[1] to assess progress in attaining the goals of the Regional Haze Rule (RHR), which is the subject of the North Dakota State Implementation Plan (SIP). In its December 2, 2009 draft SIP, North Dakota notes in Section 8.6.3.3 that,

> "Achieving natural conditions will require the elimination of all anthropogenic sources of emissions. Given current technology, achieving natural conditions is an impossibility. Any estimate of the number of years necessary to achieve natural visibility conditions would require assumptions about future energy sources, technology improvements for sources of emissions, and every facet of human behavior that causes visibility impairing emissions. The elimination of all SO_2 and NO_x emissions in North Dakota will not achieve the uniform rate of progress for this [2018], or any future planning period. Any estimate of the number of years to achieve natural conditions is questionable because of the influence of out-of-state sources."

It is clear that the use of USEPA default natural conditions leads to unworkable and absurd results for North Dakota's ability to determine the rate of progress toward an unattainable goal. The definition of natural conditions that can be reasonably attained for a reasonable application of USEPA's Regional Haze Rule must be revised. USEPA provides each state with ability to do this, and North Dakota should seriously consider this option.

The objective of this memorandum is to summarize recent modeling studies of natural visibility conditions and to suggest how such studies can be used in evaluating the uniform rate of progress in reducing haze to attain natural visibility levels. In addition, the distinction between natural visibility and policy relevant background visibility is discussed. Treatment of this issue by other states who are also considering what to do for their Regional Haze Rule SIPS is also discussed.

---

[1] USEPA, 2003. *Guidance for Estimating Natural Visibility Conditions under the Regional Haze Rule.* EPA-454/B03-005. http://www.epa.gov/ttn/oarpg/t1/memoranda/rh_envcurhr_gd.pdf.

Natural Haze Levels

The Regional Haze Rule establishes the goal that natural visibility conditions should be attained in Federal Class I areas by the year 2064. Additionally, the states are required to determine the uniform rate of progress (URP) of visibility improvement necessary to attain the natural visibility goal by 2064. Finally, each state must develop a SIP identifying reasonable control measures that will be adopted well before 2018 to reduce source emissions of visibility-impairing particulate matter (PM) and its precursors (SO_2 and NO_x).

Estimates of natural haze levels have been developed by the USEPA for visibility planning purposes and are described in the above-referenced USEPA 2003 document. The natural haze estimates were based on ambient data analysis of selected PM species for days with good visibility and are shown in Table 1. These estimates were derived from Trijonis (1990)[2] and use two different sets of natural concentrations for the eastern and western U.S. Tombach (2008)[3] provides a detailed review and discussion of uncertainty in the USEPA natural PM estimates. Natural visibility can be calculated using the IMPROVE equation which calculates the light scattering caused by each component of PM. Objections have been raised both in the assumed natural concentrations of PM and in the method by which the IMPROVE equation is used to calculate visibility (EPRI, 2004). In response, changes in the IMPROVE equation and in the method for calculating natural visibility were developed in 2005 and are described by Pitchford et al.[4]

The USEPA guidance also makes provision for refined estimates of site-specific natural haze that differ from the default values using either data analysis or model simulations. However, most states have continued to use the default natural haze levels for calculating the progress toward natural visibility conditions. Tombach and Brewer (2005)[5] reviewed natural sources of PM and identified several Class I areas for which evidence supports adjustments to the natural levels. Tombach (2008) also reviewed estimates of natural haze levels and proposed that, instead of using two sets of default natural PM concentrations for the eastern and western US, a large number of sensitivity zones should be developed that reflect regional variability in natural PM sources. Tombach (2008) also suggested that modeling studies are a possible approach to further revise estimates of natural PM concentrations.

Previous modeling studies have shown that the estimates of natural visibility described above for "clean" days will differ from the results of model simulations when United States anthropogenic emissions are totally eliminated (Tonnesen et al., 2006[6]; Koo et al., 2009[7]), especially when natural wild fire emissions are

included in the model simulation. Because the URP is calculated using model simulations of PM on the 20% of days with the worst visibility, wild fires and other extreme events can result in modeled levels of natural haze (even without any contribution of US anthropogenic sources) that are significantly greater than the natural levels used in the USEPA guidance for URP calculation. This could make it difficult or impossible for states to identify emissions control measures sufficient to demonstrate the URP toward attaining visibility goals because the endpoint is unachievable even if all US anthropogenic emissions are eliminated, as North Dakota has already determined even for the interim goal in 2018.

Modeling studies for natural ozone and PM have been completed at the global scale with the GEOS-CHEM model (Fiore et al., 2003[8]; Park et al., 2004[9]). Park et al. (2006)[10] estimated the contribution of both natural PM and international transport of PM in the eastern and western U.S. and compared their results to the USEPA default natural concentrations. They found significantly less difference in the natural concentrations between the east and west compared to the USEPA default values. Their modeled western concentrations were greater than the USEPA default values, while their modeled eastern concentrations were lower than the default values.

Tonnesen et al. (2006)[11] performed visibility modeling simulations for the WRAP using a "clean emissions" scenario in which all (US and international) anthropogenic emissions were removed from the model, and the GEOS-CHEM natural simulation was used to provide boundary conditions for CMAQ. This CMAQ simulation was not considered an adequate representation of natural conditions because some natural emissions data were not available. However, it did include natural fire emissions and was useful for showing the maximum visibility possible when all US and international anthropogenic emissions were totally eliminated. The model results were evaluated for annual average visibility and extinction coefficient, shown in Figure 1. The largest source of natural emissions in this model simulation was from wildfires, which were predominantly located in the Western US.

More recently, Koo et al. (2009) have completed CMAQ model simulations of natural ozone and haze levels using a more complete natural emissions inventory. The updated Koo et al. natural visibility modeling is currently the best available estimate of natural visibility for the worst 20% model days. It represents the absolute maximum visibility conditions possible in the model when all anthropogenic US and international emissions are controlled. However, those results have not yet been evaluated to identify the modeled natural concentrations for the worst 20% visibility days.

Policy Relevant Background Visibility

The use of natural haze levels is an unattainable goal for U.S. domestic planning purposes because the Regional Haze Rule does not have jurisdiction over international emissions. A more appropriate goal would be based on the background concentration resulting from a combination of natural PM and international transport of PM.

For air quality planning purposes, the USEPA has identified the policy-relevant background (PRB) ozone concentration as that which would occur in the United States in the absence of anthropogenic emissions of VOC and NO_x in continental North America (USEPA, 2007). The PRB ozone concentration represents the contribution of international transport of ozone and photochemical production from biogenic VOC and NO_x precursors within North America. The PRB is useful for ozone planning using air quality models because it defines the minimum level of ozone that can be simulated in the model when all anthropogenic emissions of VOC and NO_x are controlled 100% in North America. Similarly, PRB levels could be defined for $PM_{2.5}$ and for haze, and this would be useful for estimating the rate of progress that the states are making through the control of domestic sources of visibility impairing species.

PRB levels of haze can be evaluated in air quality model simulations by excluding all anthropogenic emissions within North America, or more appropriately, excluding all anthropogenic emissions within the US only (especially relevant for North Dakota). Such model simulations have not yet been completed; however, existing RPO data sets could be modified to perform new CMAQ simulations for use in this analysis.

The RPOs have completed modeling studies using source apportionment tools to evaluate individual sources that contribute to visibility impairment at Class I Areas. Both WRAP and CENRAP have performed CAMx simulations using the Particulate Source Apportionment Tool (PSAT) to evaluate emissions sources that contribute to sulfate and nitrate at receptor sites. Figure 2 shows the CAMx PSAT results for major contributors to sulfate for the 20% worst visibility days at the Lostwood Wilderness Area (LWA) and Theodore Roosevelt National Park (TRNP) Class I areas. The source apportionment results provide some of the same information that would be obtained from model simulations to evaluate PRB haze. For example, the contribution of boundary conditions in the CAMx PSAT results represent contributions of international transport from areas outside the model domain, although parts of in Canada and Mexico are included within the model domain and are represented explicitly in the PSAT results. Figure 2 shows that in the PSAT results, Canadian point sources of SO_2 (PT_CN) and international transport were the two largest sources of sulfate at both the LWA and TRNP Class I areas, producing approximately 1.6 ug/m^3 of sulfate of the total of 2.48 ug/m^3 at LWA, and approximately 0.93 ug/m^3 of sulfate of the total of 1.61 ug/m^3 at TRNP. For both sites, point sources of SO_2 within North Dakota were ranked below these sources as the third largest source of sulfate in the PSAT results.

While the PSAT results are useful for identifying the relative important of different source regions and emissions source categories at individual Class I Areas, there would be advantages to also performing a model simulation that included only international transport (including Canadian and Mexican emissions) and natural emissions to more accurately estimate PRB haze levels that North Dakota could then adopt as a refined natural background visibility goal for the Regional Haze Rule.

Texas and Colorado SIP Issues

There are many similarities between the Regional Haze Rule (RHR) challenges for North Dakota and Texas in that both states have significant international and natural contributions to regional haze in Class I areas in their states. The Texas Commission on Environmental Quality (TCEQ) has introduced alternative RHR glide paths to illustrate their rate of progress toward the RHR goals. Since TCEQ has already gone through the process of a RHR State Implementation Plan (SIP) development and comment period, it is instructive for the North Dakota to look at the TCEQ approach, the comments provided to TCEQ, and TCEQ's reaction to the comments.

In addition, Colorado's approach to Reasonable Further Progress prudently focuses upon source groups and particulate species for which Colorado sources contribute significantly to regional haze for the worst 20% haze days. This approach, consistent with that of Texas, concludes that some of the particulate species that contribute to regional haze are highly variable, not principally from anthropogenic sources, difficult to model, and difficult to control.

Similarities Between North Dakota and Texas

Similarities to be considered for the RHR SIP development in both North Dakota and Texas include the items listed below.

- Both states have Class I areas for which a considerable fraction of the regional haze is due to international transport
- Both states have Class I areas in their western portion, which results in the prevailing winds taking emissions from within their states away from those Class I areas.
- The distance to the nearest Class I areas associated with the prevailing winds is many hundreds of kilometers.
- The impact of the large haze precursor emitters in each state is noticeable when the wind directions advect their plumes toward the Class I areas, but this happens only a small fraction of the time.
- As a result, there is a substantial reduction in SO_2 and NO_x emissions from the BART-eligible sources in each state, but this reduction results in a relatively small impact on regional haze mitigation. Additional emission reductions that are advocated by some commenters would, therefore, have a minimal benefit on visibility improvement at substantial cost.
- In the RHR SIP development, both states have attempted to account for the effects of anthropogenic emissions that they can control in alternative analyses. These analysis result in a finding that the in-state emission reductions come closer to meeting the Uniform Rate of Progress glide path goals for 2018. However, due to the low probability of impact of these sources on the worst 20% days, the effectiveness of in-state emission controls on anthropogenic sources subject to controls is inherently limited.

Differences Between RHR SIP Approaches: North Dakota and Texas

Although both North Dakota and Texas have presented alternative analyses that attempt to present the effect of emissions that each state can control and discount the rest, the two states have used different approaches. The nature of these differences and a discussion of the approaches taken by each state are noted below.

- North Dakota appears to have not reduced the deciview value of the natural condition endpoint, but instead altered the beginning point. On the other hand, TCEQ appears to have altered the endpoint. It is my opinion that altering the endpoint to reflect haze components that are currently affecting visibility but which cannot be controlled by the Regional Haze Rule has its merits. The beginning point is set by observations, so it should not be altered.

- TCEQ decided that coarse and fine PM measured at the Class I areas were due to natural causes (especially on the worst 20% days), and adjusted the natural conditions endpoint accordingly. The Federal Land Managers (FLMs) agreed with this approach for the most part[12], but suggested that only 80% of these concentrations would be due to natural causes, and 20% would be due to anthropogenic causes. TCEQ determined from a sensitivity analysis that the difference in these two approaches was too small to warrant a re-run of their analysis, but it is important that the FLMs agreed to a state-specific modification of the natural conditions endpoint, and this substantially changed the perceived rate of progress of the SIP plan toward the altered natural conditions endpoint.

- Although the TCEQ did not address other particulate matter components in this same way, our independent analysis of the worst 20% haze days in 2002 for Class I areas in North Dakota suggest that other components, such as organic matter due to wildfires, could be substantially due to natural causes, so that this component should also be considered as at least partially natural.

- The TCEQ discussed the issue of how emissions from Mexico could interfere with progress on the RHR, but they did not appear to adjust the glide path based upon Mexican emissions. On the other hand, North Dakota did make adjustments based upon anthropogenic emissions that could be controlled, but did not take into account any specific particulate species that are generally not emitted by major anthropogenic sources of SO_2 and NO_x.

Colorado RHR Issues Consistent with Texas

Similar to Texas, Colorado[13] has determined that SO_2 and NO_x are precursors to important visibility PM species, are predominantly due to anthropogenic sources, and can be effectively controlled for stationary sources. The other four PM species that affect visibility are coarse and fine matter as well as organic and

---

[12] See Appendix 2-2 at http://www.tceq.state.tx.us/implementation/air/sip/bart/haze_appendices.html.

[13] Colorado has posted stakeholder presentations at http://www.cdphe.state.co.us/ap/RegionalHaze/RHFeb08reasonableprogress.pdf and http://www.cdphe.state.co.us/ap/RegionalHaze/stakepresentation02-27-08.pdf.

elemental carbon. Colorado has determined that sources of these constituents are mostly natural and difficult to quantify, model, and control. This is consistent with Texas in that the focus should be on the progress made in controlling emissions from stationary sources of SO_2 and NO_x. In North Dakota, the recommended BART reductions for SO_2 and NO_x sources go well beyond the fractional progress toward zero emissions by the first milestone year of 2018, which represents less than 25% of the time period of the RHR implementation.

Recommendations and Conclusions

I recommend that North Dakota consider alternative endpoints to the natural conditions glide path for progress on the worst 20% haze days in order to indicate a more rational analysis. The use of the natural conditions provided by the default EPA approach to the RHR results in an outcome that is counterintuitive and frustrating because it indicates that even with a total shutdown of in-state emissions, not even the 2018 goal is met.

North Dakota could accomplish this goal in one of two ways. It could, similar to what was done in Texas, identify particulate matter components that are inherently dominated by natural emission sources such as windblown dust and wildfires on the worst 20% haze days. For example, the FLMs have already agreed with Texas that 80% of the coarse and fine particulate matter for these days could be considered to be uncontrollable and due to natural causes. I recommend that organic matter be added to this list, for which well over 50% would likely be attributable to natural causes (wildfires) on the 20% worst haze days when this particulate matter component is dominant. However, this approach does not address the issue of uncontrollable international emissions.

Therefore, a better approach that I recommend[14] would be to combine the effects of the uncontrollable particulate matter components and the SO_2 and NO_x emissions from international sources to determine a new glide path endpoint that is achievable by controlling anthropogenic emissions within the USA only. To compute this new endpoint, I recommend that CMAQ modeling be conducted for the base case (already done) and then for a future endpoint case with no USA anthropogenic emissions, but with particular matter emissions associated with uncontrollable coarse matter, fine matter, and organic carbon, as well as for SO_2 and NO_x emissions associated with all non-USA sources set to the current baseline levels. Then, North Dakota could use a relative reduction factor (RRF) approach to determine the ratio of the haze impacts between the base case and the reasonable future case, and then apply the RRF values to the baseline haze to obtain a realistic "natural conditions" haze endpoint.

---

[14] These comments and recommendations were discussed with Gail Tonneson, who has provided helpful input and review for this document.

Table 1: Average Natural Levels of Aerosol Components from Table 2-1 of *Guidance for Estimating Natural Visibility Conditions Under the Regional Haze Rule* (EPA, 2003)

	Average Natural Concentration		Error Factor	Dry Extinction Efficiency (m^2/g)
	West ($\mu g/m^3$)	East ($\mu g/m^3$)		
Ammonium sulfate [b]	0.12	0.23	2	3
Ammonium nitrate	0.10	0.10	2	3
Organic carbon mass [c]	0.47	1.40	2	4
Elemental carbon	0.02	0.02	2-3	10
Soil	0.50	0.50	1½ - 2	1
Coarse Mass	3.0	3.0	1½ - 2	0.6

a: After Trijonis, see footnote 12

b: Values adjusted to represent chemical species in current IMPROVE light extinction algorithm; Trijonis estimates were 0.1 $\mu g/m^3$ and 0.2 $\mu g/m^3$ of ammonium bisulfate.

c: Values adjusted to represent chemical species in current IMPROVE light extinction algorithm; Trijonis estimates were 0.5 $\mu g/m^3$ and 1.5 $\mu g/m^3$ of organic compounds.

Re: Comments on Notice of Intent to Amend the State Implementation Plan for Air Pollution Control Relating to Reduction of Regional Haze

Great River Energy is a generation and transmission electric cooperative based in Maple Grove, Minnesota. Our two coal-fired power plants are located in North Dakota: Coal Creek Station, a 1,129-megawatt plant located near Underwood; and Stanton Station, a 190-megawatt plant located near Stanton. Great River Energy respectfully provides the following general comments to North Dakota's Regional Haze State Implementation Plan ("SIP").

Since 2005, Great River Energy has been working with the North Dakota Department of Health ("NDDH") to define Best Available Retrofit Technologies ("BART") for three of our coal-fired units in North Dakota. Both Coal Creek Units 1 and 2, as well as Stanton Station Unit 1, are BART affected sources due to their dates of construction and their modeled contributions to visibility impairment in North Dakota Class 1 areas, Lostwood Wilderness Area and Theodore Roosevelt National Park's North, South and Elkhorn Units.

Great River Energy originally submitted detailed BART analyses for our affected units, Stanton and Coal Creek stations, in June and August, respectively, of 2006. Each BART submittal was amended several times in response to Environmental Protection Agency ("EPA"), Federal Land Manager and NDDH comments. Stanton's final BART submittal was provided in January 2008 and Coal Creek's in December 2007. These documents were the foundations for the NDDH BART determinations, and draft Title V permits-to-construct, which were issued in May of 2008, and act as reference materials in the NDDH Regional Haze Rule SIP.

NDDH technical modeling appropriately utilizes the most up-to-date modeling science as grounded by actual monitored data to ensure relative accuracy.

Great River Energy supports using the best and most current science as part of regulatory decision making. Specifically, Great River Energy strongly believes that "models" must be calibrated to actual monitored data, as much as technically feasible. It is clear that models must be "tuned" to meet local conditions in order to provide more accurate results. Otherwise, uncalibrated modeled results will not provide the necessary foundation for regulatory decision making. Modeling science continues to develop as new chemistry and better meteorology are incorporated.

With respect to regional haze modeling, NDDH spent significant technical resources and time "calibrating" EPA's default model, by nesting CALPUFF within CMAQ for more refined treatment of plume dispersion than would have otherwise been accomplished with the CMAQ model. The hybrid CMAQ-CALPUFF model was "tuned" to local monitored results and then used to project emissions for the glide path. It was clear that the NDDH's technical efforts provided a more accurate model in most situations. For future modeling, Great River Energy encourages NDDH to continue to use the most up-to-date modeling science, and to continue to calibrate these models with actual monitored data to ensure their relative accuracy.

The glide path is a "goal" and not an absolute, as defined by rule. "Natural," or non-manmade, and international sources are both significant and outside of NDDH control.

NDDH must preserve its ability to adjust the glide path for non-manmade and international emissions, which are completely outside of its control. As part of the weight of evidence, NDDH has modeled a scenario that eliminates all North Dakota emission sources that were used in the baseline. Even "zero"ing these emissions, NDDH demonstrates that the state cannot hit the first reasonable progress goal in 2018. In short, the international and non-manmade emissions are more significant in achieving "natural background" conditions than ND sources contained in the modeling database. By adjusting the glide path to exclude non-manmade and international emissions, as part of its weight of evidence, NDDH can more accurately demonstrate reasonable progress towards natural background conditions in 2064 through reductions over which it has control.

The BART rule treats smaller, non-presumptive sources (less than 750 MW) differently. EPA determined that these smaller sources should not be held to presumptive limits, unless the state exercises its discretion in order to meet reasonable progress goals.

It is important to note that significant technical and financial resources were spent to provide the complete BART evaluations and other supporting documentation. National emission control experts, including but not limited to Alstom, URS, and the Washington Group, were hired to provide engineering estimates based on their knowledge of recently installed controls, material costs, and site specific limitations. Their site specific recommendations should be considered more accurate than comparable information that could have been derived from older cost manuals, which are then adjusted for inflation, as suggested by the Federal Land Managers.

EPA clearly established presumptive BART emission rates for sources greater than 750 MW. These emission rates were deemed cost effective based on EPA's cost per ton estimates. NDDH BART determinations represent higher cost effective determinations than the BART rule. As an example, NDDH appears to use a somewhat arbitrary and largely unsubstantiated $3600/ton cost effectiveness threshold, as compared to ~$1000/ton in the BART rule. Great River Energy provided an analysis of cost effective controls as supported by the BART rule in our Cost Effectiveness Memo, dated July 3, 2007, which was included as an appendix in Coal Creek and Stanton stations' final BART determinations.

Given the inaccuracy of the model(s), as discussed, and the costly control of emissions, it is imperative that reasonable, cost effective determinations be consistently applied, not only in North Dakota but in the region, to ensure competitive energy production. The Regional Haze and BART rules have distinct requirements to make reasonable progress towards a goal of natural background conditions, in a cost effective manner, as deemed appropriate by the North Dakota Department of Health.

Although more than the rule requires, Great River Energy generally supports NDDH BART determinations as being within their statutory discretion to meet glide path goals.

Sincerely,

Mary Jo Roth

ATTORNEY GENERAL'S OPINION
Statement of Authority

State Plan for Implementing 40 C.F.R. § 51.308, Regional Haze Program Requirements

At the request of the North Dakota Department of Health (Department), I have reviewed the relevant elements of the Regional Haze State Implementation Plan (SIP) submitted by the Department to the Environmental Protection Agency (EPA) for approval in accordance with Section 110 of the Clean Air Act (CAA). As discussed in more detail below, it is my opinion that North Dakota law currently provides adequate authority for the Department to adopt and implement the Regional Haze SIP, including the Permits to Construct issued as part of the SIP. This opinion includes a review of the statutes, rules, and other legal authority for the SIP. Attached to this opinion are the relevant sections of North Dakota law.

I. Authority to Adopt the Plan

North Dakota's legislature has designated the Department as "the agency to administer and coordinate a statewide program of air pollution control." N.D.C.C. § 23-25-02(1). The Department has the authority to cooperate with EPA and to "develop and implement" federal air pollution prevention and control programs. N.D.C.C. § 23-25-03(4), (12). In order to implement and enforce a federal program, the Department may adopt rules, including rules setting ambient standard and emission limitations. N.D.C.C. § 23-25-03(8), (12). A person must obtain a permit from the Department to "construct, install, modify, use, or operate an air contaminant source" and the Department may impose requirements on the issuance of such permits. N.D.C.C. § 23-25-04.1(1)-(3); see N.D. Admin. ch. 33-15-14. The Department properly adopted rules implementing the Regional Haze Requirements, which became effective January 1, 2007. See N.D. Admin. ch. 33-15-25. Accordingly, the Department has the authority to adopt the Regional Haze SIP.

II. Authority to Implement the Plan

The Department also has the legal authority to carry out the Regional Haze SIP, as required by 40 C.F.R. § 51.230. Specifically, the Department has the authority to:

- Adopt emission standards and limitations and any other measures necessary for attainment and maintenance of national standards: N.D.C.C. § 23-25-03(8), (12).
- Enforce applicable laws, regulations, and standards, and seek injunctive relief: N.D.C.C. §§ 23-25-03(5) and 23-25-10.
- Abate pollutant emissions on an emergency basis to prevent substantial endangerment to the health of persons: N.D.C.C. §§ 23-25-03(5), 23-25-08, and 23-25-10(5).
- Prevent construction, modification, or operation of a facility, building, structure, or installation, or combination thereof, which directly or indirectly results or may result in emissions of any air pollutant at any location which will prevent the attainment or maintenance of a national standard: N.D.C.C. §§ 23-25-03(5)-(6), 23-25-04.1(1)-(2), and 23-25-10(5); N.D. Admin. §§ 33-15-14-02, 33-15-14-06, and 33-15-25-02.
- Obtain information necessary to determine whether air pollution sources are in compliance with applicable laws, regulations, and standards, including authority to require recordkeeping and to make inspections and conduct tests of air pollution sources: N.D.C.C. §§ 23-25-03(10), 23-25-04.1(2), and 23-25-05(1)-(2); N.D.

Admin. §§ 33-15-14-02(9), 33-15-14-06(4)-(5), 33-15-25-04.

- Require owners or operators of stationary sources to install, maintain, and use emission monitoring devices and to make periodic reports to the State on the nature and amounts of emissions from such stationary sources; also authority for the State to make such data available to the public as reported and as correlated with any applicable emission standards or limitations: N.D.C.C. §§ 23-25-03(10) and 23-25-04.1(2); N.D. Admin. §§ 33-15-14-02(9), 33-15-14-06(5), and 33-15-25-04.

III. The Department Complied with State Law Procedural Requirements in Issuing the Permits to Construct

In addition to the above, I have reviewed the Department's Public Hearing Notice and other relevant information. Based on this review, it is my opinion that the Permits to Construct were issued in compliance with state procedural requirements. See N.D.C.C. § 23-01-23; N.D. Admin. § 33-15-14-02(6).

Dated this 26th day of February, 2010.

State of North Dakota

Wayne Stenehjem
ATTORNEY GENERAL

e:\olson\health\air pollution\rhsip.agop.2-25-10.docx

Relevant Sections of the North Dakota Century Code

23-01-23. Permit or investigatory hearings - Exemption from chapters 28-32 and 54-57. A permit hearing conducted for purposes of receiving public comment or an investigatory hearing conducted under chapters 23-20.1, 23-20.3, 23-25, 23-29, 61-28, and 61-28.1 is not an adjudicative proceeding under chapter 28-32 and is not subject to the requirements of chapter 54-57.

23-25-02. State air pollution control agency - Advisory council.

1. The state department of health, hereinafter referred to as the department, is hereby designated as the agency to administer and coordinate a statewide program of air pollution control consistent with the provisions of this chapter.

23-25-03. Power and duties of the department. The department shall:

1. Encourage the voluntary cooperation of persons or affected groups to achieve the purposes of this chapter.
2. Determine by scientifically oriented field studies and sampling the degree of air pollution in the state and the several parts thereof.
3. Encourage and conduct studies, investigations, and research relating to air pollution and its causes, effects, prevention, abatement, and control.
4. Advise, consult, and cooperate with other public agencies and with affected groups and industries.
5. Issue such orders as may be necessary to effectuate the purposes of this chapter and enforce the same by all appropriate administrative and judicial procedures.
6. Provide rules and regulations relating to the construction of any new direct or indirect air contaminant source or modification of any existing direct or indirect air contaminant source which the department determines will prevent the attainment or maintenance of any ambient air quality standard, and require that prior to commencing construction or modification of any such source, the owner or operator thereof shall submit such information as may be necessary to permit the department to make such determination.
7. Establish ambient air quality standards for the state which may vary according to appropriate areas.
8. Formulate and promulgate emission control requirements for the prevention, abatement, and control of air pollution in this state including achievement of ambient air quality standards.

9. Hold hearings relating to any aspect or matter in the administration of this chapter, and in connection therewith, compel the attendance of witnesses and the production of evidence.

10. Require the owner or operator of a regulated air contaminant source to establish and maintain such records; make such reports; install, use, and maintain such monitoring equipment or methods; sample such emissions in accordance with such methods, at such locations, intervals, and procedures; and provide such other information as may be required.

11. Provide by rules and regulations a procedure for the handling of applications for the granting of a variance to any person who owns or is in control of any plant, establishment, process, or equipment. The granting of a variance is not a right of the applicant but must be in the discretion of the department.

12. Provide by rules any procedures necessary and appropriate to develop, implement, and enforce any air pollution prevention and control program established by the Federal Clean Air Act, as amended, and the authorities and responsibilities of which are delegatable to the state by the United States environmental protection agency. Such rules may include any and all enforceable ambient standards, emission limitations, and other control measures, means, techniques, or economic incentives such as fees, marketable permits, and auctions of emissions rights as provided by the Act. The department shall develop and implement such federal programs if the department determines there is a benefit to the state.

13. Provide by rules a program for implementing lead-based paint remediation training, certification, and performance requirements in accordance with title 40, Code of Federal Regulations, part 745, sections 220, 223, 225, 226, 227, and 233.

After consultation with the advisory council, the department is empowered to adopt, amend, and repeal rules and regulations implementing and consistent with this chapter.

23-25-04.1. Permits or registration.

1. No person shall construct, install, modify, use, or operate an air contaminant source designated by regulation, capable of causing or contributing to air pollution, either directly or indirectly, without a permit from the department or in violation of any conditions imposed by such permit.

2. The department shall provide for the issuance, suspension, revocation, and renewal of any permits which it may require pursuant to this section.

3. The department may require that applications for such permits shall be accompanied by plans, specifications, and such other information as it deems necessary.

4. Possession of an approved permit or registration certificate does not relieve any person of the responsibility to comply with applicable emission limitations or with any other provision of law or regulations adopted pursuant thereto and does not relieve any person from the requirement that that person possess a valid contractor's license issued under chapter 43-07.

5. The department by rule or regulation may provide for registration and registration renewal of certain air contaminant sources in lieu of the permit required pursuant to this section.

6. The department may exempt by rule and regulation certain air contaminant sources from the permit or registration requirements set forth in this section when the department makes a finding that the exemption of such sources of air contaminants will not be contrary to section 23-25-01.1.

23-25-05. Right of onsite inspection.

1. Any duly authorized officer, employee, or agent of the department may enter and inspect any property, premise, or place on or at which an air contaminant source is located or is being constructed, installed, or established at any reasonable time for the purpose of ascertaining the state of compliance with this chapter and rules and regulations enforced pursuant thereto. If requested, the owner or operator of the premises shall receive a report setting forth all facts found which relate to compliance status.

2. The department may conduct tests and take samples of air contaminants, fuel, process material, and other materials which affect or may affect emission of air contaminants from any source, and shall have the power to have access to and copy any records required by department rules or regulations to be maintained, and to inspect monitoring equipment located on the premises. Upon request of the department, the person responsible for the source to be tested shall provide necessary holes in stacks or ducts and such other safe and proper sampling and testing facilities exclusive of instruments and sensing devices as may be necessary for proper determination of the emission of air contaminants. If an authorized representative of the department, during the course of an inspection, obtains a sample of air contaminant, fuel, process material, or other material, that representative shall issue a receipt for the sample obtained to the owner or operator of, or person responsible for, the source tested.

3. For the purpose of ascertaining the state of compliance with this chapter and any applicable rules, any duly authorized officer, employee, or agent of the

department may enter and inspect, at any reasonable time, any property, premises, or place on or at which a lead-based paint remediation activity is ongoing. If requested, the department shall provide to the owner or operator of the premises a report that sets forth all facts found which relate to compliance status.

23-25-08. Administrative procedure and judicial review. Any proceeding under this chapter for:

1. The issuance or modification of rules and regulations including emergency orders relating to control of air pollution; or

2. Determining compliance with rules and regulations of the department,

must be conducted in accordance with the provisions of chapter 28-32, and appeals may be taken as therein provided. When an emergency exists requiring immediate action to protect the public health and safety, the department may, without notice or hearing, issue an order reciting the existence of such emergency and requiring that such action be taken as is necessary to meet this emergency. Notwithstanding any provision of this chapter, such order must be effective immediately, but on application to the department an interested person must be afforded a hearing before the state health council within ten days. On the basis of such hearing, the emergency order must be continued, modified, or revoked within thirty days after such hearing. Except as provided for in this section, notice of any hearing held under this chapter must be issued at least thirty days prior to the date specified for the hearing.

23-25-10. Enforcement - Penalties - Injunctions.

1. Any person who willfully violates this chapter, or any permit condition, rule, order, limitation, or other applicable requirement implementing this chapter, is subject to a fine of not more than ten thousand dollars per day per violation, or by imprisonment for not more than one year, or both. If the conviction is for a violation committed after a first conviction of such person under this subsection, punishment must be by a fine of not more than twenty thousand dollars per day per violation, or by imprisonment for not more than two years, or both.

2. Any person who violates this chapter, or any permit condition, rule, order, limitation, or other applicable requirement implementing this chapter, with criminal negligence as defined by section 12.1-02-02, is subject to a fine of not more than ten thousand dollars per day per violation, or by imprisonment for not more than six months, or both.

3. Any person who knowingly makes any false statement, representation, or certification in any application, record, report, plan, or other document filed or required to be maintained under this chapter or any permit condition, rule,

order, limitation, or other applicable requirement implementing this chapter, or who falsifies, tampers with, or knowingly renders inaccurate any monitoring device or method required to be maintained under this chapter or any permit condition, rule, order, limitation, or other applicable requirement implementing this chapter, upon conviction, is subject to a fine of not more than ten thousand dollars per day per violation, or by imprisonment for not more than six months, or both.

4. Any person who violates this chapter, or any permit condition, rule, order, limitation, or other applicable requirement implementing this chapter, is subject to a civil penalty not to exceed ten thousand dollars per day per violation.

5. Without prior revocation of any pertinent permits, the department, in accordance with the laws of this state governing injunction or other process, may maintain an action in the name of the state against any person to enjoin any threatened or continuing violation of any provision of this chapter or any permit condition, rule, order, limitation, or other applicable requirement implementing this chapter.

CHAPTER 33-15-14
DESIGNATED AIR CONTAMINANT SOURCES, PERMIT TO CONSTRUCT, MINOR SOURCE PERMIT TO OPERATE, TITLE V PERMIT TO OPERATE

Section

33-15-14-01 Designated Air Contaminant Sources
33-15-14-01.1 Definitions
33-15-14-02 Permit to Construct
33-15-14-03 Minor Source Permit to Operate
33-15-14-04 Permit Fees [Repealed]
33-15-14-05 Common Provisions Applicable to Both Permit to Construct and Permit to Operate [Repealed]
33-15-14-06 Title V Permit to Operate
33-15-14-07 Source Exclusions From Title V Permit to Operate Requirements

33-15-14-01. Designated air contaminant sources. Pursuant to subsection 1 of North Dakota Century Code section 23-25-04, stationary sources within the following source categories are designated as air contaminant sources capable of causing or contributing to air pollution, either directly or indirectly.

1. The following chemical process facilities:

   a. Adipic acid.

   b. Ammonia.

   c. Ammonium nitrate.

   d. Carbon black.

   e. Charcoal.

   f. Chlorine.

   g. Chlor-alkali manufacturing.

   h. Detergent and soap.

   i. Explosives (trinitrotoluene and nitrocellulose).

   j. Hydrochloric acid.

   k. Hydrofluoric acid.

   l. Nitric acid.

   m. Paint and varnish manufacturing.

n. Phosphoric acid.

o. Phthalic anhydride.

p. Plastics manufacturing.

q. Printing ink manufacturing.

r. Sodium carbonate.

s. Sulfur production and recovery.

t. Sulfuric acid.

u. Synthetic fibers.

v. Synthetic rubber.

w. Terephthalic acid.

x. Alcohol.

y. Cresylic acids.

z. Phenol.

aa. Polymer manufacturing and coating operations.

2. The following food and agricultural facilities:

   a. Agricultural drying and dehydrating operations.

   b. Ammonium nitrate.

   c. Cheese whey drying and processing.

   d. Coffee roasting.

   e. Cotton ginning.

   f. Feed, grain, and seed handling and processing.

   g. Fermentation processes.

   h. Fertilizers.

    i. Fishmeal processing.
    j. Meat smokehouses.
    k. Orchard heaters.
    l. Potato processing.
    m. Rendering plants.
    n. Starch manufacturing.
    o. Sugarbeet processing.

3. The following metallurgical facilities:
    a. Primary metals facilities:
        (1) Aluminum ore reduction.
        (2) Copper smelters.
        (3) Ferroalloy production.
        (4) Iron and steel mills.
        (5) Lead smelters.
        (6) Metallurgical coke manufacturing.
        (7) Zinc.
    b. Secondary metals facilities:
        (1) Aluminum operations.
        (2) Brass and bronze smelting.
        (3) Ferroalloys.
        (4) Ferrous foundries.
        (5) Gray iron foundries.
        (6) Lead smelting.
        (7) Magnesium smelting.

        (8) Nonferrous foundries.

        (9) Steel foundries.

        (10) Zinc processes.

    c. Electrolytic plating operations.

4. The following mineral products facilities:

    a. Asphalt roofing.

    b. Asphaltic concrete plants.

    c. Bricks and related clay refractories.

    d. Calcium carbide.

    e. Ceramic and clay processes.

    f. Clay and fly ash sintering.

    g. Coal cleaning.

    h. Coal drying.

    i. Coal mining.

    j. Coal handling and processing.

    k. Concrete batching.

    l. Fiberglass manufacturing.

    m. Frit manufacturing.

    n. Glass manufacturing.

    o. Gypsum manufacturing.

    p. Leonardite mining, drying, and processing.

    q. Lime manufacturing.

    r. Mineral wool manufacturing.

    s. Paperboard manufacturing.

   - t. Perlite manufacturing.
   - u. Phosphate rock preparation.
   - v. Portland cement manufacturing, bulk handling, and storage.
   - w. Rock, stone, gravel, and sand quarrying and processing.
   - x. Uranium mining, milling, and enrichment.
   - y. Calciners and dryers.

5. The following energy and fuel facilities:
   - a. Coal gasification.
   - b. Coal liquefaction.
   - c. Crude oil and natural gas production.
   - d. Fossil fuel steam electric plants.
   - e. Fuel conversion plants.
   - f. Natural gas processing.
   - g. Petroleum refining and petrochemical operations.
   - h. Petroleum storage (storage tanks and bulk terminals).
6. The following wood processing facilities:
   - a. Plywood veneer and layout operations.
   - b. Pulpboard manufacturing.
   - c. Wood pulping.
   - d. Sawmills.
   - e. Wood products manufacturing.
7. The following waste management units or facilities:
   - a. Afterburners.
   - b. Automobile body incinerators.

  c. Conical burners.
  d. Flares.
  e. Gaseous and liquid organic compounds incinerators.
  f. Industrial waste incinerators.
  g. Open burning.
  h. Open pit incinerators.
  i. Infectious waste incinerators.
  j. Refuse incinerators.
  k. Salvage incinerators.
  l. Sewage sludge incinerators.
  m. Wood waste incinerators
  n. Municipal waste combustors.

8. The following miscellaneous facilities:
  a. Drycleaning and laundry operations.
  b. Fuel burning equipment.
  c. Internal combustion engines.
  d. Surface coating operations.
  e. Wastewater treatment plants.
  f. Water cooling towers and water cooling ponds.
  g. Stationary gas turbines.
  h. Lead acid battery manufacturing.
  i. Hydrocarbon contaminated soil remediation projects.

9. Any category of sources to which a federal standard of performance applies [40 CFR 60].

10. Any source which emits a contaminant subject to a national emission standard for hazardous air pollutants [40 CFR 61].

11. Any source which is subject to review under federal prevention of significant deterioration of air quality regulations [40 CFR 51.166].

12. Any source which is determined by the department to have an emission which affects state ambient air quality standards or the other provisions of chapter 33-15-02.

13. Any source subject to title V permitting requirements in section 33-15-14-06.

14. Any major source to which a national emission standard for hazardous air pollutants for source categories [40 CFR 63] would apply.

15. Other sources subject to a standard or requirement under the Federal Clean Air Act as amended.

History: Amended effective October 1, 1987; March 1, 1994; August 1, 1995.
General Authority: NDCC 23-25-03, 23-25-04, 23-25-04.1
Law Implemented: NDCC 23-25-04, 23-25-04.1

33-15-14-01.1. Definitions. For the purposes of this chapter:

1. "Complete" means, in reference to an application for a permit, that the application contains all the information necessary for processing the application. Designating an application complete for purposes of permit processing does not preclude the department from requesting or accepting any additional information.

2. "Construction, installation, or establishment" means:

   a. For sources subject to a standard or requirement under chapters 33-15-13, 33-15-15 (excluding increment consumption by nonmajor sources), and 33-15-22, it shall have the meaning given for construction in each of the respective chapters.

   b. For all other sources it means the placement or erection, including fabrication, demolition, or modification, of an air contaminant emissions unit and any equipment, process, or structure that will be used to reduce, physically or chemically change, or transmit to the atmosphere any air contaminant. This does not include the building that houses the source, site work, foundations, or other equipment which does not affect the amount, ambient concentration, or type of air contaminants that are emitted. With respect to a physical change or a change in the method of operation it means those onsite activities which will affect an existing emissions unit or establishment of a new unit that emits to the atmosphere.

3. "Emissions unit" has the meaning given to it in section 33-15-14-06.

4. "Minor source" means any designated air contaminant source under section 33-15-14-01 which is not required to obtain a title V permit to operate under section 33-15-14-06.

5. "Potential to emit" has the meaning given to it in section 33-15-14-06.

6. "Stationary source" has the meaning given to it in section 33-15-14-06.

History: Effective March 1, 1994; amended effective January 1, 1996.
General Authority: NDCC 23-25-03
Law Implemented: NDCC 23-25-03

33-15-14-02. Permit to construct.

1. **Permit to construct required.** No construction, installation, or establishment of a new stationary source within a source category designated in section 33-15-14-01 may be commenced unless the owner or operator thereof shall file an application for, and receive, a permit to construct in accordance with this chapter. This requirement shall also apply to any source for which a federal standard of performance has been promulgated prior to such filing of an application for a permit to construct. A list of sources for which a federal standard has been promulgated, and the standards which apply to such sources, must be available at the department's offices.

   The initiation of activities that are exempt from the definition of construction, installation, or establishment in section 33-15-14-01.1, prior to obtaining a permit to construct, are at the owner's or operator's own risk. These activities have no impact on the department's decision to issue a permit to construct. The initiation or completion of such activities conveys no rights to a permit to construct under this section.

2. **Application for permit to construct.**

   a. Application for a permit to construct a new installation or source must be made by the owner or operator thereof on forms furnished by the department.

   b. A separate application is required for each new installation or source subject to this chapter.

   c. Each application must be signed by the applicant, which signature shall constitute an agreement that the applicant will assume responsibility for the construction or operation of the new installation or source in accordance with this article and will notify the department, in writing, of the startup of operation of such source.

3. **Alterations to source.**

   a. The addition to or enlargement of or replacement of or alteration in any stationary source, already existing, which is undertaken pursuant to an approved compliance schedule for the reduction of emissions therefrom, shall be exempt from the requirements of this section.

   b. Any physical change in, or change in the method of operation of, a stationary source already existing which increases or may increase the emission rate or increase the ambient concentration by an amount greater than that specified in subdivision a of subsection 5 of any pollutant for which an ambient air quality standard has been promulgated under this article or which results in the emission of any such pollutant not previously emitted must be considered to be construction, installation, or establishment of a new source, except that:

      (1) Routine maintenance, repair, and replacement may not be considered a physical change.

      (2) The following may not be considered a change in the method of operation:

         (a) An increase in the production rate, if such increase does not exceed the operating design capacity of the source and it is not limited by a permit condition.

         (b) An increase in the hours of operation if it is not limited by a permit condition.

         (c) Changes from one operating scenario to another provided the alternative operating scenarios are identified and approved in a permit to operate.

         (d) Trading of emissions within a facility provided:

            [1] These trades have been identified and approved in a permit to operate; and

            [2] The total facility emissions do not exceed the facility emissions cap established in the permit to operate.

(e) Trading and utilizing acid rain allowances provided compliance is maintained with all other applicable requirements.

c. Any owner or operator of a source who requests an increase in the allowable sulfur dioxide emission rate for the source pursuant to section 33-15-02-07 shall demonstrate through a dispersion modeling analysis that the revised allowable emissions will not cause or contribute to a violation of the national ambient air quality standards for sulfur oxides (sulfur dioxide) or the prevention of significant deterioration increments for sulfur dioxide. The owner or operator shall also demonstrate that the revised allowable emission rate will not violate any other requirement of this article or the Federal Clean Air Act. Requests for emission limit changes shall be subject to review by the public and the environmental protection agency in accordance with subsection 6.

4. **Submission of plans - Deficiencies in application.** As part of an application for a permit to construct, the department may require the submission of plans, specifications, siting information, emission information, descriptions and drawings showing the design of the installation or source, the manner in which it will be operated and controlled, the emissions expected from it, and the effects on ambient air quality. Any additional information, plans, specifications, evidence, or documentation that the department may require must be furnished upon request. Within twenty days of the receipt of the application, the department shall advise the owner or operator of the proposed source of any deficiencies in the application. In the event of a deficiency, the date of receipt of the application is the date upon which all requested information is received.

a. Determination of the effects on ambient air quality as may be required under this section must be based on the applicable requirements specified in the "Guideline on Air Quality Models (Revised)" (United States environmental protection agency, office of air quality planning and standards, Research Triangle Park, North Carolina 27711) as supplemented by the "North Dakota Guideline for Air Quality Modeling Analyses" (North Dakota state department of health, division of air quality). These documents are incorporated by reference.

b. When an air quality impact model specified in the documents incorporated by reference in subdivision a is inappropriate, the model may be modified or another model substituted provided:

(1) Any modified or nonguideline model must be subject to notice and opportunity for public comment under subsection 6.

(2) The applicant must provide to the department adequate information to evaluate the applicability of the modified or nonguideline model. Such information must include, but is not limited to, methods like those outlined in the "Interim Procedures for Evaluating Air Quality Models (Revised)" (United States environmental protection agency, office of air quality planning and standards, Research Triangle Park, North Carolina 27709).

(3) Written approval from the department must be obtained for any modification or substitution.

(4) Written approval from the United States environmental protection agency must be obtained for any modification or substitution prior to the granting of a permit under this chapter.

5. **Review of application - Standard for granting permits to construct.** The department shall review any plans, specifications, and other information submitted in application for a permit to construct and from such review shall, within ninety days of the receipt of the completed application, make the following preliminary determinations:

a. Whether the proposed project will be in accord with this article, including whether the operation of any new stationary source at the proposed location will cause or contribute to a violation of any applicable ambient air quality standard. A new stationary source will be considered to cause or contribute to a violation of an ambient air quality standard when such source would, at a minimum, exceed the following significance levels at any locality that does not or would not meet the applicable ambient standard:

Contaminant		Averaging Time (hours)			
	Annual ($\mu g/m^3$)	24 ($\mu g/m^3$)	8 ($\mu g/m^3$)	3 ($\mu g/m^3$)	1 ($\mu g/m^3$)
SO_2	1.0	5		25	25
PM_{10}	1.0	5			
NO_2	1.0				25
CO			500		2000

b. Whether the proposed project will provide all necessary and reasonable methods of emission control. Whenever a standard of performance is applicable to the source, compliance with this criterion will require provision for emission control which will, at least, satisfy such standards.

6. **Public participation - Final action on application.**

a. The following source categories are subject to the public participation procedures under this subsection:

(1) Those affected facilities designated under chapter 33-15-13.

(2) New sources that will be required to obtain a permit to operate under section 33-15-14-06.

(3) Modifications to an existing facility which will increase the potential to emit from the facility by the following amounts:

(a) One hundred tons [90.72 metric tons] per year or more of particulate matter, sulfur dioxide, nitrogen oxides, hydrogen sulfide, carbon monoxide, or volatile organic compounds;

(b) Ten tons [9.07 metric tons] per year or more of any contaminant listed under section 112(b) of the Federal Clean Air Act; or

(c) Twenty-five tons [22.68 metric tons] per year or more of any combination of contaminants listed under section 112(b) of the Federal Clean Air Act.

(4) Sources which the department has determined to have a major impact on air quality.

(5) Those for which a request for a public comment period has been received from the public.

(6) Sources for which a significant degree of public interest exists regarding air quality issues.

(7) Those sources which request a federally enforceable permit which limits their potential to emit.

b. With respect to the permit to construct application, the department shall:

(1) Within ninety days of receipt of a complete application, make a preliminary determination concerning issuance of a permit to construct.

(2) Within ninety days of the receipt of the complete application, make available in at least one location in the county or counties in which the proposed project is to be located, a copy of its preliminary determinations and copies of or

a summary of the information considered in making such preliminary determinations.

(3) Publish notice to the public by prominent advertisement, within ninety days of the receipt of the complete application, in the region affected, of the opportunity for written comment on the preliminary determinations. The public notice must include the proposed location of the source.

(4) Within ninety days of the receipt of the complete application, deliver a copy of the notice to the applicant and to officials and agencies having cognizance over the locations where the source will be situated as follows: the chief executive of the city and county; any comprehensive regional land use planning agency; and any state, federal land manager, or Indian governing body whose lands will be significantly affected by the source's emissions.

(5) Within ninety days of receipt of a complete application, provide a copy of the proposed permit and all information considered in the development of the permit and the public notice to the regional administrator of the United States environmental protection agency.

(6) Allow thirty days for public comment.

(7) Consider all public comments properly received, in making the final decision on the application.

(8) Allow the applicant to submit written responses to public comments received by the department. The applicant's responses must be submitted to the department within twenty days of the close of the public comment period.

(9) Take final action on the application within thirty days of the applicant's response to the public comments.

(10) Provide a copy of the final permit, if issued, to the applicant, the regional administrator of the United States environmental protection agency, and anyone who requests a copy.

c. For those sources subject to the requirements of chapter 33-15-15, the public participation procedures under section 33-15-15-01.2 shall be followed.

7. **Denial of permit to construct.** If, after review of all information received, including public comment with respect to any proposed project, the department makes the determination of any one of subdivision a or b of subsection 5 in the negative, it shall deny the

permit and notify the applicant, in writing, of the denial to issue a permit to construct.

If a permit to construct is denied, the construction, installation, or establishment of the new stationary source shall be unlawful. No permit to construct or modify may be granted if such construction, or modification, or installation, will result in a violation of this article.

8. **Issuance of permit to construct.** If, after review of all information received, including public comment with respect to any proposed project, the department makes the determination of subdivision a or b of subsection 5 in the affirmative, the department shall issue a permit to construct. The permit may provide for conditions of operation as provided in subsection 9.

9. **Permit to construct - Conditions.** The department may impose any reasonable conditions upon a permit to construct, including conditions concerning:

   a. Sampling, testing, and monitoring of the facilities or the ambient air or both.

   b. Trial operation and performance testing.

   c. Prevention and abatement of nuisance conditions caused by operation of the facility.

   d. Recordkeeping and reporting.

   e. Compliance with applicable rules and regulations in accordance with a compliance schedule.

   f. Limitation on hours of operation, production rate, processing rate, or fuel usage when necessary to assure compliance with this article.

   The violation of any conditions so imposed may result in revocation or suspension of the permit or other appropriate enforcement action.

10. **Scope.**

    a. The issuance of a permit to construct for any source does not affect the responsibility of an owner or operator to comply with applicable portions of a control strategy affecting the source.

    b. A permit to construct shall become invalid if construction is not commenced within eighteen months after receipt of such permit, if construction is discontinued for a period of eighteen months or more; or if construction is not completed within a reasonable time. The department may extend the eighteen-month period upon a satisfactory showing that an extension is justified. This provision does not apply to the time period between construction of the approved phases of a phased construction project; each phase must commence construction within eighteen months of the projected and approved commencement date. In cases of major construction projects involving long lead times and substantial financial commitments, the department may provide by a condition to the permit a time period greater than eighteen months when such time extension is supported by sufficient documentation by the applicant.

11. **Transfer of permit to construct.** To ensure the responsible owners or operators, or both, are identified, the holder of a permit to construct may not transfer such permit without prior approval of the department.

12. **[Reserved]**

13. **Exemptions.** A permit to construct is not required for the following stationary sources provided there is no federal requirement for a permit or approval for construction or operation and there is no applicable new source performance standard, or national emission standard for hazardous air pollutants.

    a. Maintenance, structural changes, or minor repair of process equipment, fuel burning equipment, control equipment, or incinerators which do not change capacity of such process equipment, fuel burning equipment, control equipment, or incinerators and which do not involve any change in the quality, nature, or quantity of emissions therefrom.

    b. Fossil fuel burning equipment, other than smokehouse generators, which meet all of the following criteria:

        (1) The heat input per unit does not exceed ten million British thermal units per hour.

        (2) The total aggregate heat input from all equipment does not exceed ten million British thermal units per hour.

        (3) The actual emissions, as defined in chapter 33-15-15, from all equipment do not exceed twenty-five tons [22.67 metric tons] per year of any air contaminant and the potential to emit any air contaminant for which an ambient air quality standard has been promulgated in chapter 33-15-02 is less than one hundred tons [90.68 metric tons] per year.

    c. (1) Any single internal combustion engine with less than five hundred brake horsepower, or multiple engines with a combined brake horsepower rating less than five hundred brake horsepower.

(2) Any single internal combustion engine with a maximum rating of less than one thousand brake horsepower, or multiple engines with a combined brake horsepower rating of less than one thousand brake horsepower, and which operates a total of five hundred hours or less in a rolling twelve-month period.

(3) Any internal combustion engine, or multiple engines at the same facility, with a total combined actual emission rate of five tons [4.54 metric tons] per year or less of any air contaminant for which an ambient air quality standard has been promulgated in section 33-15-02-04.

(4) The exemptions listed in paragraphs 1, 2, and 3 do not apply to engines that are a utility unit as defined in section 33-15-21-08.1 or are subject to a standard under chapter 33-15-22.

d. Bench scale laboratory equipment used exclusively for chemical or physical analysis or experimentation.

e. Portable brazing, soldering, or welding equipment.

f. The following equipment:

(1) Comfort air-conditioners or comfort ventilating systems which are not designed and not intended to be used to remove emissions generated by or released from specific units or equipment.

(2) Water cooling towers and water cooling ponds unless used for evaporative cooling of process water, or for evaporative cooling of water from barometric jets or barometric condensers or used in conjunction with an installation requiring a permit.

(3) Equipment used exclusively for steam cleaning.

(4) Porcelain enameling furnaces or porcelain enameling drying ovens.

(5) Unheated solvent dispensing containers or unheated solvent rinsing containers of sixty gallons [227.12 liters] capacity or less.

(6) Equipment used for hydraulic or hydrostatic testing.

g. The following equipment or any exhaust system or collector serving exclusively such equipment:

   (1) Blast cleaning equipment using a suspension of abrasive in water.

   (2) Bakery ovens if the products are edible and intended for human consumption.

   (3) Kilns for firing ceramic ware, heated exclusively by gaseous fuels, singly or in combinations, and electricity.

   (4) Confection cookers if the products are edible and intended for human consumption.

   (5) Drop hammers or hydraulic presses for forging or metalworking.

   (6) Diecasting machines.

   (7) Photographic process equipment through which an image is reproduced upon material through the use of sensitized radiant energy.

   (8) Equipment for drilling, carving, cutting, routing, turning, sawing, planing, spindle sanding, or disc sanding of wood or wood products, which is located within a facility that does not vent to the outside air.

   (9) Equipment for surface preparation of metals by use of aqueous solutions, except for acid solutions.

   (10) Equipment for washing or drying products fabricated from metal or glass; provided, that no volatile organic materials are used in the process and that no oil or solid fuel is burned.

   (11) Laundry dryers, extractors, or tumblers for fabrics cleaned with only water solutions of bleach or detergents.

h. Natural draft hoods or natural draft ventilators.

i. Containers, reservoirs, or tanks used exclusively for:

   (1) Dipping operations for coating objects with oils, waxes, or greases, if no organic solvents are used.

   (2) Dipping operations for applying coatings of natural or synthetic resins which contain no organic solvents.

    (3) Storage of butane, propane, or liquefied petroleum or natural gas.

    (4) Storage of lubricating oils.

    (5) Storage of petroleum liquids except those containers, reservoirs, or tanks subject to the requirements of chapter 33-15-12.

j. Gaseous fuel-fired or electrically heated furnaces for heat treating glass or metals, the use of which does not involve molten materials.

k. Crucible furnaces, pot furnaces, or induction furnaces, with a capacity of one thousand pounds [453.59 kilograms] or less each, unless otherwise noted, in which no sweating or distilling is conducted, nor any fluxing conducted utilizing chloride, fluoride, or ammonium compounds, and from which only the following metals are poured or in which only the following metals are held in a molten state:

    (1) Aluminum or any alloy containing over fifty percent aluminum; provided, that no gaseous chlorine compounds, chlorine, aluminum chloride, or aluminum fluoride are used.

    (2) Magnesium or any alloy containing over fifty percent magnesium.

    (3) Lead or any alloy containing over fifty percent lead, in a furnace with a capacity of five hundred fifty pounds [249.48 kilograms] or less.

    (4) Tin or any alloy containing over fifty percent tin.

    (5) Zinc or any alloy containing over fifty percent zinc.

    (6) Copper.

    (7) Precious metals.

l. Open burning activities within the scope of section 33-15-04-02.

m. Flares used to indicate some danger to the public.

n. Sources or alterations to a source which are of minor significance as determined by the department.

o. Oil and gas production facilities as defined in chapter 33-15-20 which are not a major source as defined in subsection 1 of section 33-15-14-06.

14. **Performance and emission testing.**

    a. Emission tests or performance tests or both shall be conducted by the owner or operator of a facility and data reduced in accordance with the applicable procedure, limitations, standards, and test methods established by this article. Such tests must be conducted under the owner's or operator's permit to construct, and such permit is subject to the faithful completion of the test in accordance with this article.

    b. All dates and periods of trial operation for the purpose of performance or emission testing pursuant to a permit to construct must be approved in advance by the department. Trial operation shall cease if the department determines, on the basis of the test results, that continued operation will result in the violation of this article. Upon completion of any test conducted under a permit to construct, the department may order the cessation of the operation of the tested equipment or facility until such time as a permit to operate has been issued by the department.

    c. Upon review of the performance data resulting from any test, the department may require the installation of such additional control equipment as will bring the facility into compliance with this article.

    d. Nothing in this article may be construed to prevent the department from conducting any test upon its own initiative, or from requiring the owner or operator to conduct any test at such time as the department may determine.

15. **Responsibility to comply.**

    a. Possession of a permit to construct does not relieve any person of the responsibility to comply with this article.

    b. The exemption of any stationary source from the requirements of a permit to construct by reason of inclusion in subsection 13 does not relieve the owner or operator of such source of the responsibility to comply with any other applicable portions of this article.

16. **Portable sources.** Sources which are designated to be portable and which are not subject to the requirements of chapter 33-15-15 are exempt from requirements to obtain a permit to construct. The owner or operator shall submit an application for a permit to operate prior to initiating operations.

17. **Registration of exempted stationary sources.** The department may require that the owner or operator of any stationary source exempted under subsection 13 shall register the source with the department within such time limits and on such forms as the department may prescribe.

18. **Extensions of time.** The department may extend any of the time periods specified in subsections 4, 5, and 6 upon notification of the applicant by the department.

19. **Amendment of permits.** The department may, when the public interest requires or when necessary to ensure the accuracy of the permit, modify any condition or information contained in the permit to construct. Modification shall be made only upon the department's own motion and the procedure shall, at a minimum, conform to any requirements of federal and state law. In the event that the modification would be a major modification as defined in chapter 33-15-15, the department shall follow the procedures established in chapter 33-15-15. For those of concern to the public, the department will provide:

    a. Reasonable notice to the public, in the area to be affected, of the opportunity for comment on the proposed modification, and the opportunity for a public hearing, upon request, as well as written public comment.

    b. A minimum of a thirty-day period for written public comment, with the opportunity for a public hearing during that thirty-day period, upon request.

    c. Consideration by the department of all comments received in its order for modification.

    The department may require the submission of such maps, plans, specifications, emission information, and compliance schedules as it deems necessary prior to the issuance of an amendment. It is the intention of the department that this subsection shall apply only in those instances allowed by federal rules and regulations and only in those instances in which the granting of a variance pursuant to section 33-15-01-06 and enforcement of existing permit conditions are manifestly inappropriate.

History: Amended effective March 1, 1980; February 1, 1982; October 1, 1987; June 1, 1990; March 1, 1994; August 1, 1995; September 1, 1997; September 1, 1998; June 1, 2001; March 1, 2003; February 1, 2005; January 1, 2007; April 1, 2009.
General Authority: NDCC 23-25-03, 23-25-04, 23-25-04.1, 23-25-04.2
Law Implemented: NDCC 23-25-04, 23-25-04.1, 23-25-04.2

33-15-14-03. Minor source permit to operate.

1. **Permit to operate required.**

    a. Except as provided in subdivisions c and d, no person may operate or cause the routine operation of an installation or source designated in section 33-15-14-01 without applying for and obtaining, in accordance with this section, a permit to operate. Application for a permit to operate a new installation or source must be made at least thirty days prior to startup of routine operation. Those sources that received a permit to construct under section 33-15-14-02, need only submit a thirty-day prior notice of proposed startup to satisfy the requirement to apply for a permit to operate under this subdivision.

b. No person may operate or cause the operation of an installation or source in violation of any permit to operate or any condition imposed upon a permit to operate or in violation of this article.

c. Sources that are subject to the title V permitting requirements of section 33-15-14-06 are exempt from the requirements of this section except during the transitional period from a minor source permit to operate to a title V permit to operate. Existing sources shall comply with all the requirements of this section until a title V permit to operate is issued. Fees for sources that meet the applicability requirements of section 33-15-14-06 shall be assessed based on section 33-15-23-04.

d. Sources that are exempt from the requirement to obtain a permit to construct under subsection 13 of section 33-15-14-02 are exempt from this section.

e. Sources which are subject to the title V permitting requirements in section 33-15-14-06 based solely on their potential to emit may apply for a federally enforceable minor source permit to operate which would limit their potential to emit to a level below the title V permit to operate applicability threshold.

f. Permits which are issued under this section which do not conform to the requirements of this section, including public participation under subdivision a of subsection 5 of section 33-15-14-03, and the requirements of any United States environmental protection agency regulations may be deemed not federally enforceable by the United States environmental protection agency.

g. General permits: The department may issue a general permit covering numerous similar sources. Any general permit shall comply with all requirements applicable to other minor source permits to operate and shall identify criteria by which sources may qualify for the general permit. To sources that qualify, the department shall grant the conditions and terms of the general permit. Sources that would qualify for a general permit must apply to the department for coverage under the terms of the general permit or apply for an individual minor source permit to operate. Without repeating the public participation procedures under subsection 5 of section 33-15-14-03, the department may grant a source's request for authorization to operate under a general permit.

2. **Application for permit to operate.**

   a. Application for a permit to operate must be made by the owner or operator thereof on forms furnished by the department.

   b. Each application for a permit to operate must be accompanied by such performance tests results, information, and records as may be required by the department to determine whether the requirements of this article will be met. Such information may also be required by the department at any time when the source is being operated to determine compliance with this article.

   c. Each application must be signed by the applicant, which signature shall constitute an agreement that the applicant will assume responsibility for the operation of the installation or source in accordance with this article.

3. **Standards for granting permits to operate.** No permit to operate may be granted unless the applicant shows to the satisfaction of the department that the source is in compliance with this article.

4. **Performance testing.**

   a. Before a permit to operate is granted, the applicant, if required by the department, shall conduct performance tests in accordance with methods and procedures required by this article or methods and procedures approved by the department. Such tests must be made at the expense of the applicant. The department may monitor such tests and may also conduct performance tests.

   b. Emission tests or performance tests or both shall be conducted by the owner or operator of a facility and data reduced in accordance with the applicable procedure, limitations, standards, and test methods established by this article. Issuance of a minor source permit to operate is subject to the faithful completion of the test in accordance with this article.

   c. All dates and periods of trial operation for the purpose of performance or emission testing pursuant to a permit to operate must be approved in advance by the department. Trial operation shall cease if the department determines, on the basis of the test results, that continued operation will result in the violation of this article. Upon completion of any test conducted under a permit to construct, the department may order the cessation of the operation of the tested equipment or facility until such time as a permit to operate has been issued by the department.

d. Upon review of the performance data resulting from any test, the department may require the installation of such additional control equipment as will bring the facility into compliance with this article.

e. Nothing in this article may be construed to prevent the department from conducting any test upon its own initiative or from requiring the owner or operator to conduct any test at such time as the department may determine.

5. **Action on applications.**

a. Public participation: This subdivision is applicable to only those sources which apply for a federally enforceable minor source permit to operate which limits their potential to emit an air contaminant. The department shall:

(1) Within ninety days of receipt of a complete application:

(a) Make a preliminary determination concerning issuance of the permit to operate.

(b) Make available in at least one location in the county or counties in which the source is located, a copy of the proposed permit and copies of or a summary of the information considered in developing the permit.

(c) Publish notice to the public by prominent advertisement, in the region affected, of the opportunity for written comment on the proposed permit. The public notice must include the proposed location of the source.

(d) Deliver a copy of the proposed permit and public notice to any state or federal land manager, or Indian governing body whose lands will be significantly affected by the source's emissions. For purposes of this subparagraph, lands will be considered to be significantly affected if the source is located within thirty-one and seven hundredths miles [50 kilometers] of such land.

(e) Provide a copy of the proposed permit, all information considered in the development of the permit and the public notice to the regional administrator of the United States environmental protection agency.

(2) Allow thirty days for public comment.

(3) Consider all public comments properly received, in making the final decision on the application.

(4) Allow the applicant to submit written responses to public comments received by the department. The applicant's responses must be submitted to the department within twenty days of the close of the public comment period.

(5) Take final action on the application within thirty days of the applicant's response to the public comments.

(6) Provide a copy of the final permit, if issued, to the applicant, the regional administrator of the United States environmental protection agency, and anyone who requests a copy.

b. For those sources not subject to public participation under subdivision a, the department shall act within thirty days after receipt of an application for a permit to operate a new installation or source, and within thirty days after receipt of an application to operate an existing installation or source, and shall notify the applicant, in writing, of the approval, conditional approval, or denial of the application.

c. The department shall set forth in any notice of denial the reasons for denial. A denial must be without prejudice to the applicant's right to a hearing before the department or for filing a further application after revisions are made to meet objections specified as reasons for the denial.

6. **Permit to operate - Conditions.** The department may impose any reasonable conditions upon a permit to operate. All emission limitations, controls, and other requirements imposed by conditions on the permit to operate must be at least as stringent as any applicable limitation or requirement contained in this article. Permit to operate conditions may include:

a. Sampling, testing, and monitoring of the facilities or ambient air or both.

b. Trial operation and performance testing.

c. Prevention and abatement of nuisance conditions caused by operation of the facility.

d. Recordkeeping and reporting.

e. Compliance with applicable rules and regulations in accordance with a compliance schedule.

f. Limits on the hours of operation of a source or its processing rate, fuel usage, or production rate when necessary to assure compliance with this article.

7. **Suspension or revocation of permit to operate.**

   a. The department may suspend or revoke a permit to operate for violation of this article, violations of a permit condition, or failure to respond to a notice of violation or any order issued pursuant to this article.

   b. Suspension or revocation of a permit to operate shall become final ten days after serving notice on the holder of the permit.

   c. A permit to operate which has been revoked pursuant to this article must be surrendered forthwith to the department.

   d. No person may operate or cause the operation of an installation or source if the department denies or revokes a permit to operate.

8. **Transfer of permit to operate.** The holder of a permit to operate may not transfer it without the prior approval of the department.

9. **Renewal of permit to operate.**

   a. Every permit to operate issued by the department after February 9, 1976, shall become void upon the fifth anniversary of its issuance. Applications for renewal of such permits must be submitted ninety days prior to such anniversary date. The department shall approve or disapprove such application within ninety days. If a source submits a complete application for a permit renewal at least ninety days prior to the expiration date, the source's failure to have a minor source permit to operate is not a violation of this section until the department takes final action on the renewal application.

   b. The department may amend permits issued prior to February 9, 1976, so as to provide for voidance upon the fifth anniversary of its issuance.

10. **[Reserved]**

11. **[Reserved]**

12. **Responsibility to comply.**

   a. Possession of a minor source permit to operate does not relieve any person of the responsibility to comply with this article.

b. The exemption of any stationary source from the requirements to obtain a minor source permit to operate does not relieve the owner or operator of such source of the responsibility to comply with any other applicable portions of this article.

13. **Portable sources.** Sources which are designed to be portable and which are operated at temporary jobsites across the state may not be considered a new source by virtue of location changes. One application for a permit to operate any portable source may be filed in accordance with this chapter, and subsequent applications are not required for each temporary jobsite. The permit to operate issued by the department shall be conditioned by such specific requirements as the department deems appropriate to carry out the provisions of sections 33-15-01-07 and 33-15-01-15.

14. **Registration of exempted stationary sources.** The department may require that the owner or operator of any stationary source exempted from the requirement to obtain a minor source permit to operate to register the source with the department within such time limits and on such forms as the department may prescribe.

15. **Extensions of time.** The department may extend any of the time periods specified in this section upon notification of the applicant by the department.

16. **Amendment of permits.** When the public interest requires or when necessary to ensure the accuracy of the permit, the department may modify any condition or information contained in a minor source permit to operate. Modification shall be made only upon the department's own motion and the procedure shall, at a minimum, conform to any requirements of federal and state law. In the event that the modification would be a major modification as defined in chapter 33-15-15, the department shall follow the procedures established in chapter 33-15-15. For those of concern to the public, or modify a condition which limits the potential to emit of a source which possesses a federally enforceable permit, the department will provide:

    a. Reasonable notice to the public, in the area to be affected, of the opportunity for comment on the proposed modification and the opportunity for a public hearing, upon request, as well as written public comment.

    b. A minimum of a thirty-day period for written public comment with the opportunity for a public hearing during that thirty-day period, upon request.

    c. Consideration by the department of all comments received.

The department may require the submission of such maps, plans, specifications, emission information, and compliance schedules as it deems necessary prior to the issuance of an amendment. It is the intention of the department that this subsection shall apply only in those instances allowed by federal rules and regulations and only in those instances in which the granting of a variance pursuant to section 33-15-01-06 and enforcement of existing permit conditions are manifestly inappropriate.

History: Amended effective February 1, 1982; October 1, 1987; March 1, 1994; August 1, 1995; June 1, 2001; March 1, 2003.
General Authority: NDCC 23-25-03, 23-25-04.1, 23-25-04.2
Law Implemented: NDCC 23-25-03, 23-25-04.1, 23-25-04.2

33-15-14-04. Permit fees. Repealed effective March 1, 1994.

33-15-14-05. Common provisions applicable to both permit to construct and permit to operate. Repealed effective March 1, 1994.

33-15-14-06. Title V permit to operate.

1. **Definitions.** For purposes of this section:

   a. "Affected source" means any source that includes one or more affected units.

   b. "Affected state" means any state that is contiguous to North Dakota whose air quality may be affected by a source subject to a proposed title V permit, permit modification, or permit renewal or which is within fifty miles [80.47 kilometers] of the permitted source.

   c. "Affected unit" means a unit that is subject to any acid rain emissions reduction requirement or acid rain emissions limitation under title IV of the Federal Clean Air Act.

   d. "Applicable requirement" means all of the following as they apply to emissions units at a source that is subject to requirements of this section (including requirements that have been promulgated or approved by the United States environmental protection agency through rulemaking at the time of issuance but have future-effective compliance dates):

      (1) Any standard or other requirement provided for in the North Dakota state implementation plan approved or promulgated by the United States environmental protection agency through rulemaking under title I of the Federal Clean Air Act that implements the relevant requirements of the Federal Clean Air Act, including any revisions to that plan.

(2) Any term or condition of any permit to construct issued pursuant to this chapter.

(3) Any standard or other requirement under section 111 including section 111(d) of the Federal Clean Air Act.

(4) Any standard or other requirement under section 112 of the Federal Clean Air Act including any requirement concerning accident prevention under section 112(r)(7) of the Federal Clean Air Act.

(5) Any standard or other requirement of the acid rain program under title IV of the Federal Clean Air Act.

(6) Any requirements established pursuant to section 504(b) or section 114(a)(3) of the Federal Clean Air Act.

(7) Any standard or other requirement governing solid waste incineration, under section 129 of the Federal Clean Air Act.

(8) Any standard or other requirement for consumer and commercial products, under section 183(e) of the Federal Clean Air Act.

(9) Any standard or other requirement for tank vessels under section 183(f) of the Federal Clean Air Act.

(10) Any standard or other requirement of the program to control air pollution from outer continental shelf sources, under section 328 of the Federal Clean Air Act.

(11) Any standard or other requirement of the regulations promulgated to protect stratospheric ozone under title VI of the Federal Clean Air Act, unless the administrator of the United States environmental protection agency has determined that such requirements need not be contained in a title V permit.

(12) Any national ambient air quality standard or increment or visibility requirement under part C of title I of the Federal Clean Air Act, but only as it would apply to temporary sources permitted pursuant to section 504(e) of the Federal Clean Air Act.

e. "Designated representative" means a responsible natural person authorized by the owners and operators of an affected source and of all affected units at the source, as evidenced by a certificate of representation submitted in accordance with subpart B of 40 CFR 72, to represent and legally bind each owner and operator, as a matter of federal law, in matters pertaining to the acid rain program. Whenever the term "responsible official" is used in this section, or in any other regulations implementing title V of the Federal Clean Air Act, it shall be deemed to refer to the "designated representative" with regard to all matters under the acid rain program.

f. "Draft permit" means the version of a permit for which the department offers public participation or affected state review.

g. "Emergency" means any situation arising from sudden and reasonably unforeseeable events beyond the control of the source, including acts of God, which situation requires immediate corrective action to restore normal operation, and that causes the source to exceed a technology-based emission limitation under the title V permit to operate, due to unavoidable increases in emissions attributable to the emergency. An emergency shall not include noncompliance to the extent caused by improperly designed equipment, lack of preventive maintenance, careless or improper operation, or operator error.

h. "Emissions allowable under the permit" means a federally enforceable permit term or condition determined at issuance to be required by an applicable requirement that establishes an emissions limit (including a work practice standard) or a federally enforceable emissions cap that the source has assumed to avoid an applicable requirement to which the source would otherwise be subject.

i. "Emissions unit" means any part or activity of a stationary source that emits or has the potential to emit any regulated air contaminant or any contaminant listed under section 112(b) of the Federal Clean Air Act. This term does not alter or affect the definition of unit for purposes of title IV of the Federal Clean Air Act.

j. "Environmental protection agency" or the "administrator" means the administrator of the United States environmental protection agency or the administrator's designee.

k. "Federal Clean Air Act" means the Federal Clean Air Act, as amended [42 U.S.C. 7401 et seq.].

l. "Final permit" means the version of a title V permit issued by the department that has completed all review procedures required in this section.

m. "Fugitive emissions" are those emissions which could not reasonably pass through a stack, chimney, vent, or other functionally equivalent opening.

n. "General permit" means a title V permit to operate that meets the requirements of subdivision d of subsection 5.

o. "Major source" means any stationary source (or any group of stationary sources that are located on one or more contiguous or adjacent properties, and are under common control of the same person (or persons under common control)) belonging to a single major industrial grouping and that are described in paragraph 1 or 2. For the purposes of defining "major source", a stationary source or group of stationary sources shall be considered part of a single industrial grouping if all of the contaminant emitting activities at such source or group of sources on contiguous or adjacent properties belong to the same major group (i.e., all have the same two-digit code) as described in the standard industrial classification manual, 1987.

(1) A major source under section 112 of the Federal Clean Air Act, which is defined as:

(a) For contaminants other than radionuclides, any stationary source or group of stationary sources located within a contiguous area and under common control that emits or has the potential to emit, in the aggregate, ten tons [9.07 metric tons] per year (tpy) or more of any hazardous air contaminant which has been listed pursuant to section 112(b) of the Federal Clean Air Act, twenty-five tons [22.67 metric tons] per year or more of any combination of such hazardous air contaminants, or such lesser quantity as the administrator of the United States environmental protection agency may establish by rule. Notwithstanding the preceding sentence, emissions from any oil or gas exploration or production well (with its associated equipment) and emissions from any pipeline compressor pump station shall not be aggregated with emissions from other similar units, whether or not such units are in a contiguous area or under common control, to determine whether such units or stations are major sources.

(b) For radionuclides, "major source" shall have the meaning specified by the administrator of the United States environmental protection agency by rule.

(2) A major stationary source of air contaminants, that directly emits or has the potential to emit, one hundred tons [90.68 metric tons] per year or more of any air contaminant (including any major source of fugitive emissions of any such contaminant, as determined by rule by the administrator of the United States environmental protection agency).

The fugitive emissions of a stationary source shall not be considered in determining whether it is a major stationary source for the purposes of this section, unless the source belongs to one of the following categories of stationary source:

(a) Coal cleaning plants (with thermal dryers).

(b) Kraft pulp mills.

(c) Portland cement plants.

(d) Primary zinc smelters.

(e) Iron and steel mills.

(f) Primary aluminum ore reduction plants.

(g) Primary copper smelters.

(h) Municipal incinerators capable of charging more than two hundred fifty tons [226.80 metric tons] of refuse per day.

(i) Hydrofluoric, sulfuric, or nitric acid plants.

(j) Petroleum refineries.

(k) Lime plants.

(l) Phosphate rock processing plants.

(m) Coke oven batteries.

(n) Sulfur recovery plants.

(o) Carbon black plants (furnace process).

(p) Primary lead smelters.

(q) Fuel conversion plants.

(r) Sintering plants.

(s) Secondary metal production plants.

(t) Chemical process plants.

(u) Fossil-fuel boilers (or combination thereof) totaling more than two hundred fifty million British thermal units per hour heat input.

(v) Petroleum storage and transfer units with a total storage capacity exceeding three hundred thousand barrels.

(w) Taconite ore processing plants.

(x) Glass fiber processing plants.

(y) Charcoal production plants.

(z) Fossil-fuel-fired steam electric plants of more than two hundred fifty million British thermal units per hour heat input.

(aa) Any other stationary source category which as of August 7, 1980, is being regulated under section 111 or 112 of the Federal Clean Air Act.

p. "Permit modification" means a revision to a title V permit that meets the requirements of subdivision e of subsection 6.

q. "Permit program costs" means all reasonable (direct and indirect) costs required to develop and administer a permit program, under this section (whether such costs are incurred by the department or other state or local agencies that do not issue permits directly, but that support permit issuance or administration).

r. "Permit revision" means any permit modification or administrative permit amendment.

s. "Potential to emit" means the maximum capacity of a stationary source to emit any air contaminant under its physical and operational design. Any physical or operational limitation on the capacity of a source to emit an air contaminant, including air pollution control equipment and restrictions on hours of operation or on the type or amount of material combusted, stored, or processed, shall be treated as part of its design if the limitation is enforceable by the administrator of the United States environmental protection agency and the department.

t. "Proposed permit" means the version of a permit that the department proposes to issue and forwards to the administrator of the United States environmental protection agency for review.

u. "Regulated air contaminant" means the following:

(1) Nitrogen oxides or any volatile organic compounds.

(2) Any contaminant for which a national ambient air quality standard has been promulgated.

(3) Any contaminant that is subject to any standard promulgated under section 111 of the Federal Clean Air Act.

(4) Any class I or II substance subject to a standard promulgated under or established by title VI of the Federal Clean Air Act.

(5) Any contaminant subject to a standard promulgated under section 112 or other requirements established under section 112 of the Federal Clean Air Act, including sections 112(g), (j), and (r) of the Federal Clean Air Act, including the following:

    (a) Any contaminant subject to requirements under section 112(j) of the Federal Clean Air Act. If the administrator fails to promulgate a standard by the date established pursuant to section 112(e) of the Federal Clean Air Act, any contaminant for which a subject source would be major shall be considered to be regulated on the date eighteen months after the applicable date established pursuant to section 112(e) of the Federal Clean Air Act; and

    (b) Any contaminant for which the requirements of section 112(g)(2) of the Federal Clean Air Act have been met, but only with respect to the individual source subject to section 112(g)(2) of the Federal Clean Air Act requirement.

v. "Regulated contaminant" for fee calculation, which is used only for chapter 33-15-23, means any "regulated air contaminant" except the following:

(1) Carbon monoxide.

(2) Any contaminant that is a regulated air contaminant solely because it is a class I or II substance subject to a standard promulgated under or established by title VI of the Federal Clean Air Act.

(3) Any contaminant that is a regulated air contaminant solely because it is subject to a standard or regulation under section 112(r) of the Federal Clean Air Act.

w. "Renewal" means the process by which a permit is reissued at the end of its term.

x. "Responsible official" means one of the following:

(1) For a corporation: a president, secretary, treasurer, or vice president of the corporation in charge of a principal business function, or any other person who performs similar policy or decisionmaking functions for the corporation, or a duly authorized representative of such person if the representative is responsible for the overall operation of one or more manufacturing, production, or operating facilities applying for or subject to a permit and either:

(a) The facilities employ more than two hundred fifty persons or have gross annual sales or expenditures exceeding twenty-five million dollars (in second quarter 1980 dollars).

(b) The delegation of authority to such representatives is approved in advance by the department.

(2) For a partnership or sole proprietorship: a general partner or the proprietor, respectively.

(3) For a municipality, state, federal, or other public agency: either a principal executive officer or ranking elected official. For the purposes of this section, a principal executive officer of a federal agency includes the chief executive officer having responsibility for the overall operations of a principal geographic unit of the agency (e.g., a regional administrator of the United States environmental protection agency).

(4) For affected sources:

(a) The designated representative insofar as actions, standards, requirements, or prohibitions under title IV of the Federal Clean Air Act or the regulations promulgated thereunder are concerned.

(b) The designated representative for any other purposes under this section.

y. "Section 502(b)(10) changes" are changes that contravene an express permit term. Such changes do not include changes that would violate applicable requirements or contravene federally enforceable permit terms and conditions that are monitoring (including test methods), recordkeeping, reporting, or compliance certification requirements.

z. "Stationary source" means any building, structure, facility, or installation that emits or may emit any regulated air contaminant or any contaminant listed under section 112(b) of the Federal Clean Air Act.

aa. "Title V permit to operate or permit" (unless the context suggests otherwise) means any permit or group of permits covering a source that is subject to this section that is issued, renewed, amended, or revised pursuant to this section.

bb. "Title V source" means any source subject to the permitting requirements of this section, as provided in subsection 2.

2. **Applicability.**

a. This section is applicable to the following sources:

(1) Any major source.

(2) Any source, including an area source, subject to a standard, limitation, or other requirement under section 111 of the Federal Clean Air Act.

(3) Any source, including an area source, subject to a standard or other requirement under section 112 of the Federal Clean Air Act, except that a source is not required to obtain a permit solely because it is subject to regulations or requirements under section 112(r) of the Federal Clean Air Act.

(4) Any affected source.

(5) Any source in a source category designated by the administrator of the United States environmental protection agency.

b. The following source categories are exempt from the requirements of this section:

(1) All sources listed in subdivision a that are not major sources, affected sources, or solid waste incineration units required to obtain a permit pursuant to section 129(e) of the Federal Clean Air Act, are exempt from the obligation to obtain a title V permit until such time as the administrator of the United States environmental protection agency completes a rulemaking to determine how the program should be structured for nonmajor sources and the appropriateness of any permanent exemptions.

(2) In the case of nonmajor sources subject to a standard or other requirement under either section 111 or 112 of the Federal Clean Air Act after July 21, 1992, those the

administrator of the United States environmental protection agency determines to be exempt from the requirement to obtain a title V source permit at the time that the new standard is promulgated.

(3) Any source listed as exempt from the requirement to obtain a permit under this section may opt to apply for a title V permit. Sources that are exempted by paragraphs 1 and 2 and which do not opt to apply for a title V permit to operate are subject to the requirements of section 33-15-14-03.

(4) The following source categories are exempted from the obligation to obtain a permit under this section.

(a) All sources and source categories that would be required to obtain a permit solely because they are subject to 40 CFR 60, subpart AAA - standards of performance for new residential wood heaters.

(b) All sources and source categories that would be required to obtain a permit solely because they are subject to 40 CFR 61, subpart M - national emission standard for hazardous air pollutants for asbestos, section 61.145, standard for demolition and renovation.

c. For major sources, the department will include in the permit all applicable requirements for all relevant emissions units in the major source.

For any nonmajor source subject to the requirements of this section, the department will include in the permit all applicable requirements applicable to the emissions units that cause the source to be subject to this section.

d. Fugitive emissions from a source subject to the requirements of this section shall be included in the permit application and the permit in the same manner as stack emissions, regardless of whether the source category in question is included in the list of sources contained in the definition of major source.

3. **Scope.** Nothing within this section shall relieve the owner or operator of a source of the requirement to obtain a permit to construct under section 33-15-14-02 or to comply with any other applicable standard or requirement of this article.

4. **Permit applications.**

a. Duty to apply. For each title V source, the owner or operator shall submit a timely and complete permit application in accordance with this subdivision.

(1) Timely application.

(a) A timely application for a source applying for a title V permit for the first time is one that is submitted within one year of the source becoming subject to this section.

(b) Title V sources required to meet the requirements under section 112(g) of the Federal Clean Air Act, or to have a permit to construct under section 33-15-14-02, shall file a complete application to obtain the title V permit or permit revision within twelve months after commencing operation. Where an existing title V permit would prohibit such construction or change in operation, the source must obtain a permit revision before commencing operation.

(c) For purposes of permit renewal, a timely application is one that is submitted at least six months, but not more than eighteen months, prior to the date of permit expiration.

(2) Complete application. To be deemed complete, an application must provide all information required pursuant to subdivision c, except that applications for a permit revision need supply such information only if it is related to the proposed change. Information required under subdivision c must be sufficient to evaluate the subject source and its application and to determine all applicable requirements. A responsible official must certify the submitted information consistent with subdivision d. Unless the department determines that an application is not complete within sixty days of receipt of the application, such application shall be deemed to be complete, except as otherwise provided in paragraph 3 of subdivision a of subsection 6. If, while processing an application that has been determined or deemed to be complete, the department determines that additional information is necessary to evaluate or take final action on that application, it may request such information in writing and set a reasonable deadline for a response. The source's ability to operate without a permit, as set forth in subdivision b of subsection 6, shall be in effect from the date the application is determined or deemed to be complete until the final permit is issued, provided that the applicant

submits any requested additional information by the deadline specified by the department.

(3) Confidential information. If a source has submitted information to the department under a claim of confidentiality, the source must also submit a copy of such information directly to the administrator of the United States environmental protection agency when directed to do so by the department.

b. Duty to supplement or correct application. Any applicant who fails to submit any relevant facts or who has submitted incorrect information in a permit application shall, upon becoming aware of such failure or incorrect submittal, promptly submit such supplementary facts or corrected information. In addition, an applicant shall provide additional information as necessary to address any requirements that become applicable to the source after the date it filed a complete application but prior to release of a draft permit.

c. Standard application form and required information. All applications for a title V permit to operate shall be made on forms supplied by the department. Information as described below for each emissions unit at a title V source shall be included in the application. Detailed information for emissions units or activities that have the potential to emit less than the following quantities of air contaminants (insignificant units or activities) need not be included in permit applications:

Particulate: 2 tons [1.81 metric tons] per year

Inhalable particulate: 2 tons [1.81 metric tons] per year

Sulfur dioxide: 2 tons [1.81 metric tons] per year

Hydrogen sulfide: 2 tons [1.81 metric tons] per year

Carbon monoxide: 2 tons [1.81 metric tons] per year

Nitrogen oxides: 2 tons [1.81 metric tons] per year

Ozone: 2 tons [1.81 metric tons] per year

Reduced sulfur compounds: 2 tons [1.81 metric tons] per year

Volatile organic compounds: 2 tons [1.81 metric tons]

All other regulated contaminants including those in section 112(b) of the Federal Clean Air Act: 0.5 tons [0.45 metric tons] per year.

Where a contaminant could be placed in more than one category, the smallest emission level applies.

However, for insignificant activities or emissions units, a list of such activities or units must be included in the application. An applicant may not omit information needed to determine the applicability of, or to impose, any applicable requirement, or to evaluate the fee amount required under section 33-15-23-04. The application, shall, as a minimum, include the elements specified below:

(1) Identifying information, including company name and address (or plant name and address if different from the company name), owner's name and agent, and telephone number and names of plant site manager or contact.

(2) A description of the source's processes and products (by Standard Industrial Classification Code) including any associated with each alternate scenario identified by the source.

(3) The following emissions-related information:

  (a) All emissions of contaminants for which the source is major, and all emissions of regulated air contaminants. A permit application shall describe all emissions of regulated air contaminants emitted from any emissions unit, except when such units are exempted under this subdivision.

  (b) Identification and description of all points of emissions described in subparagraph a in sufficient detail to establish the basis for fees and applicability of requirements of the Federal Clean Air Act and this article.

  (c) Emissions rates in tons per year, in terms of the applicable standard, and terms that are necessary to establish compliance with the applicable compliance method.

  (d) Fuels, fuel use, raw materials, production rates, and operating schedules.

  (e) Identification and description of air pollution control equipment and compliance monitoring devices or activities.

(f) Limitations on source operation affecting emissions or any work practice standards, when applicable, for all regulated contaminants.

(g) Other information required by any applicable requirement including information related to stack height limitations developed pursuant to chapter 33-15-18.

(h) Calculations on which the information in subparagraphs a through g is based.

(4) The following air pollution control requirements:

(a) Citation and description of all applicable requirements; and

(b) Description of or reference to any applicable test method for determining compliance with each applicable requirement.

(5) Other specific information that may be necessary to implement and enforce other applicable requirements of the Federal Clean Air Act or of this article or to determine the applicability of such requirements.

(6) An explanation of any proposed exemptions from otherwise applicable requirements.

(7) Information that the department determines to be necessary to define alternative operating scenarios identified by the source or to define permit terms and conditions.

(8) A compliance plan for all title V sources that contains all the following:

(a) A description of the compliance status of the source with respect to all applicable requirements.

(b) A description as follows:

[1] For applicable requirements with which the source is in compliance, a statement that the source will continue to comply with such requirements.

[2] For applicable requirements that will become effective during the permit term, a statement that

the source will meet such requirements on a timely basis.

[3] For requirements for which the source is not in compliance at the time of permit issuance, a narrative description of how the source will achieve compliance with such requirements.

(c) A compliance schedule as follows:

[1] For applicable requirements with which the source is in compliance, a statement that the source will continue to comply with such requirements.

[2] For applicable requirements that will become effective during the permit term, a statement that the source will meet such requirements on a timely basis. A statement that the source will meet in a timely manner applicable requirements that become effective during the permit term shall satisfy this provision, unless a more detailed schedule is expressly required by the applicable requirement.

[3] A schedule of compliance for sources that are not in compliance with all applicable requirements at the time of permit issuance. Such a schedule shall include a schedule of remedial measures, including an enforceable sequence of actions with milestones, leading to compliance with any applicable requirements for which the source will be in noncompliance at the time of permit issuance. This compliance schedule shall resemble and be at least as stringent as that contained in any judicial consent decree or administrative order to which the source is subject. Any such schedule of compliance shall be supplemental to, and shall not sanction noncompliance with, the applicable requirements on which it is based.

(d) A schedule for submission of certified progress reports no less frequently than every six months for sources required to have a schedule of compliance to remedy a violation.

(e) The compliance plan content requirements specified in this paragraph shall apply and be included in the acid rain portion of a compliance plan for an affected source, except as specifically superseded by regulations promulgated under title IV of the Federal Clean Air Act with regard to the schedule and method or methods the source will use to achieve compliance with the acid rain emissions limitations.

(9) Requirements for compliance certification, including the following:

(a) A certification of compliance with all applicable requirements by a responsible official consistent with subdivision d and section 114(a)(3) of the Federal Clean Air Act;

(b) A statement of methods used for determining compliance, including a description of monitoring, recordkeeping, and reporting requirements and test methods;

(c) A schedule for submission of compliance certifications during the permit term, to be submitted annually, or more frequently if specified by the underlying applicable requirement; and

(d) A statement indicating the source's compliance status with any applicable enhanced monitoring and compliance certification requirements of the Federal Clean Air Act.

(10) The use of nationally standardized forms for acid rain portions of permit applications and compliance plans, as required by regulations promulgated under title IV of the Federal Clean Air Act.

d. Any application form, report, or compliance certification submitted pursuant to these rules shall contain certification by a responsible official of truth, accuracy, and completeness. This certification and any other certification required under this section shall state that, based on information and belief formed after reasonable inquiry, the statements and information in the document are true, accurate, and complete.

5. **Permit content.**

a. Standard permit requirements. Each permit issued under this section shall include, as a minimum, the following elements:

(1) Emissions limitations and standards, including those operational requirements and limitations that assure compliance with all applicable requirements at the time of permit issuance.

  (a) The permit must specify and reference the origin of and authority for each term or condition, and identify any difference in form as compared to the applicable requirement upon which the term or condition is based.

  (b) The permit must state that, if an applicable requirement of the Federal Clean Air Act is more stringent than an applicable requirement of regulations promulgated under title IV of the Federal Clean Air Act, both provisions shall be incorporated into the permit and shall be enforceable by the administrator of the United States environmental protection agency and the department.

  (c) If the state implementation plan allows a determination of an alternative emissions limit at a title V source, equivalent to that contained in the plan, to be made in the permit issuance, renewal, or significant modification process, and the department elects to use such process, any permit containing such equivalency determination shall contain provisions to ensure that any resulting emissions limit has been demonstrated to be quantifiable, accountable, enforceable, and based on replicable procedures.

(2) Permit duration. Each title V permit to operate shall expire upon the fifth anniversary of its issuance.

(3) Monitoring and related recordkeeping and reporting requirements.

  (a) Each permit shall contain the following requirements with respect to monitoring:

    [1] All monitoring and analysis procedures or test methods required under applicable monitoring and testing requirements, including subsection 10 and any procedures and methods promulgated pursuant to sections 504(b) or 114(a)(3) of the Federal Clean Air Act. If more than one monitoring or testing requirement applies, the permit may specify a streamlined set of monitoring or testing provisions provided the specified monitoring or testing is adequate to

assure compliance at least to the same extent as the monitoring or testing applicable requirements that are not included in the permit as a result of such streamlining;

[2] If the applicable requirement does not require periodic testing or instrumental or noninstrumental monitoring (which may consist of recordkeeping designed to serve as monitoring), periodic monitoring sufficient to yield reliable data from the relevant time period that are representative of the source's compliance with the permit, as reported pursuant to subparagraph c. Such monitoring requirements shall assure use of terms, test methods, units, averaging periods, and other statistical conventions consistent with the applicable requirement. Recordkeeping provisions may be sufficient to meet the requirements of this item; and

[3] As necessary, requirements concerning the use, maintenance, and, if appropriate, installation of monitoring equipment or methods.

(b) With respect to recordkeeping, the permit shall incorporate all applicable recordkeeping requirements and require, if applicable, the following:

[1] Records of required monitoring information that include the following:

[a] The date, place as defined in the permit, and time of sampling or measurements;

[b] The dates analyses were performed;

[c] The company or entity that performed the analyses;

[d] The analytical techniques or methods used;

[e] The results of such analyses; and

[f] The operating conditions as existing at the time of sampling or measurement;

[2] Retention of records of all required monitoring data and support information for a period of at

least five years from the date of the monitoring sample, measurement, report, or application. Support information includes all calibration and maintenance records and all original strip-chart recordings for continuous monitoring instrumentation, and copies of all reports required by the permit.

(c) With respect to reporting, the permit shall incorporate all applicable reporting requirements and require the following:

[1] Submittal of reports of any required monitoring at least every six months. All instances of deviations from permit requirements must be clearly identified in such reports. All required reports must be certified by a responsible official consistent with subdivision d of subsection 4.

[2] Prompt reporting of deviations from permit requirements, including those attributable to upset conditions as defined in the permit, the probable cause of such deviations, and any corrective actions or preventive measures taken. The department shall define "prompt" in the permit consistent with chapter 33-15-01 and the applicable requirements.

(4) A permit condition prohibiting emissions exceeding any allowances that the source lawfully holds under title IV of the Federal Clean Air Act or the regulations promulgated thereunder.

(a) No permit revision shall be required for increases in emissions that are authorized by allowances acquired pursuant to title IV of the Federal Clean Air Act, or the regulations promulgated thereunder, provided that such increases do not require a permit revision under any other applicable requirement.

(b) No limit shall be placed on the number of allowances held by the source. The source may not, however, use allowances as a defense to noncompliance with any other applicable requirement.

(c) Any such allowance shall be accounted for according to the procedures established in regulations promulgated under title IV of the Federal Clean Air Act.

(5) A severability clause to ensure the continued validity of the various permit requirements in the event of a challenge to any portions of the permit.

(6) Provisions stating the following:

  (a) The permittee must comply with all conditions of the title V permit. Any permit noncompliance constitutes a violation of the Federal Clean Air Act and this article and is grounds for enforcement action; for permit termination, revocation and reissuance, or modification; or for denial of a permit renewal application.

  (b) It shall not be a defense for a permittee in an enforcement action that it would have been necessary to halt or reduce the permitted activity in order to maintain compliance with the conditions of this permit.

  (c) The permit may be modified, revoked, reopened, and reissued, or terminated for cause. The filing of a request by the permittee for a permit modification, revocation and reissuance, or termination, or of a notification of planned changes or anticipated noncompliance does not stay any permit condition.

  (d) The permit does not convey any property rights of any sort, or any exclusive privilege.

  (e) The permittee must furnish to the department, within a reasonable time, any information that the department may request in writing to determine whether cause exists for modifying, revoking and reissuing, or terminating the permit or to determine compliance with the permit. Upon request, the permittee must also furnish to the department copies of records required to be kept by the permit or, for information claimed to be confidential, the permittee must also furnish such records directly to the administrator of the United States environmental protection agency along with a claim of confidentiality.

(7) A provision to ensure that the source pays fees to the department consistent with the fee schedule in chapter 33-15-23.

(8) Emissions trading. No permit revision shall be required, under any approved economic incentives, marketable permits, emissions trading and other similar programs or

processes for changes that are provided for in the permit and the state implementation plan.

(9) Terms and conditions for reasonably anticipated operating scenarios identified by the source in its application as approved by the department. Such terms and conditions:

  (a) Shall require the source, contemporaneously with making a change from one operating scenario to another, to record in a log at the permitted facility a record of the scenario under which it is operating;

  (b) Shall extend the permit shield described in subdivision f to all terms and conditions under each such operating scenario; and

  (c) Must ensure that the terms and conditions of each such alternative scenario meet all applicable requirements and the requirements of this section.

(10) Terms and conditions, if the permit applicant requests them, for the trading of emissions increases and decreases in the permitted facility, to the extent that the applicable requirements, including the state implementation plan, provide for trading such increases and decreases without a case-by-case approval of each emissions trade. Such terms and conditions:

  (a) Shall include all terms required under subdivisions a and c to determine compliance;

  (b) Shall extend the permit shield described in subdivision f to all terms and conditions that allow such increases and decreases in emissions; and

  (c) Must meet all applicable requirements and requirements of this section.

(11) If a permit applicant requests it, the department shall issue permits that contain terms and conditions, including all terms required under subdivisions a and c to determine compliance, allowing for the trading of emissions increases and decreases in the permitted facility solely for the purpose of complying with a federally enforceable emissions cap that is established in the permit independent of otherwise applicable requirements provided the changes in emissions are not modifications under title I of the Federal Clean Air Act and the changes do not exceed the emissions allowable under the permit. The permit applicant shall include in

its application proposed replicable procedures and permit terms that ensure the emissions trades are quantifiable and enforceable. The department shall not be required to include in the emissions trading provisions any emissions units for which emissions are not quantifiable or for which there are no replicable procedures to enforce the emissions trades. The permit shall also require compliance with all applicable requirements. The permittee shall supply written notification at least seven days prior to the change to the department and the administrator of the United States environmental protection agency and shall state when the change will occur and shall describe the changes in emissions that will result and how these increases and decreases in emissions will comply with the terms and conditions of the permit. The permit shield described in subdivision f shall extend to terms and conditions that allow such increases and decreases in emissions.

b. Federally enforceable requirements.

(1) All terms and conditions in a title V permit, including any provisions designed to limit a source's potential to emit, are enforceable by the administrator of the United States environmental protection agency and citizens under the Federal Clean Air Act.

(2) Notwithstanding paragraph 1, the department shall specifically designate as not being federally enforceable under the Federal Clean Air Act any terms and conditions included in the permit that are not required under the Federal Clean Air Act or under any of its applicable requirements. Terms and conditions so designated are not subject to the requirements of subsections 6 and 7, or of this subsection, other than those contained in this subdivision.

c. Compliance requirements. All title V permits shall contain the following elements with respect to compliance:

(1) Consistent with paragraph 3 of subdivision a, compliance certification, testing, monitoring, reporting, and recordkeeping requirements sufficient to assure compliance with the terms and conditions of the permit. Any document, including reports, required by a title V permit shall contain a certification by a responsible official that meets the requirements of subdivision d of subsection 4.

(2) Inspection and entry requirements that require that, upon presentation of credentials and other documents as may be

required by law, the permittee shall allow the department or an authorized representative to perform the following:

(a) Enter upon the permittee's premises where a title V source is located or emissions-related activity is conducted, or where records must be kept under the conditions of the permit;

(b) Have access to and copy, at reasonable times, any records that must be kept under the conditions of the permit;

(c) Inspect at reasonable times any facilities, equipment (including monitoring and air pollution control equipment), practices, or operations regulated or required under the permit; and

(d) As authorized by the Federal Clean Air Act and this article, sample or monitor at reasonable times substances or parameters for the purpose of assuring compliance with the permit or applicable requirements.

(3) A schedule of compliance consistent with paragraph 8 of subdivision c of subsection 4.

(4) Progress reports consistent with an applicable schedule of compliance and paragraph 8 of subdivision c of subsection 4 to be submitted at least semiannually, or at a more frequent period if specified in the applicable requirement or by the department. Such progress reports shall contain the following:

(a) Dates for achieving the activities, milestones, or compliance required in the schedule of compliance, and dates when such activities, milestones, or compliance were achieved; and

(b) An explanation of why any dates in the schedule of compliance were not or will not be met, and any preventive or corrective measures adopted.

(5) Requirements for compliance certification with terms and conditions contained in the permit, including emissions limitations, standards, or work practices. Permits shall include each of the following:

(a) The frequency, which is annually or such more frequent periods as specified in the applicable requirement or by the department, of submissions of compliance certifications;

(b) In accordance with paragraph 3 of subdivision a, a means for monitoring the compliance of the source with its emissions limitations, standards, and work practices. The means for monitoring shall be contained in applicable requirements or United States environmental protection agency guidance;

(c) A requirement that the compliance certification include all of the following (provided that the identification of applicable information may cross-reference the permit or previous reports, as applicable):

[1] The identification of each term or condition of the permit that is the basis of the certification;

[2] The identification of the methods or other means used by the owner or operator for determining the compliance status with each term and condition during the certification period. Such methods and other means shall include, at a minimum, the methods and means required under paragraph 3 of subdivision a;

[3] The status of compliance with the terms and conditions of the permit for the period covered by the certification, including whether compliance during the period was continuous or intermittent. The certification shall be based on the method or means designated in item 2. The certification shall identify each deviation and take it into account in the compliance certification. The certification shall also identify as possible exceptions to compliance any periods during which compliance is required and in which an excursion or exceedance as defined under subsection 10 occurred; and

[4] Such other facts as the department may require to determine the compliance status of the source;

(d) A requirement that all compliance certifications be submitted to the administrator of the United States environmental protection agency as well as to the department; and

(e) Such additional requirements as may be specified pursuant to sections 114(a)(3) and 504(b) of the Federal Clean Air Act.

(6) Such other provisions as the department may require.

d. General permits.

(1) The department may, after notice and opportunity for public participation provided under subdivision h of subsection 6, issue a general permit covering numerous similar sources. Any general permit shall comply with all requirements applicable to other title V permits and shall identify criteria by which sources may qualify for the general permit. To sources that qualify, the department shall grant the conditions and terms of the general permit. Notwithstanding the shield provisions of subdivision f, the source shall be subject to enforcement action for operation without a title V permit to operate if the source is later determined not to qualify for the conditions and terms of the general permit. General permits shall not be authorized for affected sources under the acid rain program unless otherwise provided in regulations promulgated under title IV of the Federal Clean Air Act. The department is not required to issue a general permit in lieu of individual title V permits.

(2) Title V sources that would qualify for a general permit must apply to the department for coverage under the terms of the general permit or must apply for a title V permit to operate consistent with subsection 4. The department may, in the general permit, provide for applications which deviate from the requirements of subsection 4, provided that such applications meet the requirements of title V of the Federal Clean Air Act, and include all information necessary to determine qualification for, and to assure compliance with, the general permit. Without repeating the public participation procedures required under subdivision h of subsection 6, the department may grant a source's request for authorization to operate under a general permit, but such a grant shall not be a final permit action for purposes of judicial review.

e. Temporary sources. The department may issue a single permit authorizing emissions from similar operations by the same source owner or operator at multiple temporary locations. The operation must be temporary and involve at least one change of location during the term of the permit. No affected source shall be permitted as a temporary source. Permits for temporary sources shall include the following:

(1) Conditions that will assure compliance with all applicable requirements at all authorized locations;

(2) Requirements that the owner or operator notify the department at least ten days in advance of each change in location; and

(3) Conditions that assure compliance with all other provisions of this section.

f. Permit shield.

(1) Except as provided in this section, upon written request by the applicant, the department shall include in a title V permit to operate a provision stating that compliance with the conditions of the permit shall be deemed compliance with any applicable requirement as of the date of permit issuance, provided that:

(a) Such applicable requirements are included and are specifically identified in the permit; or

(b) The department, in acting on the permit application or revision, determines in writing that other requirements specifically identified are not applicable to the source, and the permit includes the determination or a concise summary thereof.

(2) A title V permit that does not expressly state that a permit shield exists shall be presumed not to provide such a shield.

(3) Nothing in this subdivision or in any title V permit shall alter or affect the following:

(a) The provisions of section 303 of the Federal Clean Air Act (emergency orders), including the authority of the administrator of the United States environmental protection agency under that section;

(b) The liability of an owner or operator of a source for any violation of applicable requirements prior to or at the time of permit issuance;

(c) The applicable requirements of the acid rain program, consistent with section 408(a) of the Federal Clean Air Act; or

(d) The ability of the United States environmental protection agency to obtain information from a source pursuant to section 114 of the Federal Clean Air Act.

g. Emergency provision.

(1) An "emergency" means any situation arising from sudden and reasonably unforeseeable events beyond the control of the source, including acts of God, which situation requires immediate corrective action to restore normal operation, and that causes the source to exceed a technology-based emissions limitation under the title V permit to operate, due to unavoidable increases in emissions attributable to the emergency. An emergency shall not include noncompliance to the extent caused by improperly designed equipment, lack of preventive maintenance, careless or improper operation, or operator error.

(2) Effect of an emergency. An emergency constitutes an affirmative defense to an action brought for noncompliance with such technology-based emissions limitations if the conditions of paragraph 3 are met.

(3) The affirmative defense of emergency shall be demonstrated through properly signed, contemporaneous operating logs, or other relevant evidence that:

(a) An emergency occurred and that the permittee can identify the causes of the emergency;

(b) The permitted facility was at the time being properly operated;

(c) During the period of the emergency the permittee took all reasonable steps to minimize levels of emissions that exceeded the emissions standards, or other requirements in the permit; and

(d) The permittee submitted notice of the emergency to the department within one working day of the time when emissions limitations were exceeded due to the emergency. This notice fulfills the requirement of item 2 of subparagraph c of paragraph 3 of subdivision a. This notice must contain a description of the emergency, any steps taken to mitigate emissions, and corrective actions taken.

(4) In any enforcement proceeding, the permittee seeking to establish the occurrence of an emergency has the burden of proof.

(5) This provision is in addition to any emergency or upset provision contained in any applicable requirement and the malfunction notification required under subdivision b of subsection 2 of section 33-15-01-13 when a threat to health and welfare would exist.

6. **Permit issuance, renewal, reopenings, and revisions.**

a. Action on application.

(1) A permit, permit modification, or permit renewal may be issued only if all of the following conditions have been met:

(a) The department has received a complete application for a permit, permit modification, or permit renewal, except that a complete application need not be received before issuance of a general permit under subdivision d of subsection 5;

(b) Except for modifications qualifying for minor permit modification procedures under paragraphs 1 and 2 of subdivision e, the department has complied with the requirements for public participation under subdivision h;

(c) The department has complied with the requirements for notifying and responding to affected states under subdivision b of subsection 7;

(d) The conditions of the permit provide for compliance with all applicable requirements and the requirements of this section; and

(e) The administrator of the United States environmental protection agency has received a copy of the proposed permit and any notices required under subdivisions a and b of subsection 7, and has not objected to issuance of the permit under subdivision c of subsection 7 within the time period specified therein.

(2) Except for applications received during the initial transitional period described in 40 CFR 70.4(b)(11) or under regulations promulgated under title IV or title V of the Federal Clean Air Act for the permitting of affected sources under the acid rain program, the department shall take final action on each

permit application, including a request for permit modification or renewal, within eighteen months after receiving a complete application.

(3) The department shall provide notice to the applicant of whether the application is complete. Unless the department requests additional information or otherwise notifies the applicant of incompleteness within sixty days of receipt of an application, the application shall be deemed complete. For modifications processed through the minor permit modification procedures, in paragraphs 1 and 2 of subdivision e, a completeness determination is not required.

(4) The department shall provide a statement that sets forth the legal and factual basis for the draft permit conditions, including references to the applicable statutory or regulatory provisions. The department shall send this statement to the United States environmental protection agency and to any other person who requests it.

(5) The submittal of a complete application shall not affect the requirement that any source have a permit to construct under section 33-15-14-02.

b. Requirement for a permit.

(1) Except as provided in the following sentence, paragraphs 2 and 3, subparagraph e of paragraph 1 of subdivision e, and subparagraph e of paragraph 2 of subdivision e, no title V source may operate after the time that it is required to submit a timely and complete application under this section, except in compliance with a permit issued under this section. If a title V source submits a timely and complete application for permit issuance, including for renewal, the source's failure to have a title V permit is not a violation of this section until the department takes final action on the permit application, except as noted in this subsection. This protection shall cease to apply if, subsequent to the completeness determination made pursuant to paragraph 3 of subdivision a, and as required by paragraph 2 of subdivision a of subsection 4, the applicant fails to submit by the deadline specified in writing by the department any additional information identified as being needed to process the application. For timely and complete renewal applications for which the department has failed to issue or deny the renewal permit before the expiration date of the previous permit, all the terms and conditions of the permit, including the permit shield that was granted pursuant

to subdivision f of subsection 5 shall remain in effect until the renewal permit has been issued or denied.

(2) A permit revision is not required for section 502(b)(10) changes provided:

(a) The changes are not modifications under chapters 33-15-12, 33-15-13, and 33-15-15 or title I of the Federal Clean Air Act.

(b) The changes do not exceed the emissions allowable under the title V permit whether expressed therein as a rate of emissions or in terms of total emissions.

(c) A permit to construct under section 33-15-14-02 has been issued, if required.

(d) The facility provides the department and the administrator of the United States environmental protection agency with written notification at least seven days in advance of the proposed change. The written notification shall include a description of each change within the permitted facility, the date on which the change will occur, any change in emissions, and any permit term or condition that is no longer applicable as a result of the change.

The permit shield described in subdivision f of subsection 5 shall not apply to any change made pursuant to this paragraph.

(3) A permit revision is not required for changes that are not addressed or prohibited by the permit provided:

(a) Each such change shall meet all applicable requirements and shall not violate any existing permit term or condition.

(b) The source must provide contemporaneous written notice to the department and the administrator of the United States environmental protection agency of each such change, except for changes that qualify as insignificant under the provisions of subdivision c of subsection 4. Such written notice shall describe each such change, including the date, any change in emissions, contaminants emitted, and any applicable requirement that would apply as a result of the change.

(c) The permittee shall keep a record describing changes made at the source that result in emissions of a regulated air contaminant subject to an applicable requirement, but not otherwise regulated under the permit, and the emissions resulting from those changes.

(d) The changes are not subject to any requirements under title IV of the Federal Clean Air Act.

(e) The changes are not modifications under chapters 33-15-12, 33-15-13, and 33-15-15 or any provision of title I of the Federal Clean Air Act.

(f) A permit to construct under section 33-15-14-02 has been issued, if required.

The permit shield described in subdivision f of subsection 5 shall not apply to any change made pursuant to this paragraph.

c. Permit renewal and expiration.

(1) Permits being renewed are subject to the same procedural requirements, including those for public participation, affected state and the United States environmental protection agency review, that apply to initial permit issuance; and

(2) Permit expiration terminates the source's right to operate unless a timely and complete renewal application has been submitted consistent with subdivision b of subsection 6 and subparagraph c of paragraph 1 of subdivision a of subsection 4.

d. Administrative permit amendments.

(1) An "administrative permit amendment" is a permit revision that:

(a) Corrects typographical errors;

(b) Identifies a change in the name, address, or telephone number of any person identified in the permit, or provides a similar minor administrative change at the source;

(c) Requires more frequent monitoring or reporting by the permittee;

(d) Allows for a change in ownership or operational control of a source if the department determines that no other change in the permit is necessary, provided that a written agreement containing a specific date for transfer of permit responsibility, coverage, and liability between the current and new permittee has been submitted to the department;

(e) Incorporates into the title V permit the requirements from a permit to construct, provided that the permit to construct review procedure is substantially equivalent to the requirements of subsections 6 and 7 that would be applicable to the change if it were subject to review as a permit modification, and compliance requirements substantially equivalent to those contained in subsection 5; or

(f) Incorporates any other type of change which the administrator of the United States environmental protection agency has approved as being an administrative permit amendment as part of the approved title V operating permit program.

(2) Administrative permit amendments for purposes of the acid rain portion of the permit shall be governed by regulations promulgated under title IV of the Federal Clean Air Act.

(3) Administrative permit amendment procedures. An administrative permit amendment may be made by the department consistent with the following:

(a) The department shall take no more than sixty days from receipt of a request for an administrative permit amendment to take final action on such request, and may incorporate such changes without providing notice to the public or affected states provided that it designates any such permit revisions as having been made pursuant to this subdivision.

(b) The department shall submit a copy of the revised permit to the administrator of the United States environmental protection agency.

(c) The source may implement the changes addressed in the request for an administrative amendment immediately upon submittal of the request provided a permit to construct under section 33-15-14-02 has been issued, if required.

(4) The department may, upon taking final action granting a request for an administrative permit amendment, allow coverage by the permit shield in subdivision f of subsection 5 for administrative permit amendments made pursuant to subparagraph e of paragraph 1 of subdivision d which meet the relevant requirements of subsections 5, 6, and 7 for significant permit modifications.

e. Permit modification. A permit modification is any revision to a title V permit that cannot be accomplished under the provisions for administrative permit amendments under subdivision d. A permit modification for purposes of the acid rain portion of the permit shall be governed by regulations promulgated under title IV of the Federal Clean Air Act.

(1) Minor permit modification procedures.

(a) Criteria.

[1] Minor permit modification procedures may be used only for those permit modifications that:

[a] Do not violate any applicable requirement;

[b] Do not involve significant changes to existing monitoring, reporting, or recordkeeping requirements in the permit;

[c] Do not require or change a case-by-case determination of an emissions limitation or other standard, or a source-specific determination for temporary sources of ambient impacts, or a visibility or increment analysis;

[d] Do not seek to establish or change a permit term or condition for which there is no corresponding underlying applicable requirement and that the source has assumed to avoid an applicable requirement to which the source would otherwise be subject. Such terms and conditions include a federally enforceable emissions cap assumed to avoid classification as a modification under any provision of title I of the Federal Clean Air Act; and an alternative emissions limit approved pursuant to regulations

promulgated under section 112(i)(5) of the Federal Clean Air Act;

[e] Are not modifications under chapters 33-15-12, 33-15-13, and 33-15-15 or any provision of title I of the Federal Clean Air Act; and

[f] Are not required to be processed as a significant modification.

[2] Notwithstanding item 1 and subparagraph a of paragraph 2 of subdivision e, minor permit modification procedures may be used for permit modifications involving the use of economic incentives, marketable permits, emissions trading, and other similar approaches, to the extent that such minor permit modification procedures are explicitly provided for in the state implementation plan, or in applicable requirements promulgated by the United States environmental protection agency.

(b) Application. An application requesting the use of minor permit modification procedures shall meet the requirements of subdivision c of subsection 4 and shall include the following:

[1] A description of the change, the emissions resulting from the change, and any new applicable requirements that will apply if the change occurs;

[2] The source's suggested draft permit;

[3] Certification by a responsible official, consistent with subdivision d of subsection 4, that the proposed modification meets the criteria for use of minor permit modification procedures and a request that such procedures be used; and

[4] Completed forms for the department to use to notify the administrator of the United States environmental protection agency and affected states as required under subsection 7.

(c) United States environmental protection agency and affected state notification. Within five working days of receipt of a complete permit modification application, the department shall notify the administrator of the United States environmental protection agency and affected states of the requested permit modification. The department shall promptly send any notice required under paragraph 2 of subdivision b of subsection 7 to the administrator of the United States environmental protection agency.

(d) Timetable for issuance. The department may not issue a final permit modification until after the United States environmental protection agency forty-five-day review period or until the United States environmental protection agency has notified the department that the United States environmental protection agency will not object to issuance of the permit modification, whichever is first, although the department can approve the permit modification prior to that time. Within ninety days of the department's receipt of an application under minor permit modification procedures or fifteen days after the end of the administrator's forty-five-day review period under subdivision c of subsection 7, whichever is later, the department shall:

[1] Issue the permit modification as proposed;

[2] Deny the permit modification application;

[3] Determine that the requested modification does not meet the minor permit modification criteria and should be reviewed under the significant modification procedures; or

[4] Revise the draft permit modification and transmit to the administrator the new proposed permit modification as required by subdivision a of subsection 7.

(e) Source's ability to make change. A source may make the change proposed in its minor permit modification application only after it files such application and the department approves the change in writing. If the department allows the source to make the proposed change prior to taking action specified in items 1, 2, and 3 of subparagraph d, the source must comply with both the applicable requirements governing the change and the proposed permit terms and conditions. During this time period, the source need not comply with the existing permit terms and conditions it seeks to modify. However, if the source fails to comply with its proposed permit terms and conditions during this time period, the existing permit terms and conditions it seeks to modify may be enforced against it.

(f) The permit shield under subdivision f of subsection 5 shall not extend to minor permit modifications.

(2) Group processing of minor permit modifications. Consistent with this paragraph, the department may modify the procedure outlined in paragraph 1 to process groups of a source's applications for certain modifications eligible for minor permit modification processing.

(a) Criteria. Group processing of modifications may be used only for those permit modifications:

[1] That meet the criteria for minor permit modification procedures under item 1 of subparagraph a of paragraph 1 of subdivision e; and

[2] That collectively are below the threshold level which is ten percent of the emissions allowed by the permit for the emissions unit for which the change is requested, twenty percent of the applicable definition of major source in subsection 1, or five tons [4.54 metric tons] per year, whichever is least.

(b) Application. An application requesting the use of group processing procedures shall meet the requirements of subdivision c of subsection 4 and shall include the following:

[1] A description of the change, the emissions resulting from the change, and any new applicable requirements that will apply if the change occurs.

[2] The source's suggested draft permit.

[3] Certification by a responsible official, consistent with subdivision d of subsection 4, that the proposed modification meets the criteria for use of group processing procedures and a request that such procedures be used.

[4] A list of the source's other pending applications awaiting group processing, and a determination of

whether the requested modification, aggregated with these other applications, equals or exceeds the threshold set under item 2 of subparagraph a of paragraph 2 of subdivision e.

[5] Certification, consistent with subdivision d of subsection 4, that the source has notified the United States environmental protection agency of the proposed modification. Such notification need only contain a brief description of the requested modification.

[6] Completed forms for the department to use to notify the administrator of the United States environmental protection agency and affected states as required under subsection 7.

(c) United States environmental protection agency and affected state notification. On a quarterly basis or within five business days of receipt of an application demonstrating that the aggregate of a source's pending applications equals or exceeds the threshold level set under item 2 of subparagraph a of paragraph 2 of subdivision e, whichever is earlier, the department shall meet its obligation under paragraph 1 of subdivision a of subsection 7 and paragraph 1 of subdivision b of subsection 7 to notify the administrator of the United States environmental protection agency and affected states of the requested permit modifications. The department shall send any notice required under paragraph 2 of subdivision b of subsection 7 to the administrator of the United States environmental protection agency.

(d) Timetable for issuance. The provisions of subparagraph d of paragraph 1 of subdivision e shall apply to modifications eligible for group processing, except that the department shall take one of the actions specified in items 1 through 4 of subparagraph d of paragraph 1 of subdivision e within one hundred eighty days of receipt of the application or fifteen days after the end of the administrator's forty-five-day review period under subdivision c of subsection 7, whichever is later.

(e) Source's ability to make change. The provisions of subparagraph e of paragraph 1 apply to modifications eligible for group processing.

(f) The permit shield under subdivision f of subsection 5 shall not extend to group processing of minor permit modifications.

(3) Significant modification procedures.

(a) Criteria. Significant modification procedures shall be used for applications requesting permit modifications that do not qualify as minor permit modifications or as administrative amendments. Every significant change in existing monitoring permit terms or conditions and every relaxation of reporting or recordkeeping permit terms or conditions shall be considered significant. Nothing herein shall be construed to preclude the permittee from making changes consistent with this subsection that would render existing permit compliance terms and conditions irrelevant.

(b) Significant permit modifications shall meet all requirements of this section, including those for applications, public participation, review by affected states, and review by the United States environmental protection agency, as they apply to permit issuance and permit renewal. The department shall complete review of significant permit modifications within nine months after receipt of a complete application.

f. Reopening for cause.

(1) Each issued permit shall include provisions specifying the conditions under which the permit will be reopened prior to the expiration of the permit. A permit shall be reopened and revised under any of the following circumstances:

(a) Additional applicable requirements under the Federal Clean Air Act become applicable to a major title V source with a remaining permit term of three or more years. Such a reopening shall be completed not later than eighteen months after promulgation of the applicable requirement. No such reopening is required if the effective date of the requirement is later than the date on which the permit is due to expire, unless the original permit or any of its terms and conditions has been extended.

(b) Additional requirements, including excess emissions requirements, become applicable to an affected source under title IV of the Federal Clean Air Act or the regulations promulgated thereunder. Upon approval by the administrator of the United States environmental protection agency, excess emissions offset plans shall be deemed to be incorporated into the permit.

(c) The department or the United States environmental protection agency determines that the permit contains a material mistake or that inaccurate statements were made in establishing the emissions standards or other terms or conditions of the permit.

(d) The administrator of the United States environmental protection agency or the department determines that the permit must be revised or revoked to assure compliance with the applicable requirements.

(2) Proceedings to reopen and issue a permit shall follow the same procedures as apply to initial permit issuance and shall affect only those parts of the permit for which cause to reopen exists. Such reopening shall be made as expeditiously as practicable.

(3) Reopenings under paragraph 1 shall not be initiated before a notice of such intent is provided to the title V source by the department at least thirty days in advance of the date that the permit is to be reopened, except that the department may provide a shorter time period in the case of an emergency.

g. Reopenings for cause by the United States environmental protection agency.

(1) If the administrator of the United States environmental protection agency finds that cause exists to terminate, modify, or revoke and reissue a permit pursuant to subdivision f, within ninety days after receipt of such notification, the department shall forward to the United States environmental protection agency a proposed determination of termination, modification, or revocation and reissuance, as appropriate.

(2) The administrator of the United States environmental protection agency will review the proposed determination from the department within ninety days of receipt.

(3) The department shall have ninety days from receipt of the United States environmental protection agency objection to resolve any objection that the United States environmental protection agency makes and to terminate, modify, or revoke and reissue the permit in accordance with the administrator's objection.

(4) If the department fails to submit a proposed determination or fails to resolve any objection, the administrator of the United States environmental protection agency will terminate, modify, or revoke and reissue the permit after taking the following actions:

  (a) Providing at least thirty days' notice to the permittee in writing of the reasons for any such action.

  (b) Providing the permittee an opportunity for comment on the administrator's proposed action and an opportunity for a hearing.

h. Public participation. Except for modifications qualifying for minor permit modification procedures, all permit proceedings, including initial permit issuance, significant modifications, and renewals, shall be subject to procedures for public notice including offering an opportunity for public comment and a hearing on the draft permit. These procedures shall include the following:

(1) Notice shall be given by publication in a newspaper of general circulation in the area where the source is located or in a state publication designed to give general public notice; to persons on a mailing list developed by the department, including those who request in writing to be on the list; and by other means if necessary to assure adequate notice to the affected public;

(2) The notice shall identify the affected facility; the name and address of the permittee; the name and address of the department; the activity or activities involved in the permit action; the emissions change involved in any permit modification; the name, address, and telephone number of a person from whom interested persons may obtain additional information, including copies of the permit draft, the application, all relevant supporting materials, and all other materials available to the department that are relevant to the permit decision; a brief description of the comment procedures required by this subsection; and the time and place of any hearing that may be held, including a statement of procedures to request a hearing, unless a hearing has already been scheduled;

(3) The department shall provide such notice and opportunity for participation by affected states as is provided for by subsection 7;

(4) The department shall provide at least thirty days for public comment and shall give notice of any public hearing at least thirty days in advance of the hearing; and

(5) The department shall keep a record of the commenters and also of the issues raised during the public participation process. These records shall be available to the public.

7. **Permit review by the United States environmental protection agency and affected states.**

a. Transmission of information to the administrator.

(1) The department shall provide a copy of each permit application including any application for a permit modification (including the compliance plan), to the administrator of the United States environmental protection agency except that the applicant shall provide such information directly to the administrator of the United States environmental protection agency when directed to do so by the department. The department shall provide a copy of each proposed permit and each final title V permit to operate to the administrator of the United States environmental protection agency. To the extent practicable, the preceding information shall be provided in computer-readable format compatible with the United States environmental protection agency's national data base management system.

(2) The department may waive the requirements of paragraph 1 and paragraph 1 of subdivision b for any category of sources (including any class, type, or size within such category) other than major sources upon approval by the administrator of the United States environmental protection agency.

(3) The department shall keep these records for at least five years.

b. Review by affected states.

(1) The department shall give notice of each draft permit to any affected state on or before the time that the notice to the public under subdivision h of subsection 6 is given, except to the extent paragraphs 1 and 2 of subdivision e of subsection 6 require the timing of the notice to be different.

(2) As part of the submittal of the proposed permit to the administrator of the United States environmental protection agency (or as soon as possible after the submittal for minor permit modification procedures allowed under paragraphs 1 and 2 of subdivision e of subsection 6) the department shall notify the administrator of the United States environmental protection agency and any affected state in writing of any refusal by the department to accept all recommendations

for the proposed permit that the affected state submitted during the public or affected state review period. The notice shall include the department's reasons for not accepting any such recommendation. The department is not required to accept recommendations that are not based on applicable requirements or the requirements of this section.

c. United States environmental protection agency objection. No permit for which an application must be transmitted to the administrator of the United States environmental protection agency under subdivision a shall be issued if the administrator of the United States environmental protection agency objects to its issuance in writing within forty-five days of receipt of the proposed permit and all necessary supporting information.

d. Public petitions to the administrator of the United States environmental protection agency. If the administrator of the United States environmental protection agency does not object in writing under subdivision c, any person may petition the administrator of the United States environmental protection agency within sixty days after the expiration of the administrator's forty-five-day review period to make such objection. Any such petition shall be based only on objections to the permit that were raised with reasonable specificity during the public comment period provided for in subdivision h of subsection 6, unless the petitioner demonstrates that it was impracticable to raise such objections within such period, or unless the grounds for such objection arose after such period. If the administrator of the United States environmental protection agency objects to the permit as a result of a petition filed under this subdivision, the department shall not issue the permit until the United States environmental protection agency's objection has been resolved, except that a petition for review does not stay the effectiveness of a permit or its requirements if the permit was issued after the end of the forty-five-day review period and prior to the United States environmental protection agency's objection. If the department has issued a permit prior to receipt of the United States environmental protection agency's objection under this subdivision, the department may thereafter issue only a revised permit that satisfies the United States environmental protection agency's objection. In any case, the source will not be in violation of the requirement to have submitted a timely and complete application.

e. Prohibition on default issuance. The department shall issue no title V permit to operate, including a permit renewal or modification, until affected states and the United States environmental protection agency have had an opportunity to review the proposed permit as required under this subsection.

8. **Judicial review of title V permit to operate decisions.**

   a. The applicant, any person who participated in the department's public participation process, and any other person who could obtain judicial review under North Dakota Century Code section 28-32-42 may obtain judicial review provided such appeal is filed in accordance with North Dakota Century Code section 28-32-42 within thirty days after notice of the final permit action.

   b. The department's failure to take final action on an application for a permit, permit renewal, or permit revision within the timeframes referenced in this section shall be appealable in accordance with North Dakota Century Code section 28-32-42 within thirty days after expiration of the applicable timeframes.

   c. In accordance with North Dakota Century Code chapter 28-32, the mechanisms outlined in this subsection shall be the exclusive means for judicial review of permit decisions referenced in this section.

   d. Solely for the purpose of obtaining judicial review in state court, final permit action shall include the failure of the department to take final action on an application for a permit, permit renewal, or permit revision within the timeframes referenced in this section.

   e. Failure to take final action within ninety days of receipt of an application requesting minor permit modification procedures (or one hundred eighty days for modifications subject to group processing requirements) shall be considered final action and subject to judicial review in state court.

9. **Enforcement.** The department may suspend, revoke, or terminate a permit for violations of this article, violation of any permit condition or for failure to respond to a notice of violation or any order issued pursuant to this article. A permit to operate which has been revoked or terminated pursuant to this article must be surrendered forthwith to the department. No person may operate or cause the operation of a source if the department denies, terminates, revokes, or suspends a permit to operate.

10. **Compliance assurance monitoring.** Except as noted below, title 40, Code of Federal Regulations, part 64 compliance assurance monitoring, as it exists on January 31, 2004, is incorporated by reference.

    a. "Administrator" means the department except for those duties that cannot be delegated by the United States environmental protection agency. For those duties that cannot be delegated, administrator means the department and the administrator of the United States environmental protection agency.

b. "Part 70 permit" means a title V permit to operate.

c. "Permitting authority" means the department.

History: Effective March 1, 1994; amended effective December 1, 1994; August 1, 1995; January 1, 1996; September 1, 1997; September 1, 1998; March 1, 2003; February 1, 2005.
General Authority: NDCC 23-25-03, 23-25-04, 23-25-04.1
Law Implemented: NDCC 23-25-03, 23-25-04, 23-25-04.1, 23-25-10

33-15-14-07. Source exclusions from title V permit to operate requirements.

1. **Purpose.** The purpose of this section is to clarify which sources are minor sources with respect to section 33-15-14-06. The owner or operator of any source that would be classified as a major source under section 33-15-14-06 and which is not specifically excluded by this section shall comply with the requirements of section 33-15-14-06.

2. **Definitions.** For purposes of this section:

   a. "Bulk gasoline plant" means any bulk gasoline distribution facility that has a gasoline throughput less than or equal to twenty thousand gallons [75700 liters] per day and that receives gasoline by truck rather than by rail.

   b. "Coatings" means coatings plus diluents plus cleanup solvents.

   c. "Fountain solution additives" includes isopropyl alcohol, n-propyl alcohol, n-butanol, and alcohol substitutes.

   d. "Hazardous air contaminant" means any air contaminant listed pursuant to subsection 112(b) of the Federal Clean Air Act.

   e. "Refueling positions" means the number of vehicles that could be dispensing simultaneously at a gasoline service station.

3. **Applicability.**

   a. The owner or operator of the following stationary sources is not required to obtain a title V permit to operate under section 33-15-14-06 if the conditions of this section are met:

      (1) Gasoline service stations.

      (2) Gasoline bulk plants.

      (3) Coating sources.

    (4) Printing, publishing, and packaging operations.

    (5) Degreasers using volatile organic solvents.

    (6) Hot mix asphalt plants.

b. Any facility obtaining coverage under this section must submit a notification in writing to the department within ninety days of publication of this section unless specifically exempted from this requirement in the applicable subdivision of this section. The notification must contain the following information:

    (1) Facility name, location, and nature of business.

    (2) A list of all the sources of air contaminants at the facility.

    (3) The condition of this section which is applicable to the facility.

    (4) Total material usage, source capacity, or throughput for the previous month or twelve months at the facility, in accordance with the subdivision that is applicable to the facility.

    (5) A signed statement accepting the throughput or usage limitation.

c. Complying with the conditions of this section does not exempt the owner or operator of a facility from the obligation to apply for and obtain a permit to construct or a minor source permit to operate unless specifically exempted in section 33-15-14-02 or 33-15-14-03.

d. The owner or operator of any facility listed in subdivision a which has potential emissions that would classify it as a major source even after the conditions of this section are met, or are not able to comply with the applicable conditions, shall obtain a title V permit to operate or a minor source permit to operate which limits the potential to emit of the source to a level below the major source threshold.

e. Complying with the conditions of this section does not relieve the owner or operator of a source of the responsibility to comply with any other applicable requirements of this article.

f. If the facility deviates from any condition, limit, or requirement of this section, a report must be submitted to the department within thirty days of the deviation containing the following information:

    (1) The facility's name and location.

(2) Applicable condition, limit, or requirement for the facility for which a deviation occurred.

(3) A summary of the records showing the deviation, accompanied by an explanation of the deviation.

(4) A plan of action to prevent future occurrences of any deviation at the facility.

g. All records required by this section must be maintained for a period of five years from the last date of entry. The records must be available for inspection or submittal to the department upon request. If a facility is limited by a material usage, capacity, or throughput based on a twelve-month rolling period, a log must be updated monthly to include the previous twelve months' total material usage, capacity, or throughput.

4. **Exclusion standards.**

a. Gasoline service stations. The owner or operator of sources where gasoline dispensing operations account for more than ninety percent of all emissions from the facility is not required to obtain a title V permit to operate if the following conditions are met:

(1) No vapor recovery is used:

(a) The source's total sales of gasoline must not exceed three hundred eighty thousand gallons [1438300 liters] per month in any calendar month. To demonstrate compliance with this limit, monthly records of throughput must be maintained at the source.

(b) If the number of refueling positions is no more than seventeen at the source, then the source is exempt from formal application to the department under subdivision b of subsection 3.

(2) Stage I vapor recovery is used:

(a) The source's total sales of gasoline must not exceed six hundred thirty thousand gallons [2384800 liters] per month in any calendar year. To demonstrate compliance with this limit, monthly records of throughput must be maintained at the source.

(b) If the number of refueling positions is no more than twenty-nine at the source, then the source is exempt from formal application to the department under subdivision b of subsection 3.

b. Gasoline bulk plants. The owner or operator of gasoline bulk plants where gasoline loading and unloading operations account for more than ninety percent of all emissions from the source are covered by this subdivision. To demonstrate compliance with the twenty thousand gallons [75700 liters] per day of gasoline definition of a bulk plant, monthly records of throughput must be maintained at the source.

c. Coating sources.

  (1) The owner or operator of sources where surface coating operations account for more than ninety percent of all hazardous air contaminant emissions from the facility is not required to obtain a title V permit to operate if the conditions in subparagraph a or b are met.

    (a) The source's total usage of surface coatings must not exceed two hundred fifty gallons [946.25 liters] of coatings per month in any calendar month nor exceed three thousand gallons [11355 liters] of coatings per twelve-month period. The coatings are limited to six pounds per gallon [719 grams per liter] of any individual hazardous air contaminant. To demonstrate compliance with the usage limit, monthly records of material usage must be maintained at the facility.

    (b) The source's total hazardous air contaminant emissions shall not exceed ten tons per twelve-month period. Hazardous air contaminant emissions must be calculated by multiplying the surface coating material usage in gallons by the individual hazardous air contaminant content in pounds per gallon. To demonstrate compliance with the emissions limitation, the emissions must be calculated on a monthly basis and recorded in a log. All records of material usage, hazardous air contaminant content, and emissions must be maintained at the facility.

  (2) The owner or operator of an automobile refinishing shop where operations account for more than ninety percent of volatile organic compound emissions and hazardous air contaminant emissions is not required to obtain a title V permit to operate if the usage of coatings is less than two hundred fifty gallons [946.25 liters] per month or three thousand gallons [11355 liters] of coatings per twelve-month period. This item does not apply to facilities capable of refinishing vehicles other than automobiles or trucks. Sources are exempt from the notification requirements under subdivision b of subsection 3 if:

(a) The auto refinishing shop business is entirely, or almost entirely, for collision repairs and the business has two or fewer bays;

(b) Substantial portions of the auto refinishing shop business are devoted to repainting entire vehicles and the business only has one bay devoted to painting; or

(c) The auto refinishing shop business does not have the physical or operational capability to do more than fifty jobs per week.

d. Printing, publishing, and packaging operations.

(1) The owner or operator of facilities where sheetfed (nonheatset) offset lithography or nonheatset web offset lithography printing operations are conducted is not required to obtain a title V permit to operate if the conditions in subparagraphs a, b, and c are met.

(a) The facility must use less than fourteen thousand two hundred seventy-five gallons [54030 liters] of cleaning solvent and fountain solution additives in any twelve-month rolling period. To demonstrate compliance with the usage limit, monthly records of material usage must be maintained at the facility.

(b) The facility must use less than three thousand three hundred thirty-three gallons [12615 liters] of materials containing multiple hazardous air contaminants in any twelve-month rolling period. To demonstrate compliance with the usage limit, monthly records of material usage must be maintained at the facility.

(c) The facility must use less than one thousand three hundred thirty-three gallons [5045 liters] of material containing any individual hazardous air contaminant in any twelve-month rolling period. To demonstrate compliance with the usage limit, monthly records of material usage must be maintained at the facility.

(2) The owner or operator of facilities where heatset web offset lithography printing operations are conducted is not required to obtain a title V permit to operate if the conditions in subparagraphs a, b, and c are met.

(a) The facility must use less than one hundred thousand pounds [45.36 megagrams] of ink, cleaning solvent, and fountain solution additives in any twelve-month rolling period. To demonstrate compliance with the usage limit, monthly records of material usage must be maintained at the facility.

(b) The facility must use less than three thousand three hundred thirty-three gallons [12615 liters] of materials containing multiple hazardous air contaminants in any twelve-month rolling period. To demonstrate compliance with the usage limit, monthly records of material usage must be maintained at the facility.

(c) The facility must use less than one thousand three hundred thirty-three gallons [5045 liters] of material containing any individual hazardous air contaminant in any twelve-month rolling period. To demonstrate compliance with the usage limit, monthly records of material usage must be maintained at the facility.

(3) The owner or operator of facilities where screen printing operations are conducted is not required to obtain a title V permit to operate if the conditions in subparagraphs a, b, and c are met.

(a) The facility must use less than fourteen thousand two hundred seventy-five gallons [54030 liters] of the sum of solvent-based inks, cleaning solvents, adhesives, and coatings in any twelve-month rolling period. To demonstrate compliance with the usage limit, monthly records of material usage must be maintained at the facility.

(b) The facility must use less than three thousand three hundred thirty-three gallons [12615 liters] of materials containing multiple hazardous air contaminants in any twelve-month rolling period. To demonstrate compliance with the usage limit, monthly records of material usage must be maintained at the facility.

(c) The facility must use less than one thousand three hundred thirty-three gallons [5045 liters] of material containing any individual hazardous air contaminant in any twelve-month rolling period. To demonstrate compliance with the usage limit, monthly records of material usage must be maintained at the facility.

(4) The owner or operator of facilities, where flexography, or rotogravure printing operations with water-based or ultraviolet-cured inks, coatings, and adhesives are

conducted, is not required to obtain a title V permit to operate if the conditions in subparagraphs a, b, and c are met.

(a) The facility must use less than four hundred thousand pounds [181 megagrams] of the sum of solvent-based inks, cleaning solvents, and adhesives in any twelve-month rolling period. To demonstrate compliance with the usage limit, monthly records of material usage must be maintained at the facility.

(b) The facility must use less than three thousand three hundred thirty-three gallons [12615 liters] of materials containing multiple hazardous air contaminants in any twelve-month rolling period. To demonstrate compliance with the usage limit, monthly records of material usage must be maintained at the facility.

(c) The facility must use less than one thousand three hundred thirty-three gallons [5045 liters] of material containing any individual hazardous air contaminant in any twelve-month rolling period. To demonstrate compliance with the usage limit, monthly records of material usage must be maintained at the facility.

(5) The owner or operator of facilities where flexography or rotogravure printing operations with solvent inks are conducted is not required to obtain a title V permit to operate if the conditions in subparagraphs a, b, and c are met.

(a) The facility must use less than one hundred thousand pounds [45.36 megagrams] of the sum of ink, coatings, adhesives, dilution solvents, and cleaning solvents in any twelve-month rolling period. To demonstrate compliance with the usage limit, monthly records of material usage must be maintained at the facility.

(b) The facility must use less than three thousand three hundred thirty-three gallons [12615 liters] of materials containing multiple hazardous air contaminants in any twelve-month rolling period. To demonstrate compliance with the usage limit, monthly records of material usage must be maintained at the facility.

(c) The facility must use less than one thousand three hundred thirty-three gallons [5045 liters] of material containing any individual hazardous air contaminant in any twelve-month rolling period. To demonstrate compliance with the usage limit, monthly records of material usage must be maintained at the facility.

e. Degreasers using volatile organic solvents. The owner or operator of facilities where degreasing operations account for more than ninety percent of all volatile organic compound emissions and hazardous air contaminant emissions from the facility is not required to obtain a title V permit to operate if the conditions in paragraph 1 or 2 are met.

   (1) If non-halogenated solvents are used, the usage is limited to two thousand two hundred gallons [8327 liters] of any one solvent-containing material and five thousand four hundred gallons [20439 liters] of any combination of solvent-containing materials in any twelve-month rolling period. To demonstrate compliance with the usage limit, monthly records of solvent usage must be maintained at the facility.

   (2) If halogenated solvents are used, including methyl chloroform, trichloroethane, and methylene chloride, the usage is limited to one thousand two hundred gallons [4542 liters] of any one solvent-containing material and two thousand nine hundred gallons [10976 liters] of any combination of solvent-containing materials in any twelve-month rolling period. To demonstrate compliance with the usage limit, monthly records of solvent usage must be maintained at the facility.

f. Hot mix asphalt plants. The owner or operator of facilities where hot mix asphalt production operations account for more than ninety percent of all emissions from the facility is not required to obtain a title V permit to operate if the amount of hot mix asphalt produced does not exceed two hundred fifty thousand tons [226757 metric tons] in any twelve-month rolling period. To demonstrate compliance with this limit, monthly records of hot mix asphalt produced must be maintained at the facility. Sources that are excluded under this subdivision must obtain a minor source permit to operate under section 33-15-14-03.

CHAPTER 33-15-25
REGIONAL HAZE REQUIREMENTS

Section

33-15-25-01 Definitions
33-15-25-02 Best Available Retrofit Technology
33-15-25-03 Guidelines for Best Available Retrofit Technology Determinations Under the Regional Haze Rule
33-15-25-04 Monitoring, Recordkeeping, and Reporting

33-15-25-01. Definitions. The definitions in title 40, Code of Federal Regulations, part 51, section 301, as they exist on October 1, 2005, are incorporated by reference into this chapter. For purposes of this chapter only:

1. "Boiler operating day" means any twenty-four-hour period between midnight and the following midnight during which any fuel is combusted at any time at the steam generating unit.

2. "Contributes to visibility impairment" means a change in visibility impairment in a class I federal area of five-tenths deciviews or more (twenty-four-hour average) above the average natural visibility baseline. A source exceeds the threshold when the ninety-eighth percentile (eighth highest value) of the modeling results based on any one year of the three years of meteorological data modeled exceeds five-tenths deciviews.

History: Effective January 1, 2007.
General Authority: NDCC 23-25-03, 23-25-04
Law Implemented: NDCC 23-25-03, 23-25-04

33-15-25-02. Best available retrofit technology.

1. **Submission of best available retrofit technology analysis.** The owner or operator of any existing stationary facility as defined in title 40, Code of Federal Regulations, part 51, section 301, that contributes to visibility impairment in a class I federal area shall submit a best available retrofit technology analysis to the department. The analysis shall be submitted within nine months after being notified by the department that the existing stationary facility contributes to visibility impairment.

2. **Installation of best available retrofit technology.** The owner or operator of any existing stationary facility as defined in title 40, Code of Federal Regulations, section 301, which contributes to visibility impairment in a class I federal area shall install and operate best available retrofit technology. The equipment shall be installed and operating as expeditiously as practicable but in no event later than five years after the United States environmental protection agency's

approval of North Dakota's state implementation plan revision for best available retrofit technology.

3. **Operation and maintenance of best available retrofit technology.** The owner or operator of a facility required to install best available retrofit technology under subsection 1 shall establish procedures to ensure such equipment is properly operated and maintained.

History: Effective January 1, 2007.
General Authority: NDCC 23-25-03, 23-25-04
Law Implemented: NDCC 23-25-03, 23-25-04

33-15-25-03. Guidelines for best available retrofit technology determinations under the regional haze rule. Title 40, Code of Federal Regulations, part 51, appendix y, as published in the federal register on July 6, 2005, is incorporated by reference into this chapter.

The owner or operator of a fossil-fuel-fired steam electric plant with a generating capacity greater than seven hundred fifty megawatts of electricity shall comply with the requirements of appendix y. All other facility owners or operators shall use appendix y as guidance for preparing their best available control retrofit technology determinations.

History: Effective January 1, 2007.
General Authority: NDCC 23-25-03, 23-25-04
Law Implemented: NDCC 23-25-03, 23-25-04

33-15-25-04. Monitoring, recordkeeping, and reporting. The owner or operator of any existing stationary facility that is required to install best available retrofit technology shall conduct monitoring, recordkeeping, and reporting sufficient to show compliance or noncompliance. Monitoring for sulfur dioxide and nitrogen oxides from the main stack of a fossil-fuel-fired steam electric plant shall be conducted using continuous emissions monitoring systems which comply with the requirements of section 33-15-21-09. Particulate monitoring shall be in accordance with the requirements of subsection 10 of section 33-15-14-06. Recordkeeping and reporting shall comply with the requirements of section 33-15-14-06. Monitoring, recordkeeping, and reporting for other source units shall comply with the requirements of section 33-15-14-06.

History: Effective January 1, 2007.

Supplementary Information for Four-Factor Analyses for Selected Individual Facilities in North Dakota

May 18, 2009

Revised Draft Report

Prepared by:

Brad Nelson
William Battye
Janet Hou

EC/R Incorporated
501 Eastowne Drive, Suite 250
Chapel Hill, North Carolina 27514

Prepared for:

Lee Gribovicz, Project Manager

Western Regional Air Partnership (WRAP) and
Western Governors' Association (WGA)
1600 Broadway, Suite 1700
Denver, Colorado 80202

Scope of Document

This document provides an initial analysis of the four factors which must be considered in establishing a reasonable progress goal toward achieving natural visibility conditions in mandatory Class I areas. These factors were examined for several candidate control measures for priority pollutants and emission sources. The results of this report are intended to inform policymakers in setting reasonable progress goals for the Class I areas in the Western Regional Air Partnership (WRAP) region.

This document does not address policy issues, set reasonable progress goals, or recommend a long-term strategy for regional haze. Separate documents will be prepared by the States which address the reasonable progress goals, each state's share of emission reductions, and coordinated emission control strategies.

Disclaimer

The analysis described in this document has been funded by the Western Governors' Association. It has been subject to review by the WGA and the WRAP. However, the report does not necessarily reflect the views of the sponsoring and participating organizations, and no official endorsement should be inferred.

scfm	Standard Cubic Feet per Minute

1. Introduction

The Regional Haze Rule requires States to set reasonable progress goals toward meeting a national goal of natural visibility conditions in Class I areas by the year 2064. The first reasonable progress goals will be established for the planning period 2008 to 2018. The Western Regional Air Partnership (WRAP), along with its member states, tribal governments, and federal agencies, are working to address visibility impairment due to regional haze in Class I areas. The Regional Haze Rule identifies four factors which should be considered in evaluating potential emission control measures to meet visibility goals. These are as follows:

1. Cost of compliance
2. Time necessary for compliance
3. Energy and non-air quality environmental impacts of compliance
4. Remaining useful life of any existing source subject to such requirements

This report has been prepared as part of a project to evaluate the above factors for possible control strategies intended to improve visibility in the WRAP region. We have identified control measures for emissions of nitrogen oxides (NO_X) and sulfur dioxide (SO_2), which can react in the atmosphere to produce visibility-obscuring particulate matter on a regional scale, and also for direct emissions of particulate matter. For direct particulate matter emissions (PM), we have evaluated the impacts of control measures on various particulate matter components, including $PM_{2.5}$, PM_{10}, elemental carbon (EC) particulate matter, and organic carbon (OC) particulate matter. A number of emission source categories have been addressed, including:

1. Reciprocating internal combustion engines and turbines
2. Oil and natural gas exploration and production field operations
3. Natural gas processing plants
4. Industrial boilers
5. Cement manufacturing plants
6. Sulfuric acid manufacturing plants
7. Pulp and paper plant lime kilns
8. Petroleum refinery process heaters

The four-factor analyses for these emission categories are documented in a separate report, entitled “Assessing Reasonable Progress for Regional Haze in the WRAP Region – Source Category Analysis.”

The current report presents the results of a four-factor analysis of potential control measures for selected emission sources in North Dakota. The emission sources addressed in this current report were selected by the North Dakota Department of Health, and include two electric generating units, three industrial boilers at a coal gasification facility, a sulfur recovery unit and several compressor engines at a natural gas processing facility, and a sulfur recovery unit at another gas processing facility. This report is organized in 4 sections, including this introduction. Section 2 presents the methodology employed to conduct the following analyses and Section 3 results of the four-factor analysis for boilers, including the electric generating units and the industrial boiler at the coal gasification facility. Section 4 gives the results of the four-factor analysis for the natural gas processing facilities.

2. Methodology

The first step in the technical evaluation of control measures for a source category was to identify the major sources of emissions from the category. Emissions assessments were initially based on 2002 emissions inventory in the WRAP Emissions Data Management System (EDMS),[1] which consists of data submitted by the WRAP states in 2004. The states then reviewed the emissions data and parameters from the EDMS used for this analysis and provided updated data when applicable. In some cases, detailed data on PM_{10} and $PM_{2.5}$ emissions were not available from the WRAP inventory. Therefore, PM_{10} and $PM_{2.5}$ data from the U.S. Environmental Protection Agency's (EPA) 2002 National Emissions Inventory (NEI) were used to supplement the WRAP inventory where necessary.

Once the important emission sources were identified within a given emission source category, a list of potential additional control technologies was compiled from a variety of sources, including control techniques guidelines published by the EPA, emission control cost models such as AirControlNET[2] and CUECost,[3] Best Available Retrofit Technology (BART) analyses, White Papers prepared by the Midwest Regional Planning Organization (MRPO),[4] and a menu of control options developed by the National Association of Clean Air Agencies (NACAA).[5] The options for each source category were then narrowed to a set of technologies that would achieve the emission reduction target under consideration. The following sections discuss the methodology used to analyze each of the regional haze factors for the selected technologies.

2.1 Factor 1 – Costs

Control costs include both the capital costs associated with the purchase and installation of retrofit and new control systems, and the net annual costs (which are the annual reoccurring costs) associated with system operation. The basic components of total capital costs are direct capital costs, which includes purchased equipment and installation costs, and indirect capital expenses. Direct capital costs consist of such items as purchased equipment cost, instrumentation and process controls, ductwork and piping, electrical components, and structural and foundation costs. Labor costs associated with construction and installation are also included in this category. Indirect capital expenses are comprised of engineering and design costs, contractor fees, supervisory expenses, and startup and performance testing. Contingency costs, which represent such costs as construction delays, increased labor and equipment costs, and design modification, are an additional component of indirect capital expenses. Capital costs also include the cost of process modifications. Annual costs include amortized costs of capital investment, as well as costs of operating labor, utilities, and waste disposal. For fuel switching options, annual costs include the cost differential between the current fuel and the alternate fuel.

The U.S. EPA's *Guidance for Setting Reasonable Progress Goals under the Regional Haze Program*[6] indicates that the four-factor analyses should conform to the methodologies given in the *EPA Air Pollution Control Cost Manual*.[7] This study draws on cost analyses which have followed the protocols set forth in the Cost Manual. Where possible, we have used the primary references for cost data. Cost estimates have been updated to 2007 dollars using the Marshall & Swift Equipment Cost Index or the Chemical Engineering Plant Cost Index, both of which are published in the journal, *Chemical Engineering.*

For Factor 1, results of the cost analysis are expressed in terms of total cost-effectiveness, in dollars per ton of emissions reduced. A relevant consideration in a cost-effectiveness calculation is the economic condition of the industry (or individual facility if the analysis is performed on that basis). Even though a given cost-effectiveness value may, in general, be considered "acceptable," certain industries may find such a cost to be overly burdensome. This is particularly true for well-established industries with low profit margins. Industries with a poor economic condition may not be able to install controls to the same extent as more robust industries. A thorough economic review of the source categories selected for the factor analysis is beyond the scope of this project.

2.2 Factor 2 – Time Necessary for Compliance

For Factor 2, we evaluated the amount of time needed for full implementation of the different control strategies. The time for compliance was defined to include the time needed to develop and implement the regulations, as well as the time needed to install the necessary control equipment. The time required to install a retrofit control device includes time for capital procurement, device design, fabrication, and installation. The Factor 2 analysis also included the time required for staging the installation of multiple control devices at a given facility.

2.3 Factor 3 – Energy and Other Impacts

Table 2-1 summarizes the energy and environmental impacts analyzed under Factor 3. We evaluated the direct energy consumption of the emission control device, solid waste generated, wastewater discharged, acid deposition, nitrogen deposition, and climate impacts (e.g., generation and mitigation of greenhouse gas emissions).

In general, the data needed to estimate these energy and other non-air pollution impacts were obtained from the cost studies which were evaluated under Factor 1. These analyses generally quantify electricity requirements, steam requirements, increased fuel requirements, and other impacts as part of the analysis of annual operation and maintenance costs.

Costs of disposal of solid waste or otherwise complying with regulations associated with waste streams were included under the cost estimates developed under Factor 1, and were evaluated as to whether they could be cost-prohibitive or otherwise negatively affect the facility. Energy needs and non-air quality impacts of identified control technologies were aggregated to estimate the energy impacts for the specified industry sectors. However, indirect energy impacts were not considered, such as the different energy requirements to produce a given amount of coal versus the energy required to produce an equivalent amount of natural gas.

Table 2-1 Summary of Energy and Environmental Impacts Evaluated Under Factor 3

Energy Impacts
Electricity requirement for control equipment and associated fans
Steam required
Fuel required
Environmental Impacts
Waste generated
Wastewater generated
Additional carbon dioxide (CO_2) produced
Reduced acid deposition
Reduced nitrogen deposition
Benefits from reductions in $PM_{2.5}$ and ozone, where available
Impacts Not Included
Impacts of control measures on boiler efficiency
Energy required to produce lower sulfate fuels
Secondary environmental impacts to produce additional energy (except CO_2) produced

2.4 Factor 4 – Remaining Equipment Life

Factor 4 accounts for the impact of the remaining equipment life on the cost of control. Such an impact will occur when the remaining expected life of a particular emission source is less than the lifetime of the pollution control device (such as a scrubber) that is being considered. In this case, the capital cost of the pollution control device can only be amortized for the remaining lifetime of the emission source. Thus, if a scrubber with a service life of 15 years is being evaluated for a boiler with an expected remaining life of 10 years, the shortened amortization schedule will increase the annual cost of the scrubber.

The ages of major pieces of equipment were determined where possible, and compared with the service life of pollution control equipment. The impact of a limited useful life on the amortization period for control equipment was then evaluated, along with the impact on annualized cost-effectiveness.

3. Boilers

A four factor analysis was performed on three coal-fired boilers; two units at Antelope Valley Station (Units B1 & B2), and one unit at Coyote Station, and three waste gas/liquid boilers at the Dakota Gasification Company. The boilers at Antelope Valley and Coyote are used to produce steam from the combustion of lignite coal to generate electricity in a steam turbine. The units at the Antelope Valley Station are rated at 450 megawatts (MW), and the unit at Coyote Station is rated at 427 MW. Pollutant emissions from the boilers include: nitrogen oxides (NO_X), sulfur dioxide (SO_2), and particulate matter (PM). The boilers at Dakota Gasification are used to combust off-gas and waste liquids to provide process steam for the facility. Each of the boilers is rated at 763 MMBtu/hr and is vented to a common exhaust stack. In addition to the emissions from the three boilers, two superheaters rated at 169 MMBtu/hr are also vented to this common exhaust stack.

Table 2-1 summarizes the NO_X and SO_2 emissions from each of the boilers, as well as the control measures used to reduce these pollutant emissions.[1] The pollutant emission rates shown in Table 2-1 were obtained from the North Dakota Department of Health, Division of Air Quality.[2] The pollutant emissions are the based on the average of the two highest annual emission rates from the last five years. For the Dakota Gasification facility, the annual emissions were presented for the common exhaust stack, which includes the pollutant emissions from the three boilers and two superheaters. To estimate the emissions from each boiler, the total emission for each pollutant was divided by the total heat input and hours of operation of the boilers and superheaters to develop emission factors for each pollutant. The emission factors were used to estimate the pollutant emissions for each of the boilers based on the heat input to the boiler and the average hours of operation. Emissions of EC and OC can be estimated using speciation factors from EPA's SPECIATE database.[3] The EC and OC components are estimated to comprise 0.021% and 0.012% of PM_{10} emissions from the coal-fired boilers, respectively. There is not enough information to determine the speciation weight percentages for the Dakota Gasification facility, because the facility combusts waste liquid and gas streams from the facility processes.

Table 3-1. Emissions from Selected Boilers - North Dakota

Source Name	Facility Name	Unit ID	Unit Type	Boiler Size (MMBtu/hr)	NO_X Annual Emissions (tons/yr)	SO_2 Annual Emissions (tons/yr)	PM Annual Emissions (tons/yr)
Basin Electric Power	Antelope Valley Station	Unit B1	Lignite coal-fired boiler equipped with OFA, dry scrubber, FF	6,275	7,625	8,117	397
		Unit B2	Lignite coal-fired boiler equipped with OFA, dry scrubber, FF	6,275	6,764	7,298	390
Otter Tail Power Company	Coyote Station	Unit 1	Lignite coal-fired cyclone boiler equipped with dry scrubber, FF	5,800	13,058	14,864	273
Dakota Gasification Co.	Great Plains Synfuels Plant	Unit A[1]	Waste gas/liquid boiler equipped with wet ESP, and wet FGD	763	935	723	65
		Unit B[1]	Waste gas/liquid boiler equipped with wet ESP, and wet FGD	763	935	723	65
		Unit S[1]	Waste gas/liquid boiler equipped with wet ESP, and wet FGD	763	935	723	65

[1] The available pollutant emissions included the emissions for all three boilers rated at 763 MMBtu/hr and two superheaters rated at 169 MMBtu/hr. To estimate the pollutant emissions for each of the boilers the heat inputs and annual operation of the boilers and superheaters were used to develop emission factors. The emission factors were then used to estimate the individual boiler pollutant emissions.

Currently, the Antelope Valley units are equipped with overfire air, dry scrubber and fabric filter to reduce pollutant emissions. The dry scrubber is used to reduce emissions of SO_2 from the exhaust gas and the FF is used to reduce PM, EC, and OC emissions. The units at Antelope Valley are also equipped with OFA to reduce emission of NO_X from the boilers. The Coyote Station boiler is a cyclone unit equipped with a dry scrubber (DSI) and fabric filter (FF). The Dakota Gasification facility is equipped with wet flue gas desulfurization (FGD) and wet electrostatic precipitator (ESP). A list of potential NO_X and SO_2 control strategies are presented in Table 2-2. The table provides the potential emission reductions for each of the control options.[4,5] For NO_X, the emissions reductions assumes the control option is used in conjunction with the current NO_X control technology. For SO_2, the potential emission reduction is calculated assuming a Wet FGD replaces the current SO_2 control technology. These control options have been applied to many electrical generating unit boilers in the U.S. to reduce emissions of NO_X and SO_2. In Table 2-2, the baseline emissions for NO_X are presented as the average of the two highest annual emission rates over the past five years. The uncontrolled emissions for SO_2 are estimated using an AP-42 emission factor of 30S, and assuming a heat rate of 10,400 Btu/Kw-hr for Antelope Valley and 11,400 Btu/Kw-hr for Coyote Station, a coal sulfur content of 0.6%, and operating 8760 hr/yr. The SO_2 emissions at Dakota Gasification are presented as controlled. The boilers are already equipped with wet FGD which achieves the highest potential SO_2 reduction of any of the control options.

Table 3-2. Control Options for Selected Boilers - North Dakota

Facility Name	Source Type	Pollutant controlled	Control Technology	Uncontrolled emissions[1] (tons/yr)	Annual Emissions (tons/yr)	Estimated control efficiency (%)	Potential emissions reductions[2] (tons/yr)
Antelope Valley Station - Unit B1	Lignite coal-fired boiler equipped with OFA, dry scrubber, FF	NO_X	LNB	12,093	7,625	30 - 75	5,719
			SNCR			30 - 75	5,719
			SCR			40 - 90	6,863
		SO_2	Wet FGD	31,057	8,117	90	5,011

			SCR			40 - 90	842

[1] NO_X uncontrolled emissions calculated using AP-42 emission factors for lignite combustion. SO_2 uncontrolled emissions were calculated using an AP-42 SO_2 emission factor of 30S and assuming 0.6% Sulfur coal.

[2] Potential NO_X emission reductions were calculated assuming the addition of the control options with the existing control technology and assuming the highest percent reduction in the estimated control efficiency range. Potential SO_2 emission reductions were calculated assuming the replacement of the current SO_2 control system with a more effective SO_2 control system.

3.1 Factor 1 – Costs

Table 2-3 provides cost estimates for the emission control options which have been identified for each of the electrical generating unit boilers. Each of the boilers are already equipped with effective PM control, therefore additional PM options were not explored for these boilers. For the NO_X and SO_2 options, the table gives an estimate of the capital cost to install the necessary equipment, and the total annual cost of control, including the amortized cost associated with the capital equipment cost. The capital cost values are expressed in terms of the cost per MW size of the boiler using EPA cost information.[6,7] The capital cost data was extrapolated to determine the capital cost for the larger sized boilers. The annual cost was calculated by amortizing the capital cost over 30 years at an interest rate of 7% and multiplying that value by an O&M factor. Table 2-3 also estimates the cost effectiveness for each control measure, in terms of the cost per ton of emission reduction. Table 2-3 also estimates the cost effectiveness for each control measure, in terms of the cost per ton of emission reduction. Recent literature[8] has indicated that the cost of SCR for electric generating units can vary from $150 to $300 per kilowatt, therefore due to this variability, the capital and annual costs for SCR are presented as a range.

Emissions used to estimate the cost effectiveness of the control options were obtained from Table 3-2. For NO_X, the emissions used for the cost effectiveness calculations were the controlled emission rates. The NO_X controlled emission rates were used because the currently installed NO_X controls can be used in conjunction with the listed control options to reduce NO_X emissions from the current levels. For SO_2, uncontrolled emission levels were estimated for the coal-fired boilers to compare the current SO_2 emission levels with potential SO_2 emission reductions using the listed control technologies.

It should be noted that the application of high dust SCR may not be technically feasible for use on the lignite coal-fired boilers. The lignite coal contains a higher ash content which causes catalyst deactivation and air heater corrosion/blockage. In addition, the higher organically associated sodium in the lignite coal also deactivates the catalyst rapidly. Therefore, each boiler should be evaluated to determine the technical feasibility of applying high dust SCR to control emissions of NO_X.

3.2 Factor 2 – Time Necessary for Compliance

Once a State decides to adopt a particular control strategy, up to 2 years will be needed to develop the necessary rules to implement the strategy. We have estimated that sources may then require up to a year to procure the necessary capital to purchase control equipment. The Institute of Clean Air Companies (ICAC) has estimated that approximately 18 months is required to design, fabricate, and install SCR or SNCR technology for NO_X control, and approximately 30 months to design, build, and install SO_2 scrubbing technology.[9] Additional time of up to 12 months may be required for staging the installation process if multiple boilers are to be controlled at a single facility. Based on these figures, the total time required to achieve emission reductions for industrial boilers is estimated at a total of 5½ years for NO_X strategies, and 6½ years for SO_2 strategies.

3.3 Factor 3 – Energy and Other Impacts

Table 2-4 shows the estimated energy and non-air pollution impacts of control measures for industrial boilers. The values were obtained the EPA report listing the performance impacts of each of the control technology options.[10,11] In general, the combustion modification technologies (LNB, OFA) do not require steam or generate solid waste, or wastewater. They also do not require additional fuel to operate, and in some cases may decrease fuel usage because of the optimized combustion of the fuel.

Retrofitting of a SNCR requires energy for compressor power and steam for mixing. This would produce a small increase in CO_2 emissions to generate electricity; however the technology itself does not produce additional CO_2 emissions.

Installation of SCR on an industrial boiler is not expected to increase fuel consumption. However, additional energy is required to operate the SCR, which will produce an increase in CO_2 emissions to generate the electricity. In addition, spent catalyst would have to be changed periodically, producing an increase in solid waste disposal. However, many catalyst companies accept the return of spent catalyst material.

Table 3-3. Estimated Costs of Control for Selected Boilers - North Dakota

Facility Name	Pollutant controlled	Control Technology	Estimated control efficiency (%)	Estimated capital cost ($1000)	Estimated annual cost ($1000/yr)	Cost effectiveness ($/ton)
Antelope Valley Station - Unit B1	NO_X	LNB	51	14,530	2,280	586
		SNCR	40	15,020	8,960	2,938
		SCR	80	67,500 - 135,000	16,966 - 33,932	2,781 - 5,563
	SO_2	Wet FGD	90	170,100	32,170	6,420
Antelope Valley Station - Unit B2	NO_X	LNB	51	14,530	2,280	661
		SNCR	40	15,020	8,960	3,312
		SCR	80	67,500 - 135,000	16,966 - 33,932	3,135 - 6,271
	SO_2	Wet FGD	90	170,100	32,170	7,674
Coyote Station - Unit 1	NO_X	SNCR	40	14,270	8,520	1,631
		SCR	80	64,050 - 128,100	16,099 - 32,198	1,541 - 3,082
	SO_2	Wet FGD	90	161,700	30,580	2,550
Great Plains Synfuels Plant - Unit A	NO_X	SNCR	40	2,840	1,690	4,519
		SCR	80	10,950 - 21,900	2,752 - 5,505	3,680 - 7,359
Great Plains Synfuels Plant - Unit B	NO_X	SNCR	40	2,840	1,690	4,519
		SCR	80	10,950 - 21,900	2,752 - 5,505	3,680 - 7,359
Great Plains Synfuels Plant - Unit S	NO_X	SNCR	40	2,840	1,690	4,519
		SCR	80	10,950 - 21,900	2,752 - 5,505	3,680 - 7,359

[1] The annual cost was calculated using a 30-year equipment life and 7% interest.

[2] NO_X cost effectiveness is calculated from annual emissions using the estimated control efficiency and assumes that the control option is used in conjunction with the current NO_X control. SO_2 cost effectiveness is calculated using the potential emission reductions and reflects the replacement of the current SO_2 control with a Wet FGD.

Retrofitting of the SO_2 control options increase the usage of electricity, and produce both a solid waste and wastewater stream. In addition, increases of CO_2 emission will occur due to the increased energy usage for material preparation (e.g., grinding), materials handling (e.g., pumps/blowers), flue gas pressure loss, and steam requirements. Power consumption is also affected by the reagent utilization of the control technology, which also affects the control efficiency of the control technology.

3.4 Factor 4 – Remaining Equipment Life

Electric generating units do not have a set equipment life. Since many of the strategies are market-based reductions applied to geographic regions, it is assumed that control technologies will not be applied to units that are expected to be retired prior to the amortization period for the specific control equipment. Therefore, the remaining life of an industrial boiler is not expected to affect the cost of control technologies for industrial boilers.

Table 3-4. Estimated Energy and Non-Air Environmental Impacts of Potential Control Measures for Selected Boilers - North Dakota

			Energy and non-air pollution impacts				
Source Type	Control Technology	Pollutant controlled	Electricity requirement (kW)	Steam requirement (lb/hr)	Solid waste produced (ton/hr)	Wastewater produced (gal/min)	Additional CO_2 emitted (tons/yr)

4. Natural Gas Processing Facilities

Four-factor analyses have been conducted for selected emission sources at the Hess Corporation Tioga Gas Plant, in Williams County, North Dakota, and the Petro Hunt Little Knife Gas Plant in Billings County, North Dakota. The following emission sources have been evaluated:

- Petro Hunt Little Knife Gas Plant
  - Sulfur recovery unit (SRU) for amine treatment unit #1
- Hess Corporation Tioga Gas Plant
  - SRU for amine treatment unit #1
  - Seven lean-burn natural gas-fired compressor engines – five at 1,920 horsepower (hp) and two at 2,350 hp

Table 4-1 outlines the emission control measures that have already been applied to these sources, the baseline levels of emissions with these current controls, and potential additional control measures that could be adopted to further reduce emissions. The table also gives the estimated control efficiency and annual emission reduction for each potential future control measure.

Information on existing control measures and baseline emission levels for the North Dakota facilities was obtained from the North Dakota Department of Health.[1] The baseline emission level for each source reflects the average of the two highest annual emission rates over the past five years.

The Petro Hunt Little Knife plant has a 3-stage SRU with a cold bed adsorption (CBA) control system. The SRU has a capacity of 120 long tons sulfur per day and an estimated overall recovery efficiency of over 98%. The Hess Tioga plant has a 2-stage Claus SRU, also with a CBA control system. This unit has a capacity of 225 long tons of sulfur per day and an overall recovery efficiency of over 97%.

The New Source Performance Standards (NSPS) for sulfur recovery units at petroleum refineries limit SO2 emissions to 250 ppm, which corresponds to an overall efficiency of 99.98% (from the uncontrolled flow rate of sulfur compounds in the SRU feed stream).[2] This emission rate is generally achieved using tail gas treatment technologies.[3] EPA's RACT/BACT/LAER Clearinghouse indicates that tail gas treatment units (TGTU) installed on sulfur recovery units at petroleum refineries in recent years typically are required to achieve a controlled SO_2 emission concentration of 150 ppm,[4] which corresponds to an overall efficiency of 99.988%. Therefore, it is expected that TGTUs applied to the Petro Hunt and Hess SRUs could achieve an overall sulfur removal efficiency of between 99.98% and 99.988%. This would correspond to a reduction of

Table 4-1. Existing Control Measures and Potential Additional Control Options for Selected Natural Gas Processing Operations in North Dakota

		OC		1.5			1.5	

about 87 to 92% for the Petro Hunt facility (assuming a baseline efficiency of 98.5%), 92 to 95% for the Hess facility (assuming a baseline efficiency of 97.5%).

The Hess Tioga facility uses five 1,920 hp reciprocating engines and two 2,350 hp reciprocating engines, all fueled by natural gas in a under lean-burn fueling mode. The two 2,350 hp engines have recently been refurbished, and the reported NO_X emissions from these engines are about 70% lower than the reported emissions from the 1,920 hp engines, or a mass per hp-hour basis.

A number of options have been identified for stationary reciprocating engines in an Alternative Control Techniques (ACT) guidance document written by the U.S. EPA in 1993, and in more recent analyses for New Source Performance Standards.[5,6] In addition, the WRAP sponsored a study of control options for engines used in the oil and gas industry.[7] Reciprocating engines can be designed to operate under rich fuel mixture, or lean fuel mixture conditions. Air-to-fuel-ratio adjustments and ignition retarding technologies can be used to control emissions under either fuel mixture condition. Low-Emission Combustion (LEC) retrofit technology which can also reduce emissions from reciprocating engines by an average of 89%.[8] LEC involves modifying the combustion system to achieve very lean combustion conditions (high air-to-fuel ratios). SCR can also be used either alone or in conjunction with the above technologies to reduce NO_X emissions from reciprocating engines or turbines by 90%. EPA prepared an update to the ACT guidance for reciprocating engines in 2002 which focused on LEC technology and also updated the analysis of SCR.

For the two 2,350 hp engines, we have adjusted the estimated efficiencies of potential future control measures to reflect the emission reduction which appears to have already achieved by the recent refurbishment. We have assumed that air-to-fuel ratio adjustments, ignition timing retarding, and LEC retrofit technology would not achieve further emission reductions, since the estimated emission reductions for these measures are less than the reductions which appear to have already been achieved.

4.1 Factor 1 – Costs

Table 4-2 provides cost estimates for the emission control options which have been identified for the North Dakota gas processing facilities. For each option, the table gives an estimate of the capital cost to install the necessary equipment, and the total annual cost of control, including the amortized cost associated with the capital equipment cost. The table also shows the estimated cost effectiveness for each control measure, in terms of the cost per ton of emission reduction.

Costs for the SRU tail gas treatment units were estimated using data given capital and annual cost data provided a review of the NSPS for Claus SRUs.[2] The NSPS analysis gives costs for three model plant sizes, which were interpolated to estimate costs for plants in the size ranges of the Petro Hunt and Hess SRUs (120 and 225 long tons per day, respectively).

Table 4-2. Estimated Costs of Control for Selected Natural Gas Processing Operations in North Dakota

Company	Source	Control option	Pollutant	Estimated control efficiency (%)	Potential emission reduction (tons/year)	Estimated capital cost ($1000)	Estimated annual cost ($1000/year)	Cost effectiveness ($/ton)	Refer-ences
Petro Hunt, Little Knife Gas Plant	Sulfur recovery unit, 3-stage, 4-bed, 120 long tons/day sulfur	Tail gas treatment unit - amine absorption	SO_2	87 - 92	370 - 400	9,400	3,200	8,060 - 8,560	2,3

			EC	100	2			60,870	
			OC	100	2			93,330	
			Overall	100	226			619	

Costs for the reciprocating engine controls were estimated using data provided in the EPA ACT document, the ACT update, and the WRAP analysis for oil and gas production.[5,7,8] These sources give equations which relate capital and annual costs of emission controls to engine size in hp. The equations were applied to the engine sizes at the Hess Tioga plant.

4.2 Factor 2 – Time Necessary for Compliance

Once the regional haze control strategy is formulated for North Dakota, up to 2 years will be needed for the state to develop the necessary rules to implement the strategy. We have estimated that sources may then require up to a year to procure the necessary capital to purchase control equipment. The ICAC has estimated that approximately 13 months is required to design, fabricate, and install SCR or SNCR technology for NO_X control.[9] However, state regulators' experience indicates that closer to 18 months is required to install this technology.[10] In the Clean Air Interstate Rule (CAIR) analysis, EPA estimated that approximately 30 months is required to design, build, and install SO_2 scrubbing technology for a single emission source.[11] The analysis also estimated that up to an additional 12 months may be required for staging the installation process if multiple sources are to be controlled at a single facility.

Based on these figures, the total time required achieve emission reductions for the Petro Hunt facility would be up to 6½ years. This includes 2 years for regulatory development, 1 year for capital acquisition, and 2½ years for designing, building and installing the TGTU. The time to achieve emission reductions for the Hess facility would also be up to 6½ years. This estimate includes the same components as the estimate for Petro Hunt, with an additional year for staging the installation of controls for multiple emission sources (the SRU and the reciprocating engines.)

4.3 Factor 3 – Energy and Other Impacts

Table 4-3 shows the estimated energy and non-air pollution impacts of control measures for sources at the Petro Hunt and Hess facilities. The table shows the additional fuel, electricity, and steam requirements resulting required to operate the control equipment; and the additional solid waste would be produced. CO_2 emissions associated with the generation of the additional electricity and steam are also estimated in the table.

The electricity and steam requirements for sulfur recovery TGTUs are based operating parameters from the 1982 NSPS review analysis.[2] These energy requirements are high in relation to the SO_2 emission reduction. Operating parameters were not readily available for newer TGTU designs; however, the energy requirement of these systems may be lower than the 1982 design.

Table 4-3. Estimated Energy and Non-Air Environmental Impacts of Potential Control Measures for Selected Natural Gas Processing Operations in North Dakota

Source Type		Control Technology	Pollutant controlled	Potential emission reduction (tons/year)	Additional fuel requirement (%)	Energy and non-air pollution impacts (per ton of emission reduced)			
						Electricity requirement (kW-hr)	Steam requirement (tons steam)	Solid waste produced (tons waste)	Additional CO_2 emitted (tons)
Petro Hunt, Little Knife Gas Plant	Sulfur recovery unit, 3-stage, 4-bed, 120 long tons/day sulfur	Amine absorption	SO_2	370 - 400		2,200	210	0.01	57
Hess Corp., Tioga Gas Plant	Sulfur recovery unit, 2-bed Claus, 225 long tons/day sulfur	Amine absorption	SO_2	1,120 - 1,160		700	120	0.004	32
	Five natural gas fired reciprocating engines, 1,920 hp each, 2-stroke lean burn (Clark Model HLA-8)	Air-fuel ratio	NO_X	160 - 630	2.5				1.9
		Ignition timing	NO_X	230 - 470	2.5				1.9
		LEC retrofit	NO_X	1,300 - 1,400	a				
		SCR	NO_X	1,300 - 1,400	0.5				0.4
		Replacement with electric motors	NO_X	1,600	(100)	66,000			b
			$PM_{2.5}$, PM_{10}, EC, OC	10					b
			Total	1,610					b
	Two natural gas fired reciprocating engines, 2,350 hp each, 2-stroke lean burn (Clark Model HLA-8, recently refurbished)	SCR	NO_X	71 - 140	0.5				0.0
		Replacement with electric motors	NO_X	220	(100)	66,000			b
			$PM_{2.5}$, PM_{10}, EC, OC	6					b
			Total	226					b

NOTES:

a - The measure is expected to improve fuel efficiency.

b - CO_2 from the generation of electricity would be offset by avoided emissions due to replacing the diesel engine

blank indicates no impact is expected.

For gas-fired reciprocating engines and diesel engines, air-to-fuel-ratio adjustments and ignition retarding technologies have been found to increase fuel consumption by up to 5%, with a typical value of about 2.5%.[12,13] This increased fuel consumption would result in increased CO_2 emissions. LEC technology is not expected to increase fuel consumption; and may provide some fuel economy.[12]

Installation of SCR on the reciprocating engines would cause a small increase in fuel consumption, about 0.5%, in order to force the exhaust gas through the catalyst bed.[12] This would produce an increase in CO_2 emissions to generate the electricity. In addition, spent catalyst would have to be changed periodically, producing an increase in solid waste disposal.[14]

4.4 Factor 4 – Remaining Equipment Life

The startup dates for the emission sources at the Petro Hunt and Hess natural gas facilities are as follows:

- Petro Hunt Little Knife Plant
  - SRU – 1983
- Hess Tioga Plant
  - SRU – 1991
  - 1,920 hp engines – 1954
  - 2,350 hp engines – 1954

It is not possible to compute the remaining service lifetimes of these sources since emission sources at industrial facilities are often refurbished. For instance, the 2,300 hp engines at Hess were recently refurbished, although they are over 50 years old. Therefore, the remaining lifetimes of the SRUs and compressors are expected to be longer than 15 year figure which has been used to amortize the capital costs of add-on emission controls or equipment modifications to reduce emissions.

If the remaining life of an emission source is less than the projected lifetime of a pollution control device, then the capital cost of the control device would have to be amortized over a shorter period of time, corresponding to the remaining lifetime of the emission source. This would cause an increase in the amortized capital cost of the pollution control option, and a corresponding increase in the total annual cost of control. This increased cost can be quantified as follows:

$$A_1 = A_0 + C \times \frac{1-(1+r)^{-m}}{1-(1+r)^{-n}}$$

where:

A_1 = the annual cost of control for the shorter equipment lifetime ($)
A_0 = the original annual cost estimate ($)
C = the capital cost of installing the control equipment ($)

r = the interest rate (0.07)
m = the expected remaining life of the emission source (years)
n = the projected lifetime of the pollution control equipment

Mr. Lee Gribovicz
Western Regional Air Partnership (WRAP)
1600 Broadway, Suite 1700
Denver, CO 80202

Dear Mr. Gribovicz:

Basin Electric Power Cooperative (Basin Electric) is a consumer-owned, regional cooperative headquartered in Bismarck, North Dakota. Basin Electric has reviewed the Draft Report titled *"Supplementary Information for Four-Factor Analyses for Selected Individual Facilities in North Dakota"* dated May 18, 2009, and have the following comments for your consideration.

Page ii: You state in your Scope of Document Section that:

"This document provides an initial analysis of the four factors which must be considered in establishing a reasonable progress goal toward achieving natural visibility conditions in mandatory Class I areas".

We would like to point out that there is regulatory defined fifth factor that must be a part of this analysis. Any determination for the application of additional controls to reduce primary pollutants must further consider the degree of visibility improvement on a deciview (dv) and cost per deciview basis ($/dv) that would occur by the implementation of any controls. We recognize the document may have been directed to address the first four aspects of the evaluation process. We feel the fifth fact is of greater importance and is more consistent with the language and intent of the law. Further, the analysis must consider the impacts of all sources impacting visibility, and must be fair and non-discriminatory between source types, and should not simply tart energy generation units.

Page 3-2,3-5 and 3-6: Mismatch of text and titles of Table's 3-1, 3-2 and 3-3. They should be Table 2-1, 2-2 and Table 2-3 or correct text.

Page 3-3 Table 3-2 Control Options for Selected Boilers – North Dakota indicates the SO_2 control technology to be evaluated over and above the existing technology of Dry Scrubber would be Wet FGD technology. Basin Electric believes there are potential intermediate improvements steps associated with Dry FGD technology that should also be evaluated.

Page 3-4 We agree on your discussion on the application of SCR on North Dakota Lignite coal-fired boilers may not be technically feasible. You further state that each boiler should be evaluated to determine this technical feasibility. At the point in time where the utilities are required to perform the case-by-case technical evaluation for all additional pollution control equipment, the current body of knowledge will be utilized to make this technical and economic evaluation. Again the actual amount of visibility improvement on an incremental basis (both on dv and $/dv) from the next level of control technology will need to apart of the final evaluation process.

Page 3-4 Time Necessary for Compliance: We generally agree with your assessment of the five to six years to achieve emission reductions; however our units' major unit outages (6-8 weeks) are scheduled every three years. Depending on how the regulatory process unfolds with the outage schedules, the overall implementation timeline may need to be increased.

Basin Electric appreciates the opportunity to comment on your efforts.

Sincerely,

Cris Miller for

Mr. Lee Gribovicz, Project Manager
Western Regional Air Partnership
1600 Broadway, Suite 1700
Denver, Colorado 80202

Dear Mr. Gribovicz:

Thank you for the opportunity to provide comments on the document created for Western Regional Air Partnership (WRAP) entitled "Supplementary Information for Four-Factor Analyses for Selected Individual Facilities in North Dakota." The Four-Factor Analyses, hereafter referred to as the WRAP document, references the Riley boilers at the Great Plains Synfuels Plant (GPSP) and makes a case for why Selective Catalytic Reduction (SCR) or Selective Non-Catalytic Reduction (SNCR) should be considered in setting reasonable progress goals to reduce NO_x emissions and improve regional haze. Dakota Gasification Company (DGC) supports the document presumption that the facility already meets the requirements for sulfur reduction technologies.

DGC is concerned about the high capital and operating costs associated with the NO_x removal technologies outlined in the WRAP document. Additionally, DGC is concerned that the capital cost and operating cost outlined in this report may be somewhat underestimated because it has not accounted for the unique operation at the GPSP. Finally, DGC is concerned that the estimated control efficiency may be overstated relative to the capital expended.

Theoretically, SCR and SNCR appear to be good technologies for controlling NO_x from the Riley boilers; however, neither has been proven to work with DGC's unique boiler fuels. The Riley boilers are fired with a variety of liquid *and* gaseous lignite-derived fuels. The capital and operating cost referenced in the WRAP document is based on either liquid-fired *or* gas-fired boilers. The reference does not address the cost implications for the unique combination of fuels fired at the GPSP.

DGC is not certain that SCR is technically feasible with the existing process at the GPSP. Furthermore, DGC has information that the cost may be significantly higher than reported in the WRAP document. In 1996, DGC installed a Flue Gas Desulfurization Unit as Best Achievable Control Technology (BACT) for sulfur dioxide. During the evaluation process leading up to the BACT installation, DGC evaluated a proposal for SCR on the Riley boilers. The proposal would have required modifications to the heat recovery section of the Riley boilers to increase the temperature of the flue gas entering the SCR. Presumably, the current operating temperature is not sufficient for effective SCR operation.

The required modifications would have reduced the capability of the boilers to make enough steam to operate the facility at full production. Therefore, the cost estimates in the WRAP document for installing SCR at DGC are too low because they do not account for the capital costs associated with modifying the Riley boilers and the production lost during that effort. Additionally, the operating cost estimates do not account for the continuing plant production losses directly related to the reduction in steam capacity from the Riley boilers.

Regarding SNCR, DGC has information that suggests it may not be technically feasible at DGC's GPSP. In 1997, DGC experimented with SNCR as a NO_x control on the Riley boilers. The injection of ammonia during this testing resulted in the rapid accumulation of ammonium sulfate particulate deposits in the heat recovery section of the boiler. The uniqueness of the flue gas (high SO_2 and CO_2) is believed to have contributed to the formation of ammonium sulfate in the boilers. This highly undesirable side effect combined with a much lower than predicted NO_x reduction prompted DGC to immediately discontinue testing. Further testing was not performed due to the likelihood of interfering with the long-term reliability and performance of the Riley boilers.

In addition to the typical cost of the control technologies themselves, other costs of installing SCR or SNCR will include engineering challenges of finding a place to install equipment in an area with limited space available. DGC has the concern that a retrofit installation for SNCR or SCR would drive the costs higher than the costs noted in the high level overview provided in the WRAP document. The reference for the WRAP document does not clearly indicate if a congested work site comparable to that at DGC has been considered in the capital cost estimate.

The WRAP document based the capital cost, operating cost, and overall effectiveness of the control technology by applying control technology only to the Riley boilers and not the two liquid-fired superheaters. This is an understandable approach by the author because the superheaters are equivalent to only 10% of the Riley boiler heat load. However, DGC's sampling indicates that the superheaters could contribute over 20% of the total NO_x produced. In order to achieve the maximum NO_x control referenced in the WRAP document, DGC would have to expend additional costs for controls on the superheaters.

Any new technology that is considered for NO_x controls will require an evaluation. Depending on the technology chosen, time and resources may need to be allotted to construct and operate a pilot plant to prove a chosen technology will work in this application.

Before requiring expenditure of significant amounts of capital to install new emission controls, consideration should be given to the overall impact of any required emission reduction. The NO_x emissions from the GPSP are a small part of the state inventory. Therefore, it does not seem cost-effective that DGC should bear the expense of adding costly controls. Good emission control strategies should target regional sources that are more cost-effective and feasible.

In addition to the four-factor analysis, a fifth factor needs to be part of this analysis. Any determination for the application of additional controls to reduce primary pollutants must further consider the degree of visibility improvement on a deciview (dv) and cost per dv ($/dv) basis that would be incurred by the implementation of any controls. This factor is of great importance and should be a major consideration.

If an emission reduction is required for a facility, DGC suggests that the agency issuing the requirement explain what reductions are needed and how those reductions are considered to be possible based on technology available. The agency should also allow facilities the flexibility to identify new and innovative ways to achieve those reductions that may not have been initially considered in the WRAP document.

DGC appreciates your consideration of our comments. Given the reasons detailed in this letter, DGC believes the control technologies for SCR and SNCR on the GPSP Riley boilers should not be considered within the first State Implementation Plan (SIP) on Regional Haze.

Sincerely,

David W Peightal

Subject: Comments - EC/R Inc. Four Factors Analysis - Hess Corporation Tioga Gas Plant

Mr. Gribovicz,

A review of the Hess Corporation Tioga Gas Plant data contained in the Four-Factor Analyses for Selected Individual Facilities in North Dakota report was recently completed. Our comments regarding the Tioga Plant analyses follow:

SO2 Emissions - Sulfur Recovery Unit (SRU):

The average sulfur recovery efficiency for the Tioga Gas Plant SRU is 98.8%. The baseline sulfur recovery efficiency stated in the report and used in the economic analysis is 97.5%. This difference in the recovery efficiency impacts the cost analyses. The cost per ton of sulfur dioxide emissions reduced by requiring additional control technology would increase substantially.

The Tioga Gas Plant SRU was designed for 225 long tons per day of sulfur production. The SRU currently recovers less than 100 long tons per day due to a lower sulfur concentration in the plant’s inlet gas. Expectations are the amount of sulfur in the inlet gas will continue to drop as more sweet gas is processed by the plant in conjunction with the Bakken Field development.

The cost estimate for installing a TGTU-amine absorption unit appears to be based on a 1982 report and extrapolating the costs up from a 100 ton per day unit. This could lead to significant error in the cost analysis.

NOx Emissions - Clark Engines:

The configuration of the Clark engine/compressor does not allow for replacement of the engine with an electric motor. The compressor cylinders connecting rods are an integral part of the engine’s main crankshaft.

Selective Catalytic Reduction (Catalytic Converter) will not work to control NOx emissions from a two-cycle lean burn engine without the injection of ammonia upstream. The use of ammonia has additional safety concerns.

If you should have any questions regarding these comments or need additional data, my contact information follows.

OtterTail Comments ECR Inc. Four Factors Analysis

From: TGraumann@otpco.com
Sent: Wednesday, May 27, 2009 9:01 AM
To: lg@westgov.org
Cc: Bachman, Tom A.
Subject: EC/R Inc. Four Factors Analysis
Attachments: ND DOH Regional Haze Progress Goals.xls; ND DOH Regional Haze Progress Goals.xls

Mr. Gribovicz:

Based on previous correspondence from Tom Bachman of the North Dakota Department of Health, it is my understanding that North Dakota must develop Regional Haze Reasonable Progress Goals for the Class I areas in North Dakota. As part of developing the Reasonable Progress Goals, North Dakota is required to evaluate the potential for air pollution controls (or additional controls) at sources that were not subject to Best Available Retrofit Technology (BART) requirements. EC/R, Inc. prepared a draft analysis of those facilities for the WRAP.

One of the facilities that is included in the analyses is Coyote Station, which is a co-owned facility that is operated by Otter Tail Power Company.

I have reviewed the draft report "Supplementary Information for Four-Factor Analyses for Selected Individual Facilities in North Dakota" and I offer the following comments for your consideration.

Section 3 Page 3-2. The fourth line from the bottom of the page references a coal sulfur content of 0.6% as a basis for estimating uncontrolled emissions. The average coal sulfur content for fuel burned at Coyote Station during the last five years (2004-2008) is 1.01%. We suggest using 1.01% for estimating the uncontrolled emissions for Coyote Station.

Section 3 Page 3-3 Table 3-2. The table reflects unrealistically low uncontrolled SO2 emissions and, when compared to the annual emissions, it gives the appearance that Coyote Station is removing less than 50% of the uncontrolled emissions. The table also attributes a greater incremental potential emissions reduction based a 90% control efficiency when compared to current removals. The attached table illustrates our concern. The SO2 uncontrolled of 48,323 tons more accurately reflects estimated historical conditions as does a removal of approximately 69%. The incremental benefit of 90% SO2 removal is reduced from 11,993 tons to 10,032 tons. Note that the methodology for calculating the uncontrolled emissions remains as you have proposed. The revised uncontrolled SO2 was simply based on a ratio of the fuel sulfur content (0.6% to 1.01%).

Section 3 Page 3-4. The second paragraph of the page accurately captures industry concerns with the feasibility of a high duct SCR on a lignite fired boiler. It might be helpful to include a reference supporting that concern. Because of its size I will forward the reference under a separate e-mail.

Section 3 Page 3-5 Table 3-3. As noted above, the incremental benefit of 90% SO2 removal is
reduced from 11,993 tons to 10,032 tons. The cost effectiveness of the wet FGD control
efficiency would increase in inverse proportion to the decrease in the tons of SO2 removed, all
other assumptions remaining equal. Thus the cost effectiveness ($/ton) of 90% SO2 removal
would be $3048 rather than $2550.

I have not reviewed the document for table text references and the like. I did notice that several
of the tables referenced in the text in Section 3 were incorrectly referenced.

Thank you for the opportunity of submitting comments.

Regards,

Terry

JV 31 – EVALUATION OF POTENTIAL SCR CATALYST BLINDING DURING COAL COMBUSTION AND ADD-ON: IMPACT OF SCR CATALYST ON MERCURY OXIDATION IN LIGNITE-FIRED COMBUSTION SYSTEMS

ABSTRACT

Lignite and subbituminous coals from the United States of America have characteristics that impact the performance of catalysts used in selective catalyst reduction (SCR) for nitrogen oxide removal and mercury oxidation. Typically, these coals contain ash-forming components that consist of inorganic elements (sodium, magnesium, calcium, and potassium) associated with the organic matrix and mineral grains (quartz, clays, carbonates, sulfates, and sulfides). Upon combustion, the inorganic components undergo chemical and physical transformations that produce intermediate inorganic species in the form of inorganic gases, liquids, and solids. The alkali and alkaline-earth elements are partitioned between reactions with minerals and reactions to form alkali and alkaline-earth-rich oxides during combustion. The particles resulting from the reaction with minerals produce low-melting-point phases that cause a wide range of fireside deposition problems. The alkali and alkaline-earth-rich oxides consist mainly of very small particles (<5 µm) that are carried into the backpasses of the combustion system and react with flue gas to form sulfates and, possibly, carbonates. These particles cause low-temperature deposition, blinding, and plugging problems in SCR systems. These coals also lack sufficient levels of chlorine needed to oxidize mercury. Slipstream testing was conducted at two subbituminous-fired power plants and one lignite-fired power plant to determine the impacts of ash on SCR plugging, blinding, and mercury oxidation. The results indicated a high potential for blinding and plugging because of the formation of sulfate-bonded deposits but no evidence of mercury oxidation.

JV 31 – EVALUATION OF POTENTIAL SCR CATALYST BLINDING DURING COAL COMBUSTION AND ADD-ON: IMPACT OF SCR CATALYST ON MERCURY OXIDATION IN LIGNITE-FIRED COMBUSTION SYSTEMS

EXECUTIVE SUMMARY

The goal of this project by the Energy & Environmental Research Center (EERC) is to determine the potential of low-rank coal ash to cause blinding or masking of selective catalytic reduction (SCR) catalysts. The primary goal of the add-on is to determine the effects of new and aged catalyst on the oxidation of mercury at full-scale power plants.

Two SCR slipstream reactors were constructed to accomplish the goals of this project. The test chambers are approximately 19 cm (7.5 inches) square and are able to accommodate catalyst sections up to 1 meter (3.3 feet) in length. The chambers are electrically heated and fully instrumented to limit heat loss and to maintain a catalyst face velocity of 5 m/s (16.4 ft/s).

The SCR reactors were installed at three different plant locations and operated until the catalyst had 6 months of operating time. The units that were chosen for this study are the Columbia Station (pulverized coal-fired), the Baldwin Station (cyclone-fired), and the Coyote Station (cyclone-fired). The Coyote Station fires North Dakota lignite, while the other two stations burn Powder River Basin (PRB) coal. The catalyst was sampled every 2 months and analyzed with scanning electron microscopy (SEM).

Bench-scale and Facility for Analysis of Chemical Thermodynamics (FACT) modeling studies were also conducted in the laboratory prior to the reactors being installed at the host utilities. Experiments were carried out in a thermogravimetric analyzer (TGA) system at 315°C (600°F), 370°C (700°F), and 427°C (800°F) with simulated flue gas. Ash samples created from the test coals were placed on the TGA pan with and without catalyst. The rate of sample weight gain was then monitored. The ash was then analyzed with SEM techniques to identify the species that were present.

The results of the bench-scale analysis indicate that the rate of weight gain increases with increasing temperature, and calcium sulfates were the predominant species formed. The rate of sulfate formation could increase as much as tenfold with the addition of catalyst to the system. Low-sulfur bituminous and PRB blends exhibited a higher rate of sulfate formation and, therefore, would have a higher blinding potential than a 100% PRB or lignite. Results of the FACT modeling indicate that there is a high potential to form alkali and alkaline-earth sulfates, carbonates, and phosphates while SCRs are operated at utilities burning lignite and PRB coals.

The data collected during the three slipstream reactor tests indicate that the pressure drop across the catalyst was found to be the most significant for the lignite-fired plant as compared to the subbituminous-fired plants. Both lignite and PRB coals had significant accumulations of ash on the catalyst, on both macroscopic and microscopic levels. On a macroscopic level, there were significant observable accumulations that plugged the entrance as well as the exit of the catalyst

sections. On a microscopic level, the ash materials filled pores in the catalyst and, in many cases, completely masked the pores within 4 months of operation.

The deposits on the surfaces and within the pores of the catalyst consisted of mainly alkali and alkaline-earth element-rich phases that have been sulfated. The mechanism for the formation of the sulfate materials involves the formation of very small particles rich in alkali and alkaline-earth elements, transport of the particles to the surface of the catalyst, and reactions with SO_2/ SO_3 to form sulfates. X-ray diffraction analysis identified $CaSO_4$ as a major phase and $Ca_3Mg(SiO_4)_2$ and $CaCO_3$ as minor phases.

Lignite and subbituminous coals contain high levels of organically associated alkali and alkaline-earth elements, including sodium, magnesium, calcium, and potassium in addition to mineral phases. During combustion, the inorganic components in the coal are partitioned into various size fractions based on the type of inorganic component and their association in the coal and combustion system design and operating conditions. The results of this testing found that the smaller size fractions of ash are dominated by partially sulfated alkali and alkaline-earth elements. The composition of the size fractions was compared to the chemical composition of the ash deposited on and in the catalyst. The comparison shows that the composition of the particle captured in the SCR catalyst is very similar to the <5-µm size fraction.

This study suggests the careful evaluation of each SCR installation on applications using subbituminous and lignite coals. Improvements are needed to ensure technical feasibility, especially with lignite-fired units. Installations involving lignite fuels will need advanced cleaning techniques to handle the high sodium and high dust loads associated with burning most lignite fuels.

The ability of mercury to be oxidized across the SCR catalyst was investigated at the Coyote Station. The Coyote Station is fired on North Dakota lignite, and the flue gases are dominated by elemental mercury. Measurement of mercury speciation was conducted using the Ontario Hydro (American Society for Testing and Materials D6784-02) method at the inlet and the outlet of the SCR reactor. These results show limited oxidation of mercury across the SCR catalyst when lignite coals are fired. The reasons for the lack of mercury oxidation include the following: no chlorine present in the coal and flue gas to catalytically enhance the oxidation of Hg^0, higher levels of alkali and alkaline-earth elements acting as sorbents for any chlorine present in the flue gas, and lower levels of acid gases present in the flue gas.

JV 31 – EVALUATION OF POTENTIAL SCR CATALYST BLINDING DURING COAL COMBUSTION AND ADD-ON: IMPACT OF SCR CATALYST ON MERCURY OXIDATION IN LIGNITE-FIRED COMBUSTION SYSTEMS

INTRODUCTION

The Energy & Environmental Research Center (EERC) investigated selective catalytic reduction (SCR) for NO_x control and mercury oxidation using a slipstream reactor at power plants firing subbituminous and lignite coals to determine the potential for ash plugging and blinding and mercury oxidation. SCR units lower NO_x emissions by reducing NO_x to N_2 and H_2O. Ammonia (NH_3) is the most common reducing agent used for the SCR of NO_x. The SCR process involves the use of a metal oxide catalyst such as titanium dioxide (TiO_2)-supported vanadium pentoxide (V_2O_5). These units are operated at about 340°–370°C (650°–700°F). Subbituminous and lignitic coals are known for their ability to produce alkali and alkaline-earth sulfate-bonded deposits at low temperature (<1000°C) in utility boilers. The mechanisms of the formation of low-temperature sulfates have been extensively examined and modeled by the EERC in work termed Project Sodium and Project Calcium in the early 1990s (1, 2). Deposit buildup of this type blinds or masks the catalyst, diminishing its reactivity for converting NO_x to N_2 and water and potentially creating increased NH_3 slip (3). Elemental mercury oxidation has been observed in laboratory-, pilot-, and full-scale testing using SCR catalysts (4–6). In these studies, the metal oxides, V_2O_5 and TiO_2, have been shown to promote the conversion of elemental mercury to oxidized and/or particulate-bound mercury. Full-scale tests in Europe (7) and the United States (8) have indicated that the V_2O_5 and TiO_2 catalyst may promote the formation of oxidized mercury. The ability to oxidize mercury is largely dependent on the composition of the coal (8).

Lignite and subbituminous coals produce ash that plug and blind catalysts (9–12). The problems currently being experienced on SCR catalysts include the formation of sulfate- and phosphate-based blinding materials on the surface of catalysts and the carrying of deposit fragments, or popcorn ash, from other parts of the boiler and depositing them on top of the SCR catalysts (3). The most significant problem that limits the successful application of SCR catalysts to lignite coal is the formation of low-temperature sodium–calcium–magnesium sulfates, phosphates and, possibly, carbonates on the surfaces of catalysts and the carryover of deposits that will plug the catalyst openings, resulting in increased pressure drop and decreased efficiency (3, 11–14). The degree of the ash-related impacts on SCR catalyst performance depends upon the composition of the coal, the type of firing systems, flue gas temperature, and catalyst design (11, 12, 14, 15).

Licata and others (13) conducted tests on a South African and a German Ruhr Valley coal and found that the German Ruhr Valley coal significantly increased the pressure drop across the catalyst because of the accumulation of ash. They found that the German coal produced a highly adhesive ash consisting of alkali (K and Na) sulfates. In addition, they reported that the alkali elements are in a water-soluble form and highly mobile and will migrate throughout the catalyst material, reducing active sites. The water-soluble form is typical of organically associated alkali elements in coals. The German Ruhr Valley coal has about 9.5% ash and 0.9% S on an as-received basis, and the ash consists mainly of Si (38.9%), Al (23.2%), Fe (11.6%), and Ca (9.7%), with lower levels of K (1.85%) and Na (0.85%) (13). Cichanosicz and Muzio (14) summarized the experience in Japan and Germany and indicated that the alkali elements (K and Na) reduced the acidity of the catalyst sites for total alkali content (K + Na + Ca + Mg) of 8%–15% of the ash in European power plants. Licata et al. also found that alkaline-earth elements such as calcium react with SO_3 on the catalyst, resulting in plugging of pores and a decrease in the ability of NH_3 to bond to catalyst sites. The levels of calcium in the coals that caused blinding ranged from 3% to 5% of the ash. Studies conducted on the impact of alkali elements associated with biomass found that, when biomass is fired, poisoning and blinding of SCR catalysts occurred (16, 17).

This study took a three-pronged approach to solve the issues involving low-rank fuels and the SCR catalyst. Studies were conducted at both the pilot and bench scales and were compared to a thermodynamic equilibrium model. In order to facilitate the pilot-scale study, two slipstream SCR systems were constructed. The slipstream reactors were installed at three power plants. Two of the plants were cyclone-fired: one with lignite and one with subbituminous coal. The third plant was a pulverized-coal (pc), tangentially fired unit using subbituminous coal. The slipstream reactors were designed to expose SCR catalysts to flue gas and particulate matter under conditions that simulate gas velocities, temperatures, and NH_3 injection of a full-scale pilot plant. The control system maintains catalyst temperature, pulse air to remove accumulated deposits, and a constant gas flow across the catalyst; it logs pressure drops and temperatures. The reactor was operated in an automated mode and could be remotely controlled via modem. Testing at each power plant was conducted over 6 months. The reactor was inspected and cleaned at 2-month intervals, and a catalyst section was removed for analysis. The catalysts and associated ash deposits were analyzed to determine the characteristics of the ash on the surface and in the pores. In addition, mercury speciation in the flue gas upstream and downstream of the catalyst was conducted at 2-month intervals during the testing at the lignite-fired plant. The ability of the SCR catalyst to catalyze gaseous elemental mercury (Hg^0[g]) to more soluble and chemically reactive $Hg^{2+}X$(g) forms was evaluated, along with the potential increase in particle-associated mercury (Hg[p]). Increasing the oxidized and particulate fractions of mercury has the potential to increase the efficiency of mercury capture by conventional control devices such as wet flue gas desulfurization scrubbers and electrostatic precipitators.

EXPERIMENTAL

Thermochemical Equilibrium Modeling

The Facility for the Analysis of Chemical Thermodynamics (FACT) is a digital thermodynamic equilibrium model that assesses fuel quality effects on ash behavior in a boiler. It predicts molar fractions (partial pressures) of all gas, liquid, and solid stable components in a system by using the principle of Gibbs free energy minimization. FACT output includes quantities, compositions, and viscosities of liquid and solid mineral phases; the model accurately predicts the behavior of fuel ash, including biomass-derived ash, for different boiler temperature regimes.

In this study, the bulk ash composition and the atmosphere used in the thermogravimetric analyzer (TGA) testing were input to the FACT model. In this model, each reaction is considered independent of all other reactions. For example, the FACT model may predict that species X will dominate while the empirical results show that species Y tends to form (i.e., selectivity and kinetics are not considered by the model).

Bench-Scale TGA Study

Fuels were first combusted in the EERC's conversion and environmental process simulator. Ash resulting from the combustion of these fuels was collected and size-fractionated. Tests were carried out on the size-fractionated ash in a TGA under atmospheric conditions that mimic a combustion environment. The simulated flue gas atmosphere consisted of CO_2, SO_2, NH_3, N_2, O_2, H_2O, and P_2O_5. The flue gas makeup is presented in Table 1. The weight gain of the ash or ash–catalyst mixtures was measured as a function of time and temperature. The tests were conducted at 316°, 371°, and 427°C (600°, 700°, and 800°F). The resulting mixtures were analyzed to determine the influence of SCR catalysts on ash behavior.

Table 1. Flue Gas Makeup

N_2	74%
H_2O	8%
CO_2	14%
O_2	4%
NH_3	100–300 ppm
SO_2	0.04%
P	1–1000 ppm

Slipstream Reactor Installation and Operation

Upon installation at each utility boiler unit, flue gas temperature, composition, and velocity measurements were obtained using portable equipment. Shakedown testing of the unit was conducted to ensure that all components were operating properly and that data were being logged and could be retrieved. After installation and shakedown were completed, the reactor was operated in a computer-controlled, automated mode and monitored on a daily basis to ensure proper operation and data quality. During operation of the SCR slipstream system, catalyst temperature, sootblowing frequency, and pressure drop across the catalyst were monitored and logged. Samples of the exposed SCR catalyst and associated deposits were obtained after exposure to flue gas and particulate for 2, 4, and 6 months. The samples of the catalyst were analyzed to determine the components that were bonding and filling pores, resulting in decreased reactivity.

SEM Ash Characterization

The characteristics of the ash that accumulated on the catalyst were examined using scanning electron microscopy (SEM)–x-ray microanalysis and x-ray diffraction (XRD) (18). The samples were either placed on double-stick tape for surface analysis or mounted in epoxy for cross-section analysis. Correlations between the physical and chemical characteristics of any ash deposits on the SCR test section and entrained-ash sample collected at the chamber inlet and the coal inorganic composition will be made to discern mechanisms of SCR blinding. Entrained ash was collected at the Columbia Station only and characterized with respect to composition and size.

Mercury Measurement

At the Coyote Station, the Ontario Hydro (OH) mercury speciation sampling train was used to determine mercury forms across the SCR test section. The OH extractive mercury speciation sampling technique was used to measure potential mercury conversion across the SCR system over a period of several hours after fresh installation of the SCR test chamber and again just prior to removal of SCR catalyst sections.

The procedure used to conduct the mercury speciation sampling was American Society for Testing and Materials Method D6784-02 entitled “Standard Test Method for Elemental, Oxidized, Particle-Bound and Total Mercury in Flue Gas Generated from Coal-Fired Stationary Sources (Ontario Hydro method)” (19).

The OH method follows standard U.S. Environmental Protection Agency (EPA) methods for isokinetic flue gas sampling (EPA Methods 1–3 and EPA Method 5/17). A sample is withdrawn from the flue gas stream isokinetically through the filtration system, which is followed by a series of impingers in an ice bath. Particulate-bound mercury is collected on the filter; Hg^{2+} is collected in impingers containing 1 N potassium chloride solution; and elemental mercury is collected in one impinger containing a 5% nitric acid and 10% peroxide solution and in three impingers containing a solution of 10% sulfuric acid and 4% potassium permanganate. An impinger containing silica gel collects any remaining moisture. The filter media is quartz fiber filters. The filter holder is glass or Teflon-coated. An approximate 2-hour sampling time was used, with a target sample volume of 1 standard cubic meter.

RESULTS AND DISCUSSION

Task 1 – Identification of Test Coals and Utility Host Sites

Three host utility sites were chosen for the installation of the SCR reactors. The utilities were chosen based on their ability to provide all of the necessary support and hardware for the operation of the SCR reactors. The electric utility units selected for testing are shown in Table 2. The plants where the SCR slipstream system was installed included Alliant Energy’s Columbia Station, Dynegy’s Baldwin Station, and Otter Tail Power Company’s Coyote Station.

Table 2 describes the plants, and Table 3 summarizes the characteristics and selection criteria. The selection criteria that were most important to the success of this project were geographic location, a base load plant, and a consistent supply of one fuel for the duration of the study.

Table 2. Description of Power Plants Tested

	Baldwin	Columbia	Coyote
Unit No.	1	2	1
Utility	Dynegy	Alliant	Otter Tail
Boiler Type	Cyclone	T-fired	Cyclone
Fuel type	Antelope – subbituminous	Caballo – subbituminous	Beulah – Zap lignite
Load	Base	Base	Base
Location	Baldwin, IL	Portage, WI	Beulah, ND
MW	600	520	425

Table 3. Key Selection Criteria

Field Test 1 – Columbia Station

- Tangentially fired boiler to show differences in ash partitioning as compared to cyclone-fired systems.
- High-potential-blinding coal in Caballo, which can be burned nearly 100% for the entire test.

Field Test 2 – Baldwin Station

- Plant is cyclone fired.
- Units already are equipped to do slipstream testing.
- Plant currently fires a blend of Antelope coal and tires; plant is willing to fire 100% Antelope.
- High-potential-blinding coal in Antelope.

Field Test 3 – Coyote Station

- Cyclone-fired with lignite.
- High-potential-blinding coal with high alkali and alkaline-earth elements. Coal can have very high sodium content and is known to cause significant low-temperature deposition.

The units tested were selected based on the fuels fired, boiler type, and availability of the unit for sampling. The average composition of the coals fired during the testing is listed in Tables 4 and 5. The subbituminous coals were typically low ash, nominally 4.5%–5.5% with very high levels of calcium in the ash. In comparison, the lignite contains higher levels of ash and lower calcium but higher levels of sodium. The alkali and alkaline-earth elements are primarily associated with the organic matrix of the coal as salts of carboxylic acid groups (18). The portion of the ash-forming components that are associated with the organic matrix of the coal for subbituminous coal ranges from 30% to 60% (18); for the lignite coal, the portion is about 20% to 40%. The remaining ash-forming components consist of mineral grains. For these coals, the percentage organically associated is 29% for the Antelope, 36% for Caballo, and 19% for Beulah. The minerals present in the coals as determined by computer-controlled scanning electron microscopy (CCSEM) analyses are listed in Table 6. The primary minerals present in the subbituminous coals include quartz and various clay minerals with some pyrite and a mineral that is rich in Ca, Al, and P. This mineral has been identified in some coals as crandalite. The primary minerals found in the Beulah coal include clay minerals (kaolinite), pyrite, and quartz.

Task 2 – Bench-Scale Testing and FACT Modeling

Bench-Scale Testing

The goal of the bench-scale testing was to determine the effect catalyst would have on the conversion of SO_2 to SO_3 and the resulting increase in catalyst blinding. Tests were conducted with and without catalyst on the following fuels: Nanticoke Powder River Basin (PRB), Beulah lignite, and Nanticoke PRB and a low-sulfur U.S. (LSUS) bituminous blend.

The results of the study indicate that the addition of the catalyst to the ash and increased temperature increased the rate of weight gain by as much as tenfold. The weight gain can be directly linked to the rate of sulfation. The test results in Figures 1–3 were compiled using the gas concentrations noted in Table 1 minus the NH_3 and phosphorus compounds (baseline tests). Table 7 contains the ash analysis of the coals used in the bench-scale testing. Figure 1 contains the weight gain curves for the Nanticoke PRB test. The rate of weight gain increased as the temperature increased from 316° to 427°C (600° to 800°F).

Figure 2 contains the weight gain curve for the Beulah lignite. Again the weight gain increased as the temperature was increased from 316° to 427°C (600° to 800°F). The rate of weight gain was similar to what was seen with the Nanticoke PRB test.

[2] Oxide concentrations renormalized to an SO_3-free basis.

A blend of the Nanticoke PRB and an LSUS bituminous coal was tested at a 52–48 blend (PRB–LSUS). The weight gain curves for this test are in Figure 3. The results of this experiment are again similar to those obtained in the previous two cases, with the exception of the 427°C (800°F) test. The 427°C (800°F) test in this case gains slightly more weight than the previous two experiments. At high temperatures, this blend had almost double the weight gain from the straight PRB case. This indicates that there is likely more sulfur available from the bituminous coal.

More testing was completed on the Nanticoke PRB and the PRB–LSUS blend. In Figures 4–5, the gas used in the study now contains the NH_3 and phosphorus compounds in addition to the gas used in the previous three tests. Figure 4 contains the data for the Nanticoke PRB test with NH_3 and phosphorus. The addition of the NH_3 and phosphorus compounds increased the rate of weight gain in the 427°C (800°F) test. The difference in rates as temperature was increased became less pronounced.

Figure 5 contains the weight gain curves for the PRB–LSUS test. The rate of weight gain was also increased; however, the temperature effect was still present (increased weight gain with increased temperature).

The baseline tests (without NH_3 and phosphorus compounds) were repeated with the addition of SCR catalyst to the mixture. The results of these tests are in Figures 6–7. Figure 6 contains the weight gain curves for the Nanticoke PRB test with catalyst and the Nanticoke PRB test at baseline conditions and 427°C (800°F). The rate of weight gain with the addition of catalyst at 427°C (800°F) increased approximately 7-fold in this case. The addition of the catalyst will increase the amount of SO_2 that is oxidized to a more reactive form (SO_3), which will in turn increase the rate of sulfate formation.

Figure 7 contains the weight gain curves for the PRB–LSUS blend with catalyst. In this test, the rate of weight gain increased almost tenfold. Again, the increased rate can be attributed to more SO_3 in the system.

FACT Modeling

FACT thermodynamic equilibrium modeling was conducted on each of the ash and flue gas systems tested in the bench-scale screening. The FACT modeling will give an indication of what chemical species are thermodynamically favored at the temperature present in the SCR. Figures 8–13 contain the results of the FACT modeling on the Nanticoke PRB, Beulah lignite, and the Nanticoke PRB–LSUS blend. The gas composition used for the modeling is the same as what was used for the bench-scale analysis in Table 1.

Figures 8–10 have the results for the Nanticoke PRB, Nanticoke PRB–LSUS blend, and the Beulah lignite with 300 ppm NH_3 and 1000 ppm phosphorus pentoxide added. The model predicts that in all three cases the alkali/alkaline-earth phosphates and sulfates will be the predominant species formed. Trace amounts of phosphoric and sulfuric acid will also be present at lower temperatures (232°C [450°F]).

Figures 11–13 have the results for the Nanticoke PRB, the Nanticoke PRB–LSUS blend, and the Beulah lignite with 100 ppm NH_3 and 1 ppm phosphorus pentoxide added. With less phosphorus present, the model predicts that sulfates will dominate. In the case of the Nanticoke PRB, the formation of carbonate compounds is also predicted.

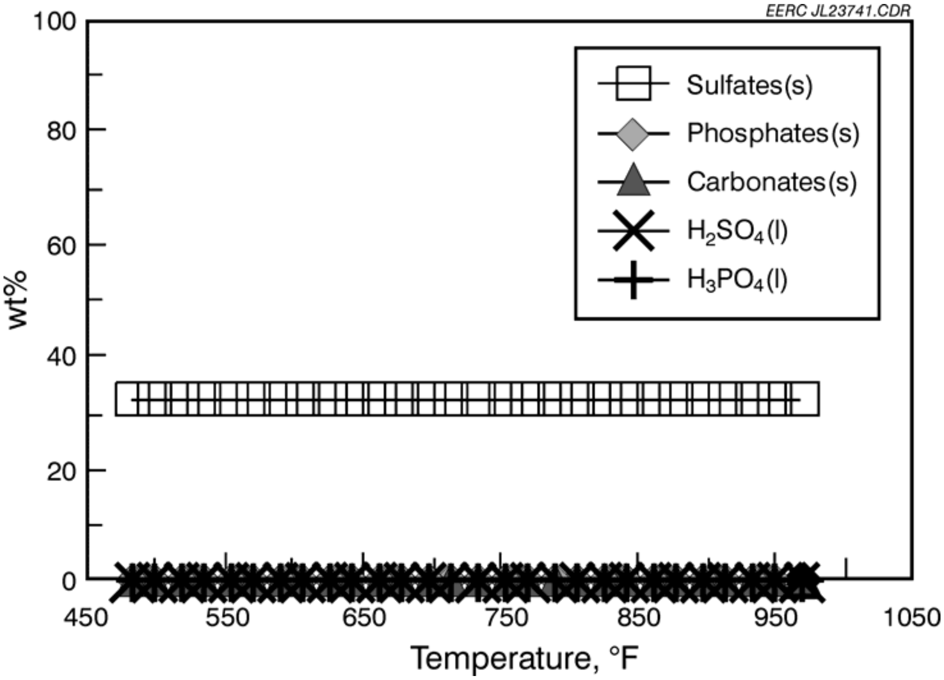

Figure 12. FACT modeling results for Nanticoke PRB–LSUS blend with 100 ppm ammonia and 1 ppm P_2O_5.

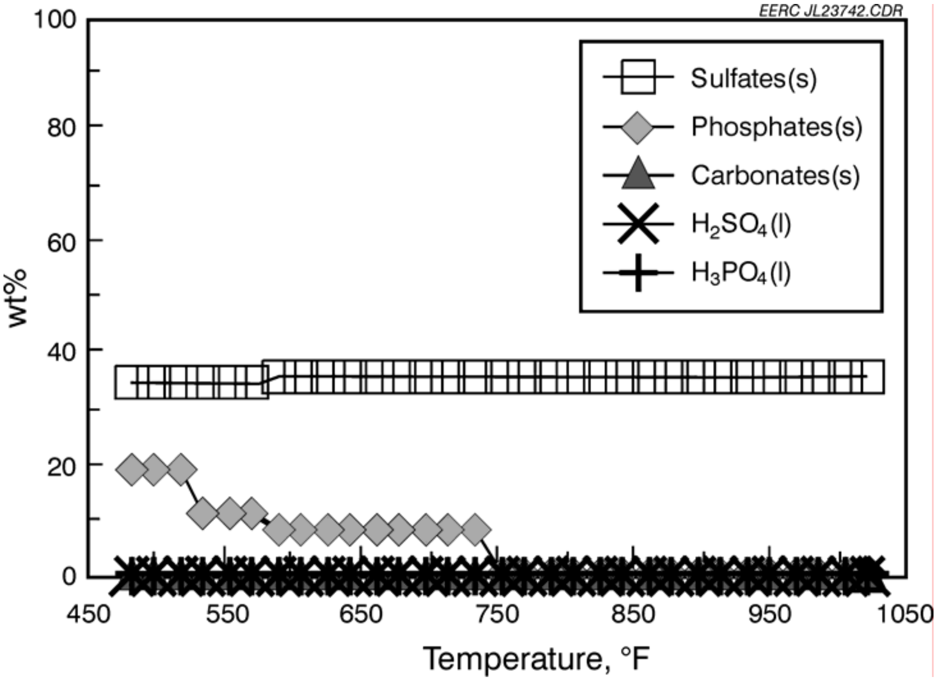

Figure 13. FACT modeling results for Beulah with 100 ppm ammonia and 1 ppm P_2O_5.

Characterization of Reaction Products from Bench-Scale Tests

The reaction products from three of the bench-scale tests were analyzed with SEM to validate the FACT modeling and to determine that the material gained during the tests was indeed a sulfate. Figures 14–16 are SEM micrographs of the fly ash from the Nanticoke PRB, Nanticoke PRB–LSUS blend, and the Beulah lignite. Corresponding Tables 8–10 contain the chemical analysis of several fly ash particles. Sulfur is present in almost all analyses and increases along with calcium. This indicates that most of the sulfur is present as calcium sulfate. These results are also consistent with the FACT modeling predictions. One exception may be that phosphates were not present in large quantities.

Task 3 – Design and Construction of the SCR Slipstream Test Chamber

The SCR slipstream system consists of two primary components: the control room and the SCR reactor. The reactor section consists of a catalyst section, an NH_3 injection system, and sampling ports for NO_x at the inlet and exit of the catalyst section. The control room houses a computer system that logs data and controls the gas flow rates, temperatures, pressure drop across the catalyst, and sootblowing cycles. The computer was programmed to maintain constant temperature of the catalyst, gas flow rates, sootblowing cycles, and NH_3 injection. The computer is equipped with a modem that allowed for downloading of data and modification of the operation of the reactor from a remote computer located at the EERC.

A schematic diagram of the SCR slipstream system is shown in Figure 17. Flue gas is isokinetically extracted from the convective pass of the boiler upstream of the air heater. The temperature is typically about 790°F. The flue gases pass through a 4-inch pipe equipped with sampling, thermocouple, and pressure ports. NH_3 is injected into the piping upstream of the reactor section. The reactor consists of a steel housing that is approximately 8.5 inches square and 8 feet long. The reactor section illustrated in Figure 18 has three components, including a flow straightener, a pulse section or sootblower, and a catalyst test section. A metal honeycomb is used as a flow straightener upstream of the catalyst section and is about 6 inches long. A purge section was installed ahead of the catalyst test section to remove accumulated dust and deposits. The catalyst test section is located downstream of the purge section. The entire catalyst section is insulated and equipped with strip heaters for temperature control. The catalyst test section is 1 m (3.28 ft) in length and houses three catalyst sections. Thermocouple and pressure taps are located in the purge sections for measurements before and after each section.

The induced-draft fan is used to extract approximately 5.6 scmm (200 scfm) of flue gas from the convective pass of the utility boiler to achieve an approach velocity of 5.2 m/s (17.0 ft/s). The total gas flow through the reactor represents a thermal load of approximately 300 kW.

The range of operating conditions for the reactor is listed below:

- Gas temperature: ~371°–426°C (700°–800°F)
- Gas flow rate: 11.3–14.2 acmm (400–500 acfm)
- Approach velocity range: 5.0–5.5 m/sec (16.4–18 ft/s)

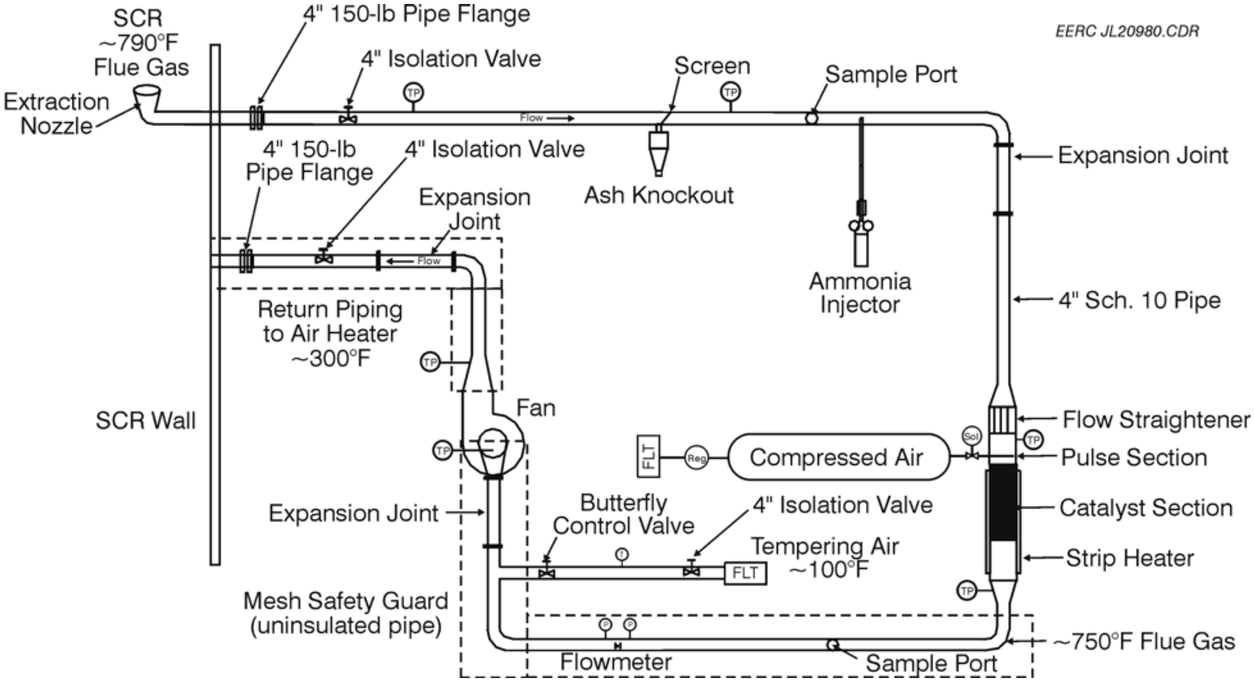

Figure 17. Conceptual schematic of the SCR reactor slipstream field test unit.

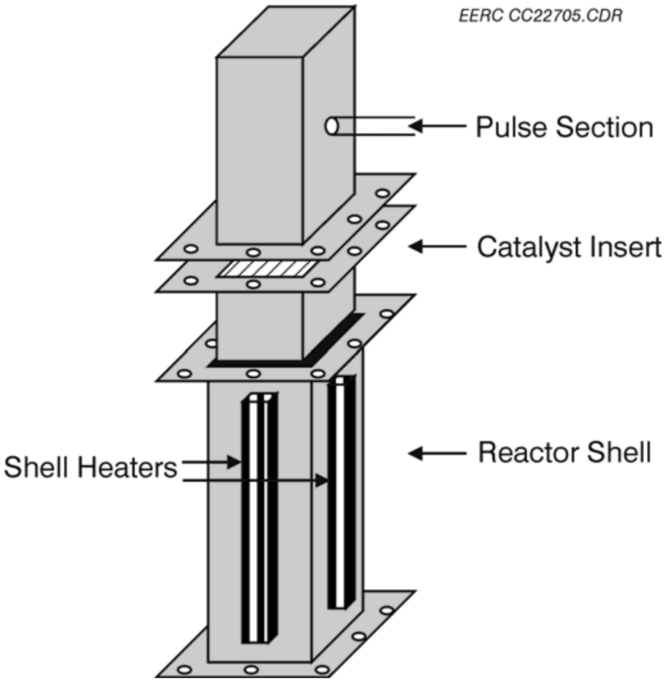

Figure 18. SCR catalyst section.

- NH_3 injection rate: 0.5:1 with NO_x level
- Tempering air for fan: ~1.4–5.7 scmm (50–200 scfm)
- Catalyst dP: 0.5–1.0 inches water column
- Fan sized for up to 30 inches water column

For catalyst inspection or replacement, the catalyst section can be unbolted and slid out from the reactor (support brackets hold the remaining reactor pieces in place). Once a catalyst reactor section is removed, the top catalyst holder can be removed, and the section(s) of interest removed by pushing it up from the bottom and out the top. A new section is then inserted from the top to replace the piece removed.

Task 4 – SCR Test Chamber Installation and Data Collection at Utility Host Sites

The catalyst installed at the Baldwin and Coyote Stations was the Haldor Topsoe catalyst. Topsoe's DNX-series of catalysts comprises SCR DENOX catalysts tailored to suit a comprehensive range of process requirements. DNX-series catalysts are based on a corrugated, fiber-reinforced TiO_2 carrier impregnated with the active components V_2O_5 and tungsten trioxide (WO_3). The catalyst is shaped to a monolithic structure with a large number of parallel channels. The unique catalyst design provides a highly porous structure with a large surface area and an ensuing large number of active sites. Figure 19 is an image of the Haldor Topsoe SCR catalyst. The pitch of the catalyst was approximately 6 mm.

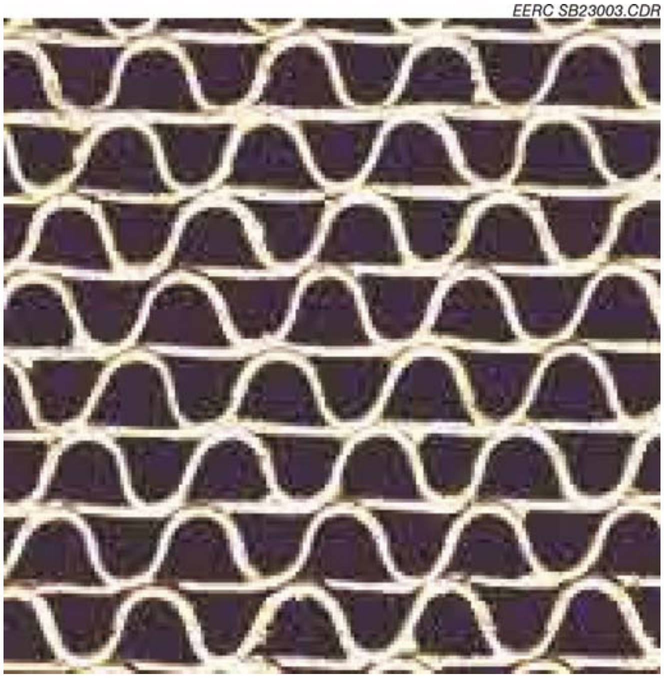

Figure 19. Haldor Topsoe SCR catalyst showing the gas flow passages.

The catalyst installed at the Columbia Station was a Babcock Hitachi plate-type catalyst. This catalyst is a TiO_2-based plate catalyst, developed and manufactured by Hitachi. Figure 20 shows the design of the catalyst. The pitch of the catalyst was approximately 10 mm.

Upon installation at each utility boiler unit, flue gas temperature, composition, and velocity measurements were obtained using portable equipment. Shakedown testing of the unit was conducted to ensure that all components were operating properly and that data were being logged and could be retrieved. After installation and shakedown were completed, the reactor was operated in a computer-controlled, automated mode and monitored on a daily basis to ensure proper operation and data quality. During operation of the SCR slipstream system, catalyst temperature, sootblowing frequency, and pressure drop across the catalyst were monitored and logged. Samples of the exposed SCR catalyst and associated deposits were obtained after exposure to flue gas and particulate for 2, 4, and 6 months. The samples of the catalyst were analyzed to determine the components that were bonding and filling pores, resulting in decreased reactivity.

The characteristics of ash that accumulated on the catalyst were examined using SEM–x-ray microanalysis and XRD (18). Correlations between the physical and chemical characteristics of any ash deposits on the SCR test section and entrained-ash sample collected at the chamber inlet and the coal inorganic composition were made to discern mechanisms of SCR blinding. Entrained ash was collected at Columbia Station only and characterized as to composition and size.

Baldwin Station Data

The data presented in the following section represent a small portion of the operational data collected. The remainder of the data is available upon request. The reactor was installed at the Baldwin Station and operated for a 6-month time period on the Haldor Topsoe catalyst. The information obtained from testing included pressure drop, sootblowing cycles, and reactor temperatures. Table 11 summarizes the operating conditions of the reactors during the testing periods at all plants. Figures 21–23 show the pressure drop across the catalyst test periods from 0 to 2 months, 2 to 4 months, and 4 to 6 months, respectively. During the first 2 months of operation, the pressure shown in Figure 21 was about 0.5 inches of water; at the end of 2 months, the pressure drop was about 0.8 inches of water, indicating plugging had occurred. The air was pulsed a minimum of every 8 hours in an attempt to maintain cleanliness. The reactor was monitored on a daily basis, and adjustments in pulsing cycles were made in order to minimize deposit accumulation. However, for the first 2 months, the pressure drop steadily increased. During several periods when the unit was taken off-line, the temperature of the catalyst was maintained. At 2-month intervals, a section of catalyst was removed and replaced with a new one.

For Months 2 through 4, the pressure drop was highly variable initially but was about 0.8 inches of water. From Months 4 through 6, the pressure drop was maintained between 0.6 and 0.8 inches of water. This is due to the installation of a fresh catalyst section and leaving two-thirds of the catalysts in place that were partially plugged. The gas velocity in the single section of new, clean catalyst was high because of channeling, and the result of the high gas flow was less deposition and accumulation. Gas velocity has a significant impact on the potential for deposits to form. However, at high gas velocity, low NO_x conversion is likely.

Columbia Station Data

The reactor was installed at the Columbia Station and operated for a 6-month period of time for the Babcock Hitachi catalyst. The information obtained from the testing included pressure drop information, sootblowing cycles, and reactor temperature. Table 11 shows the reactor temperature, air-pulsing cycles, and airflow rates. Figures 24–26 show the test periods from 0 to 2 months, 2 to 4 months, and 4 to 6 months, respectively. The pressure drop across the SCR upon installation was about 0.4 inches of water and increased to an average of about 0.5 inches of water, but ranged from less than 0.4 to greater than 0.8 inches of water. Figure 25

Table 11. Selected Operating Conditions of the SCR Catalysts

Plant Name	Average SCR Inlet Temp., °F	Average SCR Outlet Temp., °F	Air Pulse Frequency	Flue Gas Flow Rate, acfm
Baldwin	645	549	Once a day and on demand	393
Columbia	672	662	Once a day and on demand	385
Coyote	675	667	Once a day and on demand	385

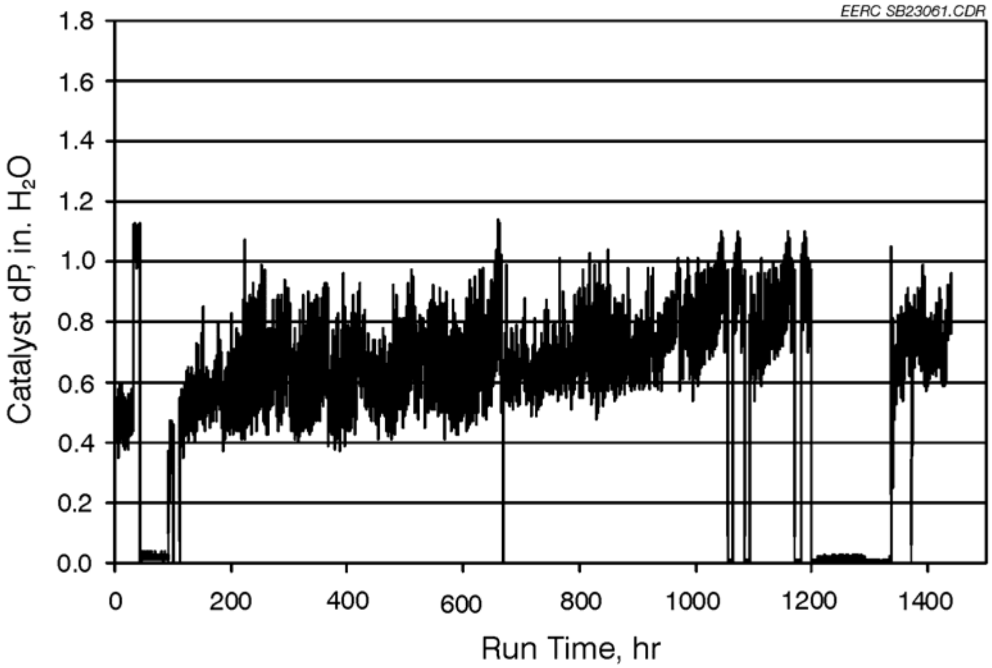

Figure 21. Catalyst pressure drop at Baldwin Station at 0 to 2 months of operation.

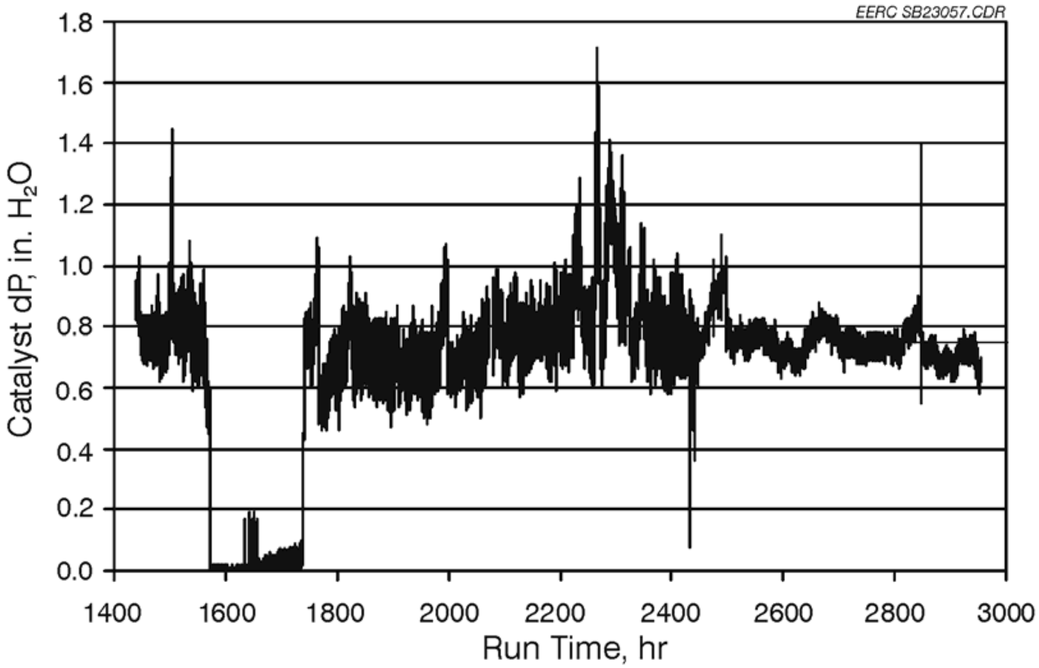

Figure 22. Catalyst pressure drop at Baldwin Station at 2 to 4 months of operation.

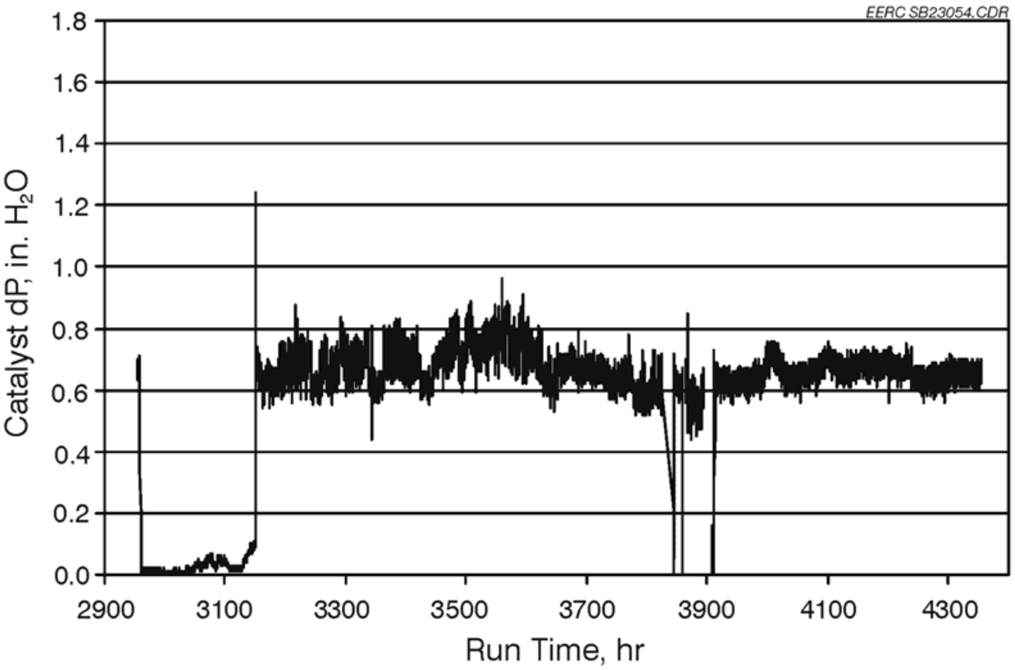

Figure 23. Catalyst pressure drop at Baldwin Station at 4 to 6 months of operation.

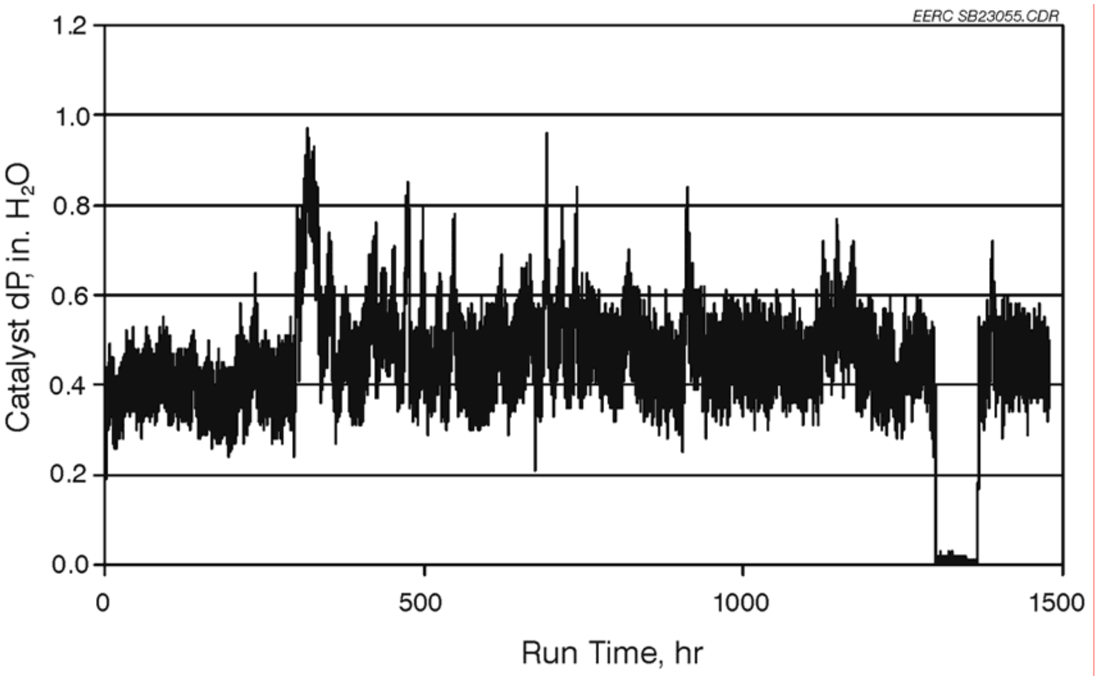

Figure 24. Catalyst pressure drop at Columbia Station at 0 to 2 months of operation.

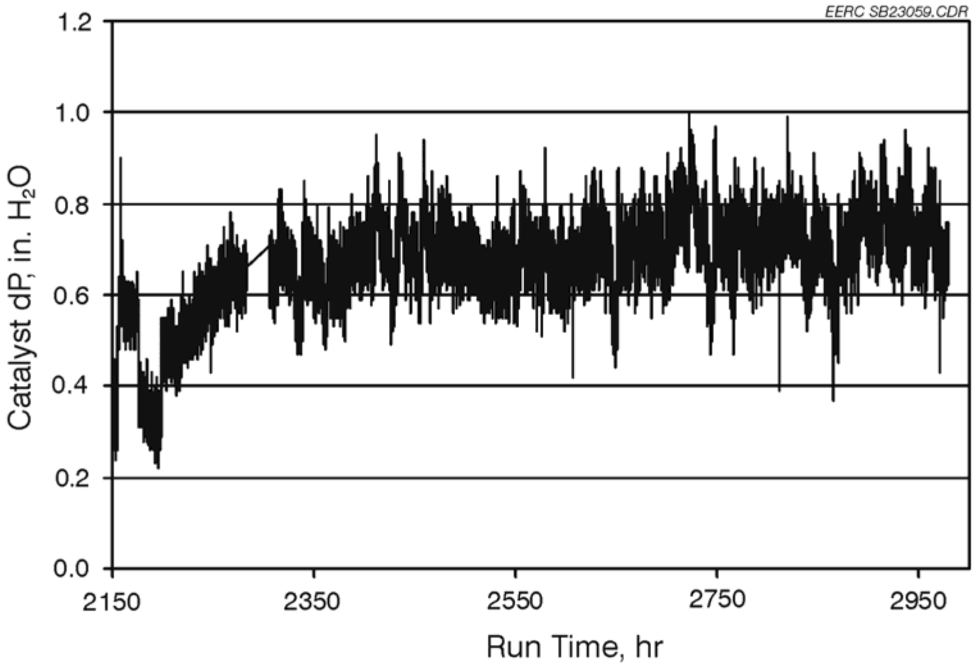

Figure 25. Catalyst pressure drop at Columbia Station at 2 to 4 months of operation.

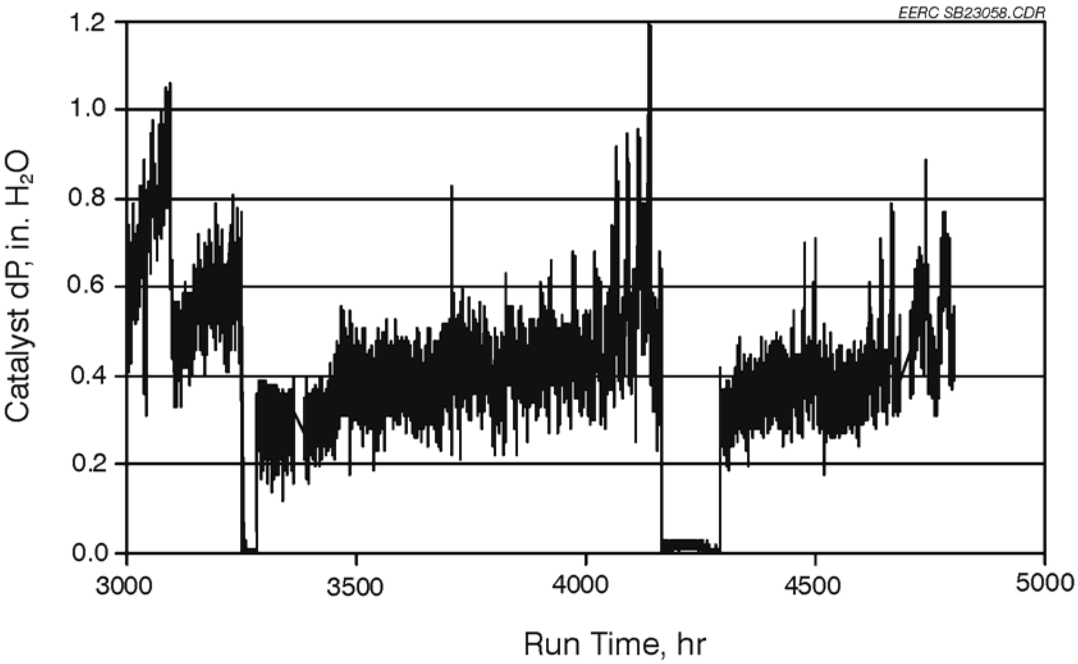

Figure 26. Catalyst pressure drop at Columbia Station at 4 to 6 months of operation.

shows the pressure drop for Months 2–4. The pressure drop increased from about 0.5–0.7 inches of water because of accumulation of ash. Figure 26 shows a rapid increase in pressure drop across the catalyst at about 3000 hours of operation, and aggressive pulsing brought it down to 0.4 inches of water until the catalyst section was changed out at about 3200 hours. After the reactor was cleaned and one catalyst section was replaced, the pressure drop was about 0.3 but increased to over 0.6 inches of water up to about 4100 hours. There was an outage at the plant, and aggressive pulsing of the reactor was conducted; the pressure drop was brought back down to 0.3 but rapidly increased to over 0.5 inches of water within 500 hours.

Coyote Station Data

The same reactor that was installed at the Baldwin Station was moved and installed at the Coyote Station. In addition, the same Haldor Topsoe catalyst formulation was used in the reactor. The cleaning cycles, temperatures, and gas flow rates are listed in Table 11. The reactor was operated for 6 months. Figures 27–29 show the test periods from 0 to 2 months, 2 to 4 months, and 4 to 6 months, respectively. The pressure drop across the catalyst upon installation was about 0.4 inches of water. After only 750 hours, the pressure drop was 1.5 inches of water, indicating significant plugging and blinding. Aggressive air pulsing was conducted, with little success in removing the deposits. The pressure drop for the catalyst was over two times greater than the pressure drop observed for the Baldwin Station utilizing the same reactor and the same catalyst. At about 1700 hours, the reactor was cleaned, and a section of catalyst was removed for characterization. The pressure drop after cleaning was 0.8–1.0 inches of water. The pressure drop did not increase as rapidly because of the higher velocities through the clean section of the catalyst. Figure 29 shows the pressure drop for 4–6 months of operation. The pressure drop

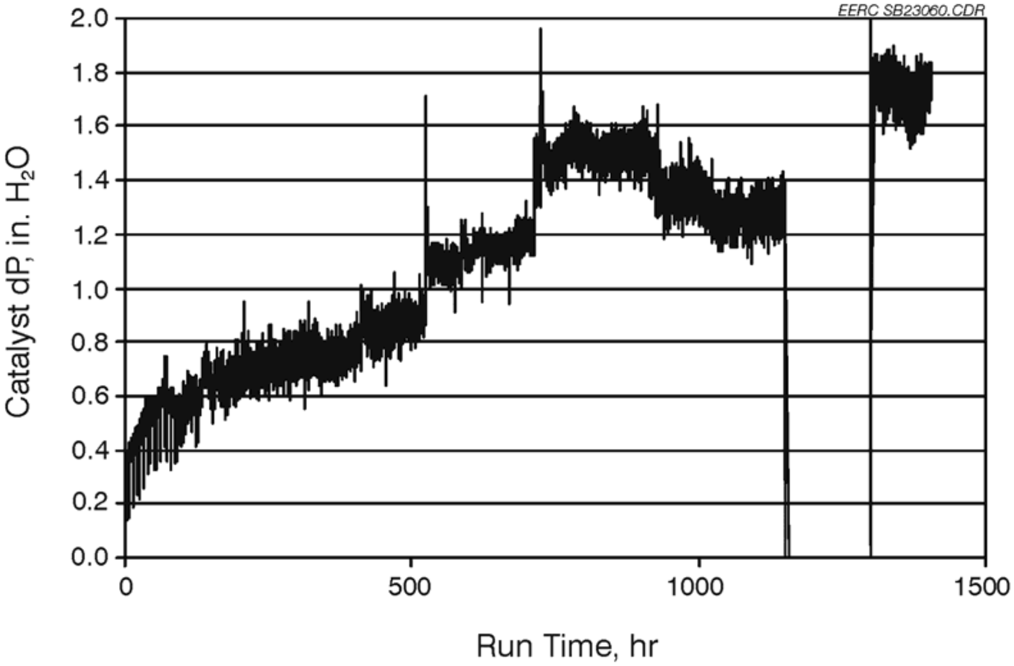

Figure 27. Catalyst pressure drop at Coyote Station at 0 to 2 months of operation.

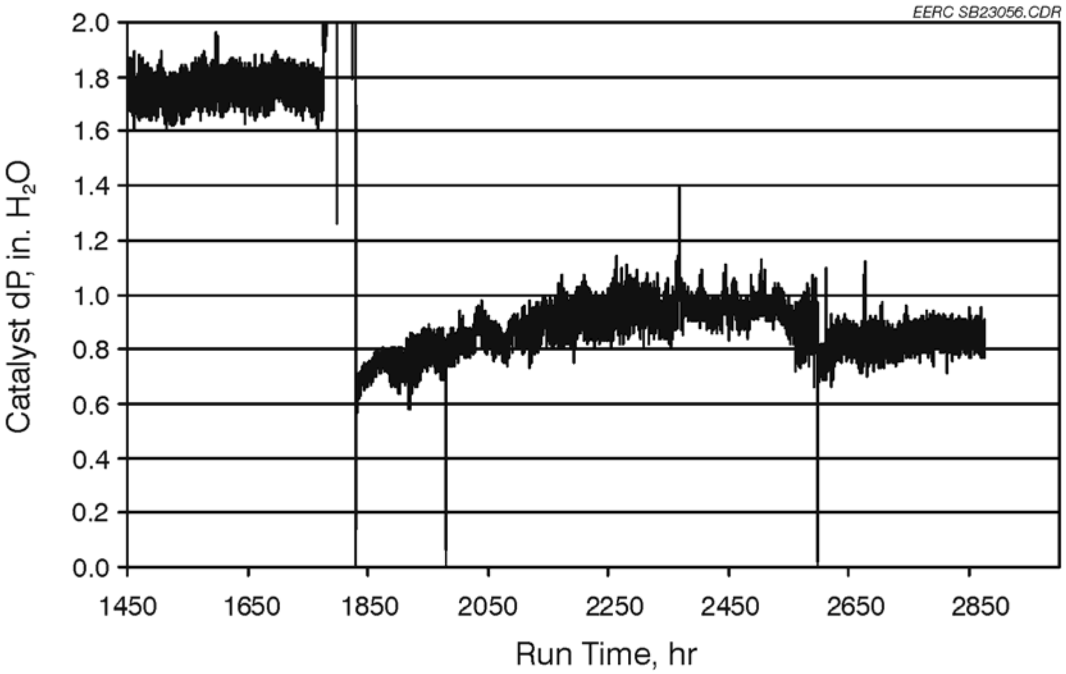

Figure 28. Catalyst pressure drop at Coyote Station at 2 to 4 months of operation.

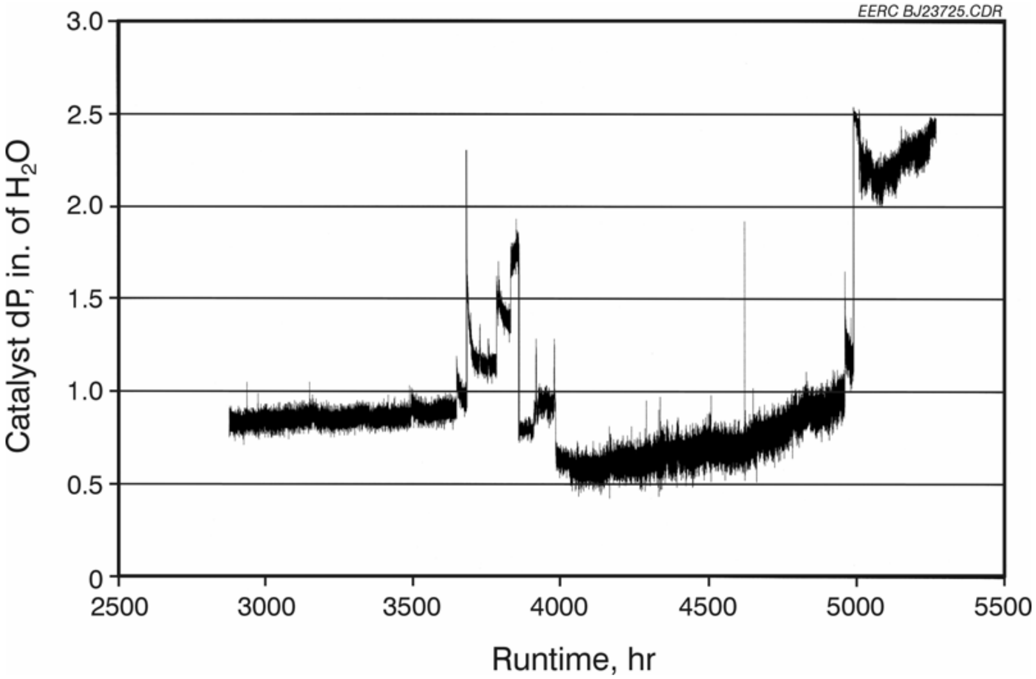

Figure 29. Catalyst pressure drop at Coyote Station at 4 to 6 months of operation.

during the last 2 months of testing was highly variable and at times reached values over 2 inches of water.

Visual Observations and Chemical Analysis

The tops of the catalysts were photographed during inspection and sampling of the catalyst sections. Figure 30 shows the ash materials that accumulated on the catalyst inlet after 2 months of operation. The most significant accumulation was noted for the Coyote Station, followed by Columbia and Baldwin. The Coyote Station had some larger pieces of ash deposit material on the surface as well as plugging of the catalyst passages. The Baldwin Station showed some obvious deposition along the walls of the reactor and some accumulation on the inlet sections. The Columbia Station showed more significant accumulation and plugging than the Baldwin Station. After 4 months, the tops of the catalysts were photographed during inspection and sampling of the catalyst sections, as shown in Figure 31. The most significant accumulation was noted for the Coyote Station and some accumulation for the Baldwin Station.

The ash materials that collected on the catalyst surfaces and pores were characterized by SEM and x-ray microanalysis, and in selected cases, XRD was used to determine the crystalline phases present. The catalysts were sampled after 2, 4, and 6 months. The sections were sampled, and approximately 2.5-cm squares were mounted for SEM analysis on double-stick tape and in epoxy resin. The double-stick tape samples allowed for characterization of the external morphology of the particles and catalyst surface. The samples mounted in resin were cross-sectioned and polished, which allowed for more detailed and quantitative analysis of the bonding materials and materials that accumulated in the pores of the catalyst. The data presented in the following section represent a small portion of the data collected by SEM analysis. The remainder of the data is available upon request.

Baldwin Station Deposits

Samples of catalyst were removed from the Baldwin Station after exposure to flue gas and particulate after 2, 4, and 6 months. Figure 32 shows the characteristics of the ash deposit material on the SCR catalyst after 2 months of exposure. This is a polished cross section of a deposit on the surface of the catalyst. Figure 32a shows particles on the surface of the catalyst that range in size from <1 to 15 µm. The larger particles range from oxides of solely silicon and iron to complex mixtures rich in aluminum and calcium; aluminum, silicon, and calcium; aluminum, calcium, and iron; and sodium, calcium, aluminum, and silicon. Chemical analysis of selected particles is summarized in Table 12. The samples of ash mounted on double-stick tape allow for the characterization of the external surfaces of the particles. The surface of a typical particle that is accumulating on the surface of the catalyst is shown in Figure 32b. The blebs on the surface are composed of calcium and sulfur, with some iron and minor amounts of sodium and potassium. Figure 32c shows a cross section of the deposited particles showing calcium- and aluminum-rich particles bonded together with a calcium- and sulfur-rich phase. This phase is in the form of calcium sulfate based on XRD analysis conducted on the deposited ash samples.

The 4-month sample from the Baldwin Station showed more extensive sulfation of the alkaline-earth elements present in the deposits. Figure 33 shows the images of a polished cross

section of an ash deposit on the surface of the catalyst. The deposit formed both on the surface of the catalyst and within the catalyst pores, as shown in Figure 33a. Figure 33b shows a higher-magnification view of the deposit on the catalyst surface. The deposit consists of particles of fly ash bonded together by a matrix of calcium- and sulfur-rich material, likely in the form of calcium sulfate. The chemical composition of selected points shown in Table 13 shows high levels of calcium and sulfur. There is much more extensive bonding of the materials with the sulfate matrix as compared to the 2-month sample.

The 6-month sample from the Baldwin Station showed extensive sulfation of the alkaline-earth elements present in the deposits. Figures 34a and 34b show regions of the catalyst where all the pores were blocked and a minimal amount of deposit on the surface of the catalyst. Figure 34c shows a higher-magnification view of the deposit that is filling the catalyst pore. The deposit consists of particles of fly ash bonded together by a matrix of calcium- and sulfur-rich material, likely in the form of calcium sulfate. The chemical compositions of selected points that

indicate the presence of high levels of calcium and sulfur are listed in Table 14. There is much more extensive bonding of the materials with the sulfate matrix as compared to the 2-month sample. In addition, there are some regions of high levels of calcium, aluminum, and sulfur present. The calcium aluminum materials are likely derived from the calcium aluminum phosphate minerals found in the coal fired at this plant.

Columbia Station Deposits

The 2-month sample from the Columbia Station showed particles adhering to the surface and filling pores in the catalyst, as shown in Figure 35. Figure 35a shows the external morphology of the catalyst surface showing particles trapped in the pores of the catalysts. Chemical compositions of selected points are shown in Table 15. The 2-month sample shows significant evidence of sulfation after only 2 months of exposure. It appears to be more

compositions of selected points are shown in Table 18. The 2-month sample shows significant evidence of sulfation after only 2 months of exposure and was much more pronounced than the 2-month samples for the Baldwin and Columbia Stations that are fired on PRB coals. Figures 38b and 38c show a higher-magnification view of the deposit that is filling the catalyst pores. The deposit consists of particles of fly ash bonded together by a matrix of calcium- and sulfur-rich material, likely in the form of calcium sulfate. The presence of sodium enhances the bonding and sulfation of the particles to form a strongly bonded matrix.

The 4-month sample from the Coyote Station showed particles adhering to the surface and completely filling and masking the pores in the catalyst as shown in Figure 39. Figure 39a shows the external morphology of the catalyst surface showing the masking of the catalyst surface. Chemical compositions of selected points are shown in Table 19. The 4-month sample shows more sulfation than the 2 months of exposure samples. Figures 39b and 39c show a higher-magnification view of the deposit that is filling the catalyst pores. The deposit consists of

Reactivity Testing

Samples of the catalyst from 2, 4, and 6 months of operations were submitted to the appropriate catalyst vendor for reactivity testing. The results of only the samples from the Baldwin installation are available at the time of this report. An addendum to this report will be sent when the results from Coyote and Columbia are made available to the EERC.

Table 21 contains the results of the reactivity analysis on the 2-, 4-, and 6-month samples from the Baldwin Station. After 2 months of operation, the catalyst had no noticeable loss of reactivity when compared to the reference catalyst. After 4 months, the reactivity was 96% of the reference, and after 6 months, the reactivity had dropped to 84% of the reference catalyst.

Task 5 – Determination of SCR Blinding Mechanisms

The mechanism for the formation of deposits that blind SCR catalysts involves the transport of very small particles rich in alkali and alkaline-earth elements, the surface of the catalyst, and reactions with SO_2/SO_3 to form sulfates. The formation of SO_3 from SO_2 is catalyzed by the SCR; this, in turn, increases the reaction rate of SO_3 to form sulfates. In some cases, the alkali and alkaline-earth elements will also react with CO_2 to form carbonates. XRD analysis shown in Figure 41 identified $CaSO_4$ as a major phase and $Ca_3Mg(SiO_4)_2$ and $CaCO_3$ as minor phases.

Lignite and subbituminous coals contain high levels of organically associated alkali and alkaline-earth elements, including sodium, magnesium, calcium, and potassium, in addition to mineral phases. The primary minerals present in these coals include quartz, clay minerals, carbonates, sulfates, sulfides, and phosphorus-containing minerals (18).

During combustion, the inorganic components in the coal are partitioned into various size fractions based on the type of inorganic component, their association in the coal, and combustion system design and operating conditions. Significant research has been conducted on ash formation mechanisms and relationships and their resulting impacts on power plant performance (18–34). Typically, during combustion the inorganic components associated with western subbituminous and lignite coal are distributed into various size fractions of ash, as shown in Figure 42. The results shown in Figure 42 were obtained from isokinetic sampling, aerodynamically size-fractionating ash particles from a full-scale pc-fired boiler firing subbituminous coal, and analyzing each size fraction. The results show that the smaller-sized fractions of ash are dominated by partially sulfated alkali and alkaline-earth elements. These ash particles are largely derived from the organically associated cations in the coal. The larger-sized fraction has higher levels of aluminum and silicon derived from the mineral fraction of the ash-forming component of the coal.

Entrained ash was extracted from the Columbia Station at the point of the inlet to the SCR reactor and was aerodynamically classified and analyzed. The composition of the size fractions was compared to the chemical composition of the ash deposited on and in the catalyst, as shown in Figure 43. The comparison shows that the composition of the particle captured in the SCR catalyst is very similar to the <5-µm size fraction. The deposited material shows significantly more sulfation than the entrained-ash size fraction, indicating that the sulfation process occurs after the particles are deposited in the catalyst.

The mechanism of SCR catalyst blinding when lignite or subbituminous coals are fired is shown in Figure 44 (35). The requirements for the formation of deposits that blind SCR catalyst include firing a coal that produces significant levels of <5-µm-sized particles. The particles are transported into the pores of the catalyst and subsequently react with SO_3 to form sulfates. The sulfate forms a matrix that bonds other ash particles. The SCR catalyzes the formation of SO_3 and thereby increases the rate of sulfation (9, 15). The sulfation of CaO increases the molar

volume, resulting in the filling of the pore. For coals that have high sodium contents, formation of low melting point phases such as pyrosulfates are possible (36). Pyrosulfate materials can melt at temperatures as low as 279°C (535°F) in coal-fired power systems.

Add-On Task – Characterization of Mercury Transformations Across SCR Catalysts for a Lignite Coal-Fired Boiler

The ability of mercury to be oxidized across the SCR catalyst was investigated at the Coyote Station. The Coyote Station is fired on North Dakota lignite, and the flue gas is dominated by elemental mercury. Measurement of mercury speciation was conducted using the OH method at the inlet and the outlet of the SCR catalyst. The measurements were made upon installation of the catalyst and after 2 and 4 months of operation. The results of the mercury speciation measurement at the inlet and outlet of the SCR catalyst conducted upon installation are shown in Figure 45. The inlet and outlet measurements were repeated three times and are shown in Figure 45. The level of elemental mercury at the inlet was approximately 76% to 92%, with the remaining in the oxidized form ranging from 8% to 24%. Very little was in the form of particulate mercury at the inlet. Measurement of mercury speciation was conducted with the NH_3 on and off. The results with the NH_3 off showed an increase in the oxidized mercury to 43% of the total mercury occurring across the SCR catalyst. However, when the NH_3 was introduced into the SCR catalyst, the amount of mercury oxidation decreased from 43% to 19%. There was an increase in the particulate mercury from 1.0% to 7.2%.

The mercury oxidation after the SCR catalyst was exposed to flue gas and particulate for 2 months is shown in Figure 46. The level of oxidized mercury at the inlet ranges from 7.5% to 11.1% of the total mercury. The level of oxidized mercury at the outlet ranged from 7.6% to 14% of the total mercury. The level of particulate mercury increased from a negligible level to 3% of the total mercury at the outlet.

The results of mercury oxidation across the SCR catalyst after 4 months of exposure to flue gas and particulate are shown in Figure 47. The results show a higher level of oxidized mercury at the inlet as compared to testing conducted at installation and after 2 months. The level of oxidized mercury at the inlet ranges from 32% to 38% of the total, with about 5% of the total in the particulate form. The outlet levels of oxidized mercury decrease after passing through the catalyst to about 20% of the total. The level of particulate mercury remained about the same across the catalyst.

The results of mercury oxidation across the SCR catalyst after 6 months of exposure to flue gas are shown in Figure 48. The amount of oxidized mercury at the inlet ranges from 6.5% to 10.5% of the total with about 2.0% in the particulate form. The levels of oxidized mercury at the outlet increases slightly to 8.5% to 11.0% of the total mercury, while the particulate bound mercury also increases to as high as 12.0%.

Task 6 – Final Interpretation, Recommendations, and Reporting

Lignite and subbituminous coals contain high levels of organically bound alkali and alkaline-earth elements, including sodium, calcium, potassium, and magnesium. During combustion, partitioning of these elements occurs based on the size of particles, their association in the coal, and system configuration. This phenomenon, coupled with the fact that SCR catalyst

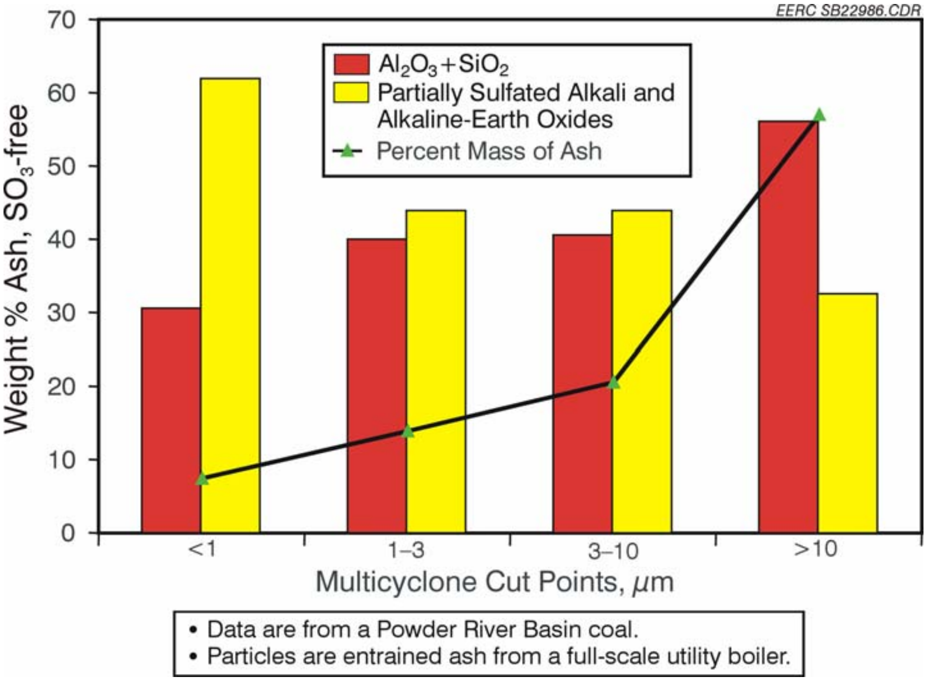

Figure 42. Simplified illustration of ash partitioning in combustion systems (18).

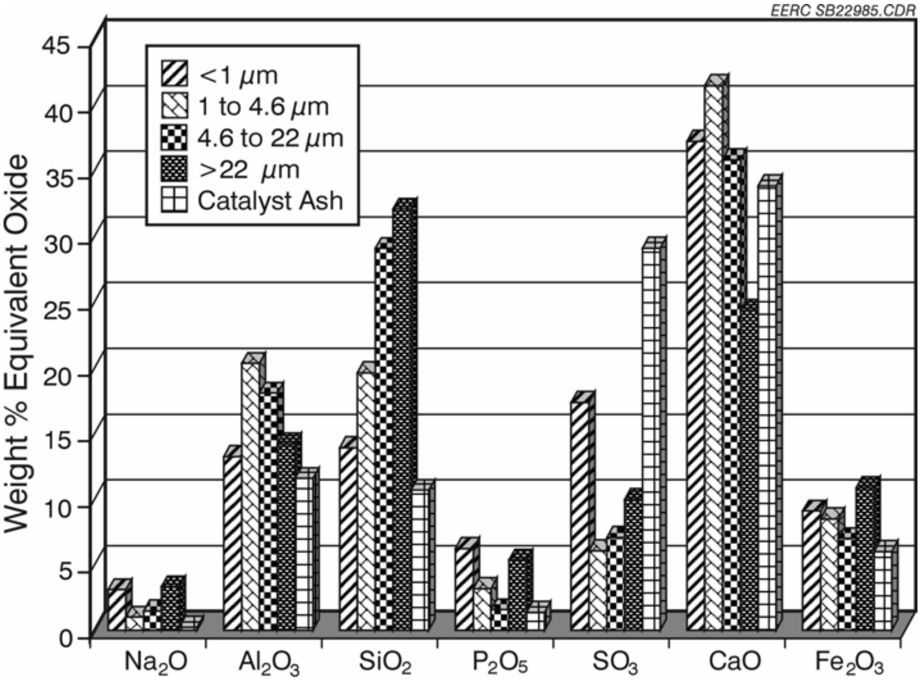

Figure 43. Comparison of entrained ash and deposited ash on catalyst for Columbia Station.

increases the oxidation of SO_2 to SO_3, will lead to extensive blinding of SCR catalyst by the formation of alkali or alkaline-earth sulfates. The results of this study lead the authors to suggest careful evaluation of each SCR installation on applications using subbituminous coals and suggest no installations of SCRs on plants firing lignite coal until further evaluations or improvements to the current technology can be carried out. Installations involving lignite fuels will need advanced cleaning techniques to handle the high-sodium and high-dust loads associated with burning most lignite fuels. The presence of SCR catalyst did not enhance mercury oxidation in the lignite-fired combustion system tested in this study.

CONCLUSIONS

The EERC evaluated the effects that ash from lignite- and PRB-fired combustion has on the performance of SCR catalyst. In order to conduct these tests, a slipstream reactor was designed to expose the SCR catalyst to coal combustion-derived flue gases and particulates. The system is computer-controlled and operates in an automated mode. The system can be operated and monitored remotely through a modem connection. SCR catalyst testing was conducted at two subbituminous-fired plants and one lignite-fired plant. The boiler configurations for the subbituminous-fired plants included a cyclone- and a tangentially fired boiler. The lignite plant was cyclone-fired.

The pressure drop across the catalyst was found to be the most significant for the lignite-fired plant as compared to the subbituminous-fired plants. Both coals had significant accumulations of ash on the catalyst, on both macroscopic and microscopic levels. On a

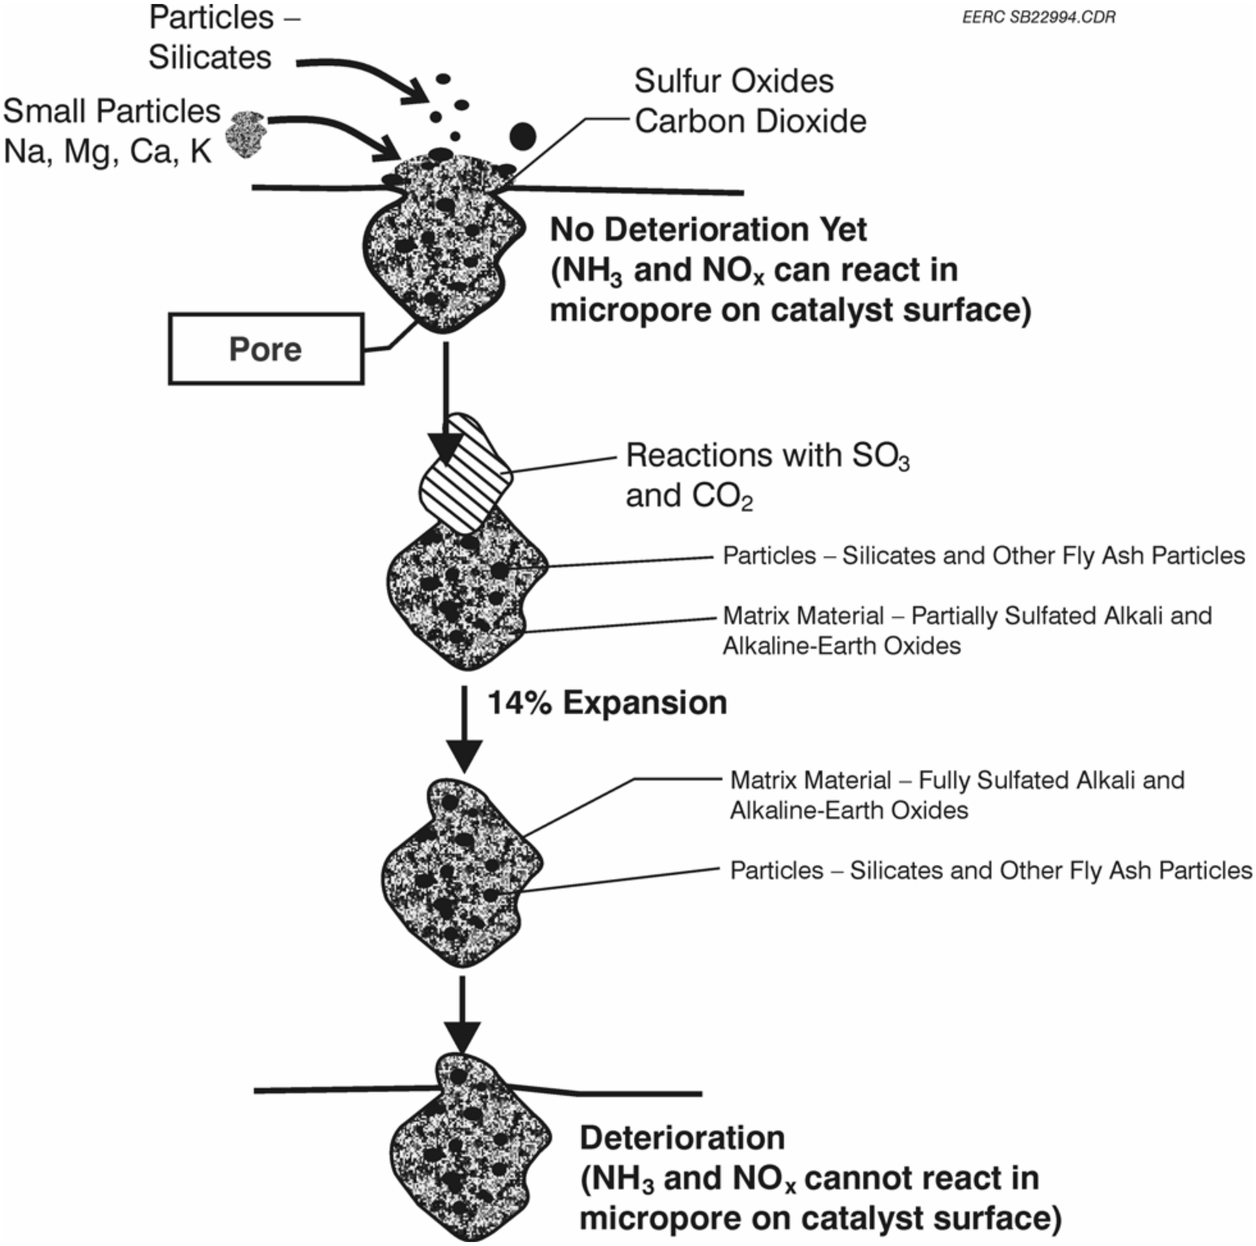

Figure 44. Mechanism of SCR catalyst blinding via the formation of sulfates and carbonates (modified after Pritchard and others [35]).

macroscopic level, there were significant observable accumulations that plugged the entrance as well as the exit of the catalyst sections. On a microscopic level, the ash materials filled pores in the catalyst and, in many cases, completely masked the pores within 4 months of operation. After 6 months of operation, the reactivity of the catalyst from the Baldwin Station was 84% of a comparable reference value.

The deposits on the surfaces and within the pores of the catalyst consisted mainly of sulfated alkali and alkaline-earth element-rich phases. The mechanism for the formation of the

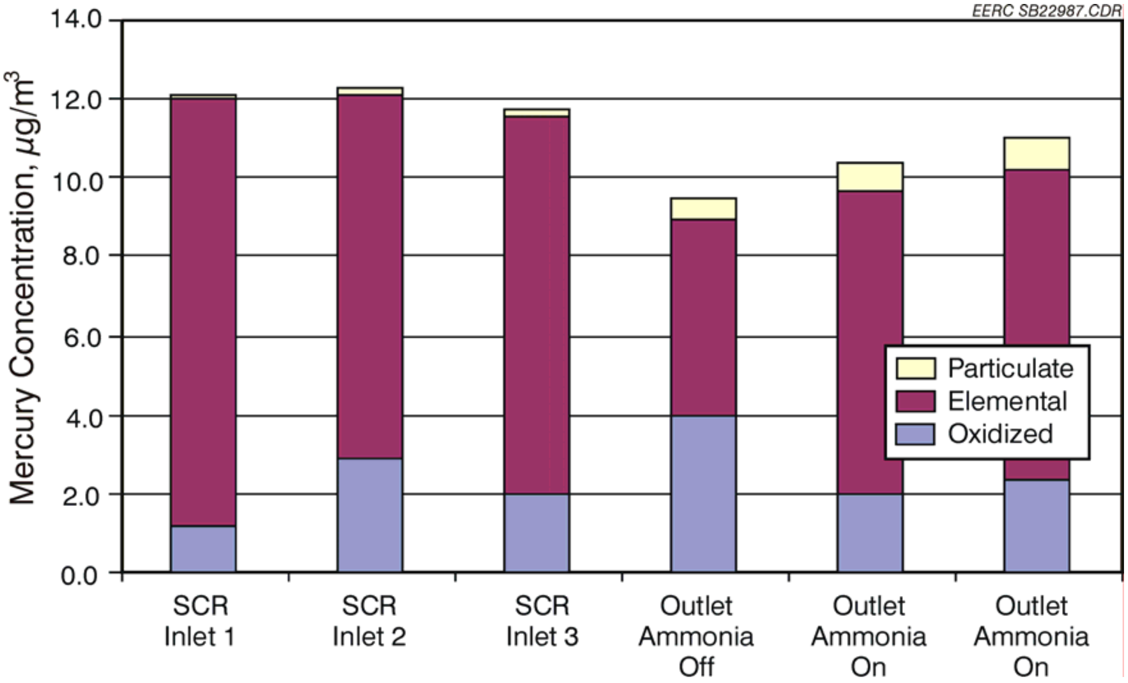

Figure 45. Mercury speciation measurement at the inlet and outlet of the SCR catalyst upon installation of the catalyst.

sulfate materials involves the formation of very small particles rich in alkali and alkaline-earth elements, transport of the particles to the surface of the catalyst, and reactions with SO_2–SO_3 to form sulfates. XRD analysis identified $CaSO_4$ as a major phase and $Ca_3Mg(SiO_4)_2$ and $CaCO_3$ as minor phases. These results are consistent with the bench-scale TGA and FACT modeling results. The only exception may be the absence of phosphate materials predicted in the FACT modeling; one possible explanation is that FACT considers each reaction independently and does not consider the selectivity of one reaction over another.

Lignite and subbituminous coals contain high levels of organically associated alkali and alkaline-earth elements, including sodium, magnesium, calcium, and potassium in addition to mineral phases. During combustion, the inorganic components in the coal are partitioned into various size fractions based on the type of inorganic component and their association in the coal and combustion system design and operating conditions. The results of this testing found that the smaller-sized fractions of ash are dominated by partially sulfated alkali and alkaline-earth elements. The composition of the size fractions was compared to the chemical composition of the ash deposited on and in the catalyst. The comparison shows that the composition of the particle captured in the SCR catalyst is very similar to the <5-µm size fraction.

This study suggests careful evaluation of each SCR installation in applications using subbituminous and lignite coals. Improvements are needed to ensure technical feasibility, especially with lignite-fired units. Installations involving lignite fuels will need advanced cleaning techniques to handle the high sodium and high dust loads associated with burning most lignite fuels.

The ability of mercury to be oxidized across the SCR catalyst was investigated at the Coyote Station. The Coyote Station is fired on North Dakota lignite, and the flue gas is dominated by elemental mercury. Measurement of mercury speciation was conducted using the OH method at the inlet and the outlet of the SCR catalyst. These results show limited oxidation of mercury across the SCR catalyst when lignite coals are fired. The reasons for the lack of mercury oxidation include the following: no chlorine present in the coal and flue gas to catalytically enhance the oxidation of Hg^0, higher levels of alkali and alkaline-earth elements acting as sorbents for any chlorine present in the flue gas, and lower levels of acid gases present in the flue gas.

Dear Ms. Anderson, Mssrs. Edwards, Arnold, Jones, and Gribovicz

RE: WRAP's Reasonable Progress Four Factor Evaluation Project
This letter provides WEST Associates' comments on the Western Regional Air Partnership's (WRAP) reports entitled "Supplementary Information for Four-Factor Analyses for Selected Individual Facilities…" (Four Factor Reports) that were recently prepared by EC/R Incorporated. WEST Associates (WEST) members consist of fifteen utilities operating in the western states with a number of electric generating plants subject to BART and potentially affected by the states' Regional Haze – Reasonable Progress Goal (RH-RPG) assessments.

1661 N. Swan Road Suite 116 • Tucson, AZ 85712 • P: 520.321.1111• F: 520.321.1450• davidss@simginc.com

WEST Associates members reviewed the Four Factor Reports for the following states for selected electric generating plants, as follows:

- Colorado -- 11 Electric Generating Plants
- North Dakota -- 2 Electric Generating Plants
- South Dakota -- 2 Electric Generating Plants
- Wyoming -- 1 Electric Generating Plant

WEST Associates focused its review of the Four Factor Reports on information affecting electric generating units (EGUs) at these plants.

The Four Factor Reports are Inadequate and Should Be Withdrawn

After reviewing the reports, WEST concludes that each of them are wholly inadequate, especially taking into account EPA's *Guidance for Setting Reasonable Progress Goals Under the Regional Haze Program (June 2007 Revision)*[1] ("RP Guidance"). **Therefore, WEST Associates requests that the Four Factor Reports covering Electric Generating Plants be withdrawn from the decision-making and regulatory processes related to regional haze.** In the comments below, WEST provides examples of approaches employed by EC/R in the reports that support this conclusion and request.

WEST is concerned that these Four Factor Reports, as currently constituted, will set a pattern, both in substance and in analytical procedure, that will be followed in response to other states' requests for Four Factor evaluations of other selected EGUs. To perpetuate Four Factor analyses based on the methods used by EC/R in preparation of these reports as currently constituted would not be adequate or helpful to any state in preparing the RPG portions of their RH-SIPs.

Programmatic Consideration of Visibility Improvement Benefit to Achieving the Reasonable Progress Goal is Absent

While the Four Factors do not list visibility improvement as one of the factors, per se, the 40 CFR Part 51.308 regulation governing the development of states' reasonable progress goals, does require consideration of visibility improvement as the results of the Four Factor Reports are used in each state's RPG design and formulation, as follows:

- <u>*First*</u>, the state must not only complete the Four Factor analyses relating to cost effectiveness of control measures on specific sources, the state must also demonstrate *how those factors were taken into account in selecting the goal*. This clearly requires the state to consider cost effective measures in the context of what they will achieve in visibility improvement that is aligned with the desired RPG goal in the RH-SIP. See the following Sec. 308 citations:

---

[1] http://www.wrapair.org/forums/amc/documents/RPguidance.pdf

> 40 CFR 51.308(d)(1)(i) -- "In establishing a reasonable progress goal for any mandatory Class I Federal area within the State, the State must:
>
> > (A) Consider the costs of compliance, the time necessary for compliance, the energy and non-air quality environmental impacts of compliance, and the remaining useful life of any potentially affected sources, *and include a demonstration showing how these factors were taken into consideration in* ***selecting the goal***."
> >
> > (B) ... In establishing the reasonable progress goal, the *State must consider the uniform rate of improvement in visibility and* ***the emission reduction measures needed to achieve it*** for the period covered by the implementation plan."
>
> 40 CFR 51.308(d)(3)(v) -- "The State must consider, at a minimum, the following factors in developing its long-term strategy:
>
> > "... (A) Emission reductions due to ongoing air pollution control programs, including measures to address reasonably attributable visibility impairment; ....
> >
> > (G) The ***anticipated net effect on visibility due to projected changes in point, area, and mobile source emissions*** over the period addressed by the long-term strategy."

- *Second*, the RP Guidelines state that for assessing individual, large scale sources such as EGUs simple cost effectiveness estimates may not be as meaningful as consideration of the value of emission reductions on visibility improvement, as follows:

> "In considering the cost of compliance factor, you should keep in mind that different
> pollutants differently impact visibility impairment. For example, on a ton basis, sulfur dioxide related particles have a greater impact on visibility impairment than crustal material. Therefore, in assessing additional emissions reduction strategies for source categories or individual, large scale sources, ***simple cost effectiveness estimates based on a dollar-per-ton calculation may not be as meaningful as a dollar-per-deciview calculation***, especially if the strategies reduce different groups of pollutants." [RP Guidance, pg. 5-2].
>
> "Another approach you could take, consistent with the "back out" approach discussed in section 2.3, would involve *identifying the set of emissions control measures that achieves the target percentage reductions in visibility-impairing pollutants associated with progress* at or
> beyond the uniform rate of progress. The *selection of control measures to*

> *include in this set*
> *would be guided by your consideration of the statutory factors* and any other factors you have determined are relevant." ."
>
> "Note that for some sources determined to be subject to BART, the State will already have
> completed a BART analysis. *Since the BART analysis is based, in part, on an assessment of many of the same factors that must be addressed in establishing the RPG, it is reasonable to conclude that any control requirements imposed in the BART determination also satisfy the RPG-related requirements for source review in the first RPG planning period*. Hence, you may conclude that no additional emissions controls are necessary for these sources in the first planning period." [RP Guidance, pg. 4-2].

The Four Factor Reports need to include a clear discussion of how their Four Factor cost effectiveness findings are to be integrated within each state's obligation under the EPA's Regional Haze Rule and the RP Guidelines to assess the benefit of and contribution to visibility improvement for achieving the state's RPG.

Nevertheless, WEST is providing the following detailed analysis and comments on the cost effectiveness analyses contained in the above referenced EC/R developed Four Factor Reports, as follows:

Incomplete and Cursory Application of the Four Factors

The "Four Factors"[2] required to be evaluated pursuant to the Clean Air Act and the Regional Haze Rule are acknowledged by the WRAP and EC/R to be necessary review elements for evaluating and setting reasonable progress goals as states develop their Regional Haze SIPs (RH-SIPs). Yet, the essential ingredients for thoroughly and accurately evaluating "cost of compliance" and "remaining useful life of any existing source subject to such requirements" are fundamentally ignored in the EC/R reports.

For example, EPA's RP Guidance includes knowledge and evaluation of site-specific factors, and specific design parameters unique to the evaluated electric generating unit (EGU), cited as follows:

> "To assess compliance costs *for individual sources* or source categories potentially subject to emission limitations, we suggest that you *use established control cost analysis techniques*. For stationary sources, generally this involves the following:
>
> > a) Identify *the emissions units* to be controlled;

---

[2] Cost of compliance; Time necessary for compliance; Energy and non-air quality environmental impacts of compliance; and, Remaining useful life of any existing source subject to such requirements.

> b) Identify *the design parameters for emissions controls*; and
>
> c) Develop cost estimates *based upon those design parameters*.
>
> [States] should evaluate both average *and incremental costs....*"[3] (Emphasis added).

Clearly, EPA's RP Guidance points to a four-factor evaluation process that selects individual EGUs and evaluates "design parameters for emissions controls" unique to each EGU evaluated. Furthermore, "cost estimates based upon those design parameters" must be applied to the "emissions units to be controlled" – once those units are identified. The RP Guidance provides no latitude for the apparent "boiler plate" approach taken in these reports by EC/R.

Inadequate Evaluation of Cost of Compliance

"Established control cost evaluation techniques" include, but are not limited to, the following *essential* evaluative factors:[4]

- Control Options Feasibility for specific EGUs
- Control Option percent Reduction Achievable for specific EGUs
- Control Costs Based on EGU Site-Specific and Operational Factors
- Baseline Emissions Adjusted for Regulatory Required and Committed Control Retrofits to the EGU Prior to RPG Evaluation
- Control Cost Amortization Adjusted for EGU Remaining Useful Life

The Four Factor Reports fail on most of the above "established control cost evaluative techniques." From its review of these reports, WEST supplies examples below to support this conclusion. For purposes of simplicity, WEST is referencing the "2009-05-22 Individual Facility Analyses -- Colorado." The same issues appear in each of the Four Factor Reports.

Control Options Feasibility for the specific EGU

EC/R performed a partial evaluation of control options feasibility for reviewed Colorado EGUs. WEST notes for example, in Table 3-2, that EC/R varies the control technology options between each EGU, based on some knowledge of existing or committed controls. However, there is no discussion in the report to verify EC/R's technical reasons for the

---

[3] *"Guidance for Setting Reasonable Progress Goals Under the Regional Haze Program (June 2007 Revision)"*; Pg. 18; http://www.wrapair.org/forums/amc/documents/RPguidance.pdf

[4] These evaluative factors are a combination of the steps required pursuant to the RP Guidance document for evaluation of control measure options, and practical engineering analysis steps commonly used by power plant engineers when EGUs prepared BART Assessments required by EPA's BART Guidance document (2005).

options listed. As it relates to NOx, each of the reports contain a common listing of low-NOx burners (LNB), LNB with over-fired air (OFA), selective non catalytic reduction (SNCR), and selective catalytic reduction (SCR) (with the lower level controls not listed if currently installed).

This approach has the following two flaws.

First, there is no discussion about whether EGU boiler specific operational and existing design factors would accommodate the listed control option and whether the specific control option would yield NOx reduction capabilities within the percent reduction ranges stated. For example, installation of NOx, PM, and SO2 controls required to meet recently-adopted BART emission limits (unique to the specific EGU design parameters), will directly affect the volume and grid size of SCR catalyst beds required to resolve back pressure issues that can impact the NOx percent removal achievable with SCR. Under some conditions, this will result in infeasibility of SCR.

Also, some EGUs have specific design parameters and operational characteristics that can make installation of SNCR either not feasible or ineffective in achievable NOx percent removal. SNCR involves injection of urea or ammonia within the ductwork flow of combustion flue gas at a carefully designed and tested location of optimum flue gas temperature and residence time. Retrofit installation of SCR or SNCR controls, along with BART-required SO2 scrubbers and PM control devices, require sufficient space. In some cases, limited space is inadequate or unavailable to accommodate the footprint of retrofit equipment. There is no discussion of these specific factors in the reports.

Second, Table 3-2 does not "winnow" the list of control options based on a "baseline" that takes into account BART emission limits for SO2, NOx and PM that most states have promulgated or are in the process of promulgating. There cannot be an accurate Four Factor cost assessment unless baselines are updated with states' adopted BART limits and other EGU committed controls to establish an accurate foundation for Four Factor analyses that may be needed for RPG planning. Nevertheless, achievement of reasonable progress goals may require no further changes in emissions controls after BART is taken into account, and the Four Factor Reports should be revised to reflect this and other possibilities.

Control Option Percent Reduction Achievable for Specific EGUs

Table 3-2 lists Estimated Control Efficiency for each control option in most cases as a range (e.g., SNCR, 30-75%; SCR, 40-90%). It appears that EC/R selected a single percent reduction range for each control technology. This error is repeated across all reports, even though specific EGU analyses will yield unique percent reduction capabilities when taking into account individual EGU parameters.

For example, SNCR and SCR list an average control efficiency of 40% and 80%, without respect to whether these efficiencies are achievable. Given the direct effect this percent reduction assumption has on the outcome of the $/ton cost effectiveness, it is critical that any useful evaluation of control technology options take into account situational and operational factors and characteristics. The generic and unjustified information provided in Table 3-3 is a disservice to both the states that requested these analyses and the EGU sources.

Clearly, there is no attempt by EC/R to identify what achievable percent reduction is appropriate for each specific EGU, given site specific and operational design parameters and performance. Both the minimum achievable percent reduction and the range of expected control performance could differ substantially due to individual EGU site specific and operational/design factors.

Further, no discussion indicates that variability in fuel sulfur content, ash content, and nitrogen content was evaluated. It is well known that these fuel constituents vary, with significant effects on emission control performance. Even in cases where EGU fuel sources are relatively constant (e.g., mine-mouth plants, use of western low sulfur coal), fuel constituent variability exists. A change in coal seam can be accompanied by a shift in ash content, nitrogen content, and sulfur content of coal. Fuel factors such as these need to be evaluated specific to each EGU.

Control Costs Based on EGU Site Specific and Operational Factors

None of the Four Factor Reports indicate that control costs were adjusted or tailored to address individual EGU design parameters and site-specific factors. It appears that EC/R used "look up" tables provided by EPA and other sources to make basic nominal adjustments to capital costs of controls based on capacity, combustion configuration, and other commonly known EGU factors. The purpose of these Four Factor Reports is to inform decisions about reasonableness of control measures to achieve reasonable progress goals. Capital and annual operating costs for controls may vary according to the following:

- Space limitations (after BART controls are installed)
- Requirements to replace, add, or reroute flue gas ducting
- Requirements to add induced draft fans to overcome back pressure accrued by addition of more controls
- Moving and reinstallation of major power plant components to provide space for added controls, such as moving the power plant stack.
- Variability in ammonia or urea use required to achieve minimum required percent control for NOx
- Catalyst replacement schedules.
- Secondary increases in other pollutants resulting from installation of SCR, that further need to be controlled.

An example of how major EGU site and operational specific parameters can significantly affect control costs and, therefore, the need to adjusted control costs to address individual

EGU design and site-specific factors is the retrofit of SCR on coal-fired EGUs operating in the west. Costs associated with SCR may require inclusion of sorbent injection for sulfuric acid mist control, and then potentially a polishing bag house for those EGUs that have ESPs and a scrubber. From at least one WEST utility's experience, SCR will result in a significant increase in sulfuric acid mist that requires the installation of BACT technology. Thus use of sorbent injection to mitigate sulfuric acid mist can in turn result in a significant increase in PM10, which triggers the need for a polishing bag house. Again, this practical example reinforces our comment that there is no generic NOX template that can be applied to western EGUs.

The variability in capital and operating costs can be enough to significantly affect the outcome of the cost effectiveness. Again, there is no evidence in the report to indicate that EC/R considered these practical issues.

Finally, the cost of installing controls (evaluated as $/ton cost effectiveness) has significant variability due to two additional factors not considered by EC/R. First, EC/R used a capital amortization period of 30 years at 7 percent. WEST takes a position that use of a "one size fits all" amortization period is inappropriate and ignores consideration of the remaining useful life of a plant.

With respect to the 7% cost of capital, this is overly simplistic since the actual cost of capital by individual electric generating plants varies substantially in the case of Investor Owned Utilities (IOUs). Depending on the regulatory decision made by the public utilities commission with jurisdiction, and the individual IOU's financial condition, the cost of capital ranges more typically from 8% or 9% up to 13% or higher. At a minimum, EC/R could have surveyed the range of costs of capital that exist among western IOUs and picked a median % cost of capital to use more appropriately in these analyses.

Baseline Emissions Adjusted for Regulatory Required and Committed Control Retrofits to the EGU Prior to RPG Control Measure Evaluation

Table 3-3 cost effectiveness calculations provide only an annual average $/ton result. As cited above, it is *a major omission to not also include incremental $/ton cost effectiveness calculations and results for each EGU*, pursuant to EPA's RP Guidance. The baseline emissions listed for each EGU in Table 3-1 are used for calculating emission reductions, and thereby calculating cost effectiveness results for control options in Tables 3-2 and 3-3. However, the listed NOx and SO2 historical annual emissions in Table 3-1 do not reflect adjustments for the states' recently adopted BART emission limits. Unless, these baseline emissions are adjusted to reflect adopted BART and other EGU committed controls, any Four Factor analysis to be used by states for their 2018 RPG Planning will be inaccurate.

Calculations of cost effectiveness and incremental costs are driven directly by the baseline emissions that will occur after installation and operation of pre-existing regulatory requirements and committed emission controls. Such changes will result in fewer annual tons of emissions by the time the first reasonable progress goal milestone arrives in 2018. As a result, additional reductions to achieve reasonable progress goals will be less or unnecessary, and the $/ton cost effectiveness and incremental costs will be significantly higher (less cost effective) than posed by EC/R in Table 3-3.

Control Cost Amortization Adjusted for EGU Remaining Useful Life

As discussed above, EC/R applied a constant, universal capital cost amortization method based on a 30-year amortization period at 7% cost of capital. EC/R could have surveyed the BART Assessments required by EPA's BART Guidelines (2005) that have been submitted by each EGU owner to each state's air quality regulatory agency. Those BART Assessments (in their cost effectiveness calculations) make statements and assumptions about the remaining useful life of each affected EGU.
EC/R should have used EGU specific information and calculated the cost effectiveness of each control option accordingly.

Conclusion:

WEST Associates strongly urges the WRAP and its states to reject the severely flawed Four Factor Reports. The Four Factor Reports produced by EC/R Incorporated comprise an inadequate and incomplete foundation on which to base discussions regarding the creation of reasonable progress goals and consideration of control measures in developing Regional Haze SIPs.

If you have any questions, or need further information regarding these comments, please contact Lyle Nelson, at lylen@simginc.com.

Sincerely,

Kevin Wanttaja
President of the Board
WEST Associates

Appendix I
Response to Comments

A. **Commentor**: OtterTail Power Co.

Comment 1: It was suggested that 1.01% sulfur be used for evaluating a new wet scrubber for the Coyote Station and the cost effectiveness be recalculated.
Department Response: Agreed. The Department also believes that a new wet scrubber can achieve 95% removal efficiency. The cost effectiveness was recalculated based an average sulfur content of 1.075% for the baseline period of 2004-2005.

Comment 2: OtterTail suggested adding a reference to the concern regarding technical feasibility for high dust SCR.
Department's Response: The Department has addressed this issue as part of the BART process. A reference was added to this assessment.

B. **Commentor**: Basin Electric Power Coop.

Comment 1: Basin believes that a fifth statutory factor, visibility impairment, should be addressed in the document.
Department Response: In determining reasonable progress, Section 169A(g)(1) of the Clean Air Act lists the following factors to be considered:

a. Cost of compliance.
b. Time necessary to compliance.
c. The energy and nonair quality environmental impacts.
d. The remaining useful life of the source.

Visibility impacts are not one of the four factors. However, EPA guidance for determining reasonable progress allows the cost to be determined on a dollar per deciview of visibility improvement.

Comment 2: The text describing the tables in Section 3 does not agree with the labeling of the table.
Department Response: Agreed

Comment 3: Additional options for improving the existing dry FGD system should be evaluated.
Department Response: Such an evaluation was beyond the scope of the general analysis that was prepared.

Comment 4: Agreed with the report statement that high dust SCR may not be technically feasible. Also, visibility improvement should be taken into account in the evaluation of the control technology.
Department Response: See response to Comment A.2 and B.1.

Comment 5: The time to achieve compliance may not be sufficient if the outage schedule for the units (every 3 years) does not fit perfectly into the 5½ - 6½ years for

compliance.
Department Response: Agreed

C. **Commentor**: Hess Corp.

Comment 1: The SRU has a sulfur recovery efficiency of 98.8% instead of the 97.5% used in the calculation of cost effectiveness.

Department Response: The cost effectiveness was recalculated using a 98.55% recovery efficiency which is the value during the baseline period.

Comment 2: Expectations are that the amount of sulfur in the inlet gas will drop in the future due to more sweet gas processed from the Bakken formation.

Department Response: This fact will be considered in the Department's evaluation of the source under the reasonable progress portion of the SIP.

Comment 3: The tail gas cleanup unit cost was extrapolated from a 1982 report which could lead to significant errors.

Department Response: The potential inaccuracy in the cost estimate will be considered in determining whether additional controls will be required under the reasonable progress portion of the SIP.

Comment 4: Electric motors are not a technically feasible option for the Clark engines since the compressor cylinder connecting rods are an integral part of the engines main crankshaft.

Department Response: Agreed

Comment 5: Catalytic convertors are not technically feasible for two cycle lean burn engines.

Department Response: Agreed. However, the cost in the report was for an ammonia/urea based SCR system with a catalyst.

D. **Commentor**: Dakota Gasification Co.

Comment 1: DGC believes the cost of the NO_x control technology in underestimated and control efficiency is overestimated. In order to achieve the proper temperature for SCR, the heat recovery section of the Riley boilers would have to be modified in order to achieve the proper temperature. The required modifications would reduce the capability of the boilers to make enough steam to operate and thereby reduce the plant capacity. In addition, there is limited space for either SNCR or SCR.

Department Response: The Department believes the actual analysis of SCR by DGC has merit. The higher end of cost range will be used to evaluate this alternative.

Comment 2: SCR and SNCR may not be technically feasible for application on the Riley boilers. Testing in 1997 indicated rapid accumulation of ammonium sulfate deposits on the heat recovery section of the boilers.

Department Response: In 1992, the Department determined that SCR and SNCR were not technically feasible for the Riley boilers because of the high CO_2 and high sulfur content of the flue gas. However, SCR and SNCR technology has advanced significantly since that time. The Department agreed that a technical analysis would be required, and perhaps pilot testing, before it could be determined whether the technology could be made to work.

Comment 3: Visibility improvement needs to be included as a fifth factor in the analysis.
Department Response: See response to Comment B.1.

Supplementary Information for Four Factor Analyses by WRAP States

May 4, 2009

Revised Draft Report

Prepared by:

Western Regional Air Partnership (WRAP) and
Western Governors' Association (WGA)
1600 Broadway, Suite 1700
Denver, Colorado 80202

Scope of Document

This document provides an initial analysis of the four factors which must be considered in establishing a reasonable progress goal toward achieving natural visibility conditions in mandatory Class I areas. These factors were examined for several candidate control measures for priority pollutants and emission sources. The results of this report are intended to inform policymakers in setting reasonable progress goals for the Class I areas in the Western Regional Air Partnership (WRAP) region.

This document does not address policy issues, set reasonable progress goals, or recommend a long-term strategy for regional haze. Separate documents will be prepared by the States which address the reasonable progress goals, each state's share of emission reductions, and coordinated emission control strategies.

Disclaimer

The analysis described in this document has been funded by the Western Governors' Association. It has been subject to review by the WGA and the WRAP. However, the report does not necessarily reflect the views of the sponsoring and participating organizations, and no official endorsement should be inferred.

Contents

1. Introduction 1-1
2. Methodology 2-1
   - 2.1 Factor 1 – Costs 2-1
   - 2.2 Factor 2 – Time Necessary for Compliance 2-2
   - 2.3 Factor 3 – Energy and Other Impacts 2-2
   - 2.4 Factor 4 – Remaining Equipment Life 2-3
   - 2.5 References for Section 2 2-4
3. Reciprocating Internal Combustion Engines and Turbines 3-1

1. Introduction

The Regional Haze Rule requires States to set reasonable progress goals toward meeting a national goal of natural visibility conditions in Class I areas by the year 2064. The first reasonable progress goals will be established for the planning period 2008 to 2018. The Western Regional Air Partnership (WRAP), along with its member states, tribal governments, and federal agencies, are working to address visibility impairment due to regional haze in Class I areas. The Regional Haze Rule identifies four factors which should be considered in evaluating potential emission control measures to meet visibility goals. These are as follows:

1. Cost of compliance
2. Time necessary for compliance
3. Energy and non-air quality environmental impacts of compliance
4. Remaining useful life of any existing source subject to such requirements

The purpose of this report is to analyze these factors for possible control strategies intended to improve visibility in the WRAP region. The following priority source categories of emissions are addressed:

1. Reciprocating internal combustion engines and turbines
2. Oil and natural gas exploration and production field operations
3. Natural gas processing plants
4. Industrial boilers
    a. Coal- and oil- fired
        i. By size category
            Up to and including 200 million British Thermal Units (BTU) per hour
            Greater than 200 million BTU/hour
        ii. By age category
            Constructed prior to regulations for Prevention of Significant Deterioration (PSD) (before August 7, 1977)
            After PSD regulations but before the Clean Air Act Amendments of 1990 (August 7, 1977 through December 31, 1990)
            After the Clean Air Act Amendments of 1990
    b. Wood fired industrial boilers
    c. Natural gas fired industrial boilers
5. Cement manufacturing plants
6. Sulfuric acid manufacturing plants
7. Pulp and paper plant lime kilns
8. Petroleum refineries

We have identified control measures for emissions of nitrogen oxides (NO_X) and sulfur dioxide (SO_2), which can react in the atmosphere to produce visibility-obscuring particulate matter on a regional scale, and also for direct emissions of particulate matter. For direct particulate matter emissions, we have evaluated the impacts of control measures on various particulate matter components, including $PM_{2.5}$, PM_{10}, elemental carbon (EC) particulate matter, and particulate organic carbon (OC). Data on emissions of volatile organic compounds (VOC) were also collected. In addition, although VOC emission control measures were not explicitly evaluated in this study, the impacts of NO_X, SO_2, and particulate matter controls on VOC were calculated where co-control benefits would occur.

It must be noted that the source category analyses in this report are general in nature. In developing their Regional Haze State Implementation Plans (SIPs), states will also draw on other category-specific analyses and source-specific analyses.

This report is organized in 10 sections, including this introduction. Section 2 describes the methodology for the four factor analysis. The next 8 sections present the results of factor analyses for the priority emission source categories listed above.

2. Methodology

The first step in the technical evaluation of control measures for a source category was to identify the major sources of emissions from the category. Emissions assessments were initially based on 2002 emissions inventory in the WRAP Emissions Data Management System (EDMS),[1] which consists of data submitted by the WRAP states in 2004. The states then reviewed the emissions data and parameters from the EDMS used for this analysis and provided updated data when applicable. In some cases, detailed data on PM_{10} and $PM_{2.5}$ emissions were not available from the WRAP inventory. Therefore, PM_{10} and $PM_{2.5}$ data from the U.S. Environmental Protection Agency's (EPA) 2002 National Emissions Inventory (NEI) were used to supplement the WRAP inventory where necessary.

Once the important emission sources were identified within a given emission source category, a list of potential additional control technologies was compiled from a variety of sources, including control techniques guidelines published by the EPA, emission control cost models such as AirControlNET[2] and CUECost,[3] Best Available Retrofit Technology (BART) analyses, White Papers prepared by the Midwest Regional Planning Organization (MRPO),[4] and a menu of control options developed by the National Association of Clean Air Agencies (NACAA).[5] The options for each source category were then narrowed to a set of technologies that would achieve the emission reduction target under consideration. The following sections discuss the methodology used to analyze each of the regional haze factors for the selected technologies.

2.1 Factor 1 – Costs

Control costs include both the capital costs associated with the purchase and installation of retrofit and new control systems, and the net annual costs (which are the annual reoccurring costs) associated with system operation. The basic components of total capital costs are direct capital costs, which includes purchased equipment and installation costs, and indirect capital expenses. Direct capital costs consist of such items as purchased equipment cost, instrumentation and process controls, ductwork and piping, electrical components, and structural and foundation costs. Labor costs associated with construction and installation are also included in this category. Indirect capital expenses are comprised of engineering and design costs, contractor fees, supervisory expenses, and startup and performance testing. Contingency costs, which represent such costs as construction delays, increased labor and equipment costs, and design modification, are an additional component of indirect capital expenses. Capital costs also include the cost of process modifications. Annual costs include amortized costs of capital investment, as well as costs of operating labor, utilities, and waste disposal. For fuel switching options, annual costs include the cost differential between the current fuel and the alternate fuel.

The U.S. EPA's *Guidance for Setting Reasonable Progress Goals under the Regional Haze Program* (June 1, 2007) indicates that the four-factor analyses should conform to the methodologies given in the *EPA Air Pollution Control Cost Manual*.[6] This study draws on cost analyses which have followed the protocols set forth in the Cost Manual. Where possible, we have used the primary references for cost data. Cost estimates have been updated to 2007 dollars using the Marshall & Swift Equipment Cost Index or the Chemical Engineering Plant Cost Index, both of which are published in the journal, *Chemical Engineering.*

For Factor 1, results of the cost analysis are expressed in terms of total cost-effectiveness, in dollars per ton of emissions reduced. A relevant consideration in a cost-effectiveness calculation is the economic condition of the industry (or individual facility if the analysis is performed on that basis). Even though a given cost-effectiveness value may, in general, be considered "acceptable," certain industries may find such a cost to be overly burdensome. This is particularly true for well-established industries with low profit margins. Industries with a poor economic condition may not be able to install controls to the same extent as more robust industries. A thorough economic review of the source categories selected for the factor analysis is beyond the scope of this project.

2.2 Factor 2 – Time Necessary for Compliance

For Factor 2, we evaluated the amount of time needed for full implementation of the different control strategies. The time for compliance was defined to include the time needed to develop and implement the regulations, as well as the time needed to install the necessary control equipment. The time required to install a retrofit control device includes time for capital procurement, device design, fabrication, and installation. The Factor 2 analysis also included the time required for staging the installation of multiple control devices at a given facility.

2.3 Factor 3 – Energy and Other Impacts

Table 2-1 summarizes the energy and environmental impacts analyzed under Factor 3. We evaluated the direct energy consumption of the emission control device, solid waste generated, wastewater discharged, acid deposition, nitrogen deposition, and climate impacts (e.g., generation and mitigation of greenhouse gas emissions).

In general, the data needed to estimate these energy and other non-air pollution impacts were obtained from the cost studies which were evaluated under Factor 1. These analyses generally quantify electricity requirements, steam requirements, increased fuel requirements, and other impacts as part of the analysis of annual operation and maintenance costs.

Costs of disposal of solid waste or otherwise complying with regulations associated with waste streams were included under the cost estimates developed under Factor 1, and were evaluated as to whether they could be cost-prohibitive or otherwise negatively affect the facility.

Energy needs and non-air quality impacts of identified control technologies were aggregated to estimate the energy impacts for the specified industry sectors. However, indirect energy impacts were not considered, such as the different energy requirements to produce a given amount of coal versus the energy required to produce an equivalent amount of natural gas.

Table 2-1 Summary of Energy and Environmental Impacts Evaluated Under Factor 3

Energy Impacts
Electricity requirement for control equipment and associated fans
Steam required
Fuel required
Environmental Impacts
Waste generated
Wastewater generated
Additional carbon dioxide (CO_2) produced
Reduced acid deposition
Reduced nitrogen deposition
Benefits from reductions in $PM_{2.5}$ and ozone, where available
Impacts Not Included
Impacts of control measures on boiler efficiency
Energy required to produce lower sulfate fuels
Secondary environmental impacts to produce additional energy (except CO_2) produced

2.4 Factor 4 – Remaining Equipment Life

Factor 4 accounts for the impact of the remaining equipment life on the cost of control. Such an impact will occur when the remaining expected life of a particular emission source is less than the lifetime of the pollution control device (such as a scrubber) that is being considered. In this case, the capital cost of the pollution control device can only be amortized for the remaining lifetime of the emission source. Thus, if a scrubber with a service life of 15 years is being evaluated for a boiler with an expected remaining life of 10 years, the shortened amortization schedule will increase the annual cost of the scrubber.

The ages of major pieces of equipment were determined where possible, and compared with the service life of pollution control equipment. The impact of a limited useful life on the amortization period for control equipment was then evaluated, along with the impact on annualized cost-effectiveness.

3. Reciprocating Internal Combustion Engines and Turbines

Reciprocating engines and turbines at industrial, commercial, and institutional facilities in the WRAP region are estimated to emit about 274,000 tons of NO_X per year, based on the 2002 emissions inventory for the region.[1] These sources are commonly grouped together under the general category of internal combustion engines. Most of the emissions from this category, about 247,000 tons per year, are from sources that are listed in the point source inventory; however, the area sources inventory also includes about 27,000 tons of NO_X emissions from internal combustion engines. The area source emissions estimates are derived from industrial, commercial, and institutional fuel consumption in the WRAP states. NO_X emissions from internal combustion engines represent about 23% of total point source emissions of NO_X in the WRAP region, and about 19% of all stationary source (point and area source) NO_X emissions in the region.

Table 3-1 shows estimated emissions of NO_X, SO_2, PM_{10}, $PM_{2.5}$ and VOC in the WRAP region, broken down by state, engine type, and fuel. The emissions estimates for NO_X, SO_2, and VOC were taken from the WRAP emissions data management system.[1] Estimates for PM_{10} and $PM_{2.5}$ were taken from the National Emissions Inventory (NEI). As the table shows, SO_2, VOC and particulate matter emissions from reciprocating engines and turbines sources are much lower than NO_X emissions. Emissions of OC and EC are not specifically quantified in either the WRAP inventory or the NEI, but can be estimated as a percentage of PM_{10} emissions using data from EPA's SPECIATE database.[2] EC and OC are estimated to comprise 78.8% and 18.5% of diesel PM_{10} emissions; and 38.4% and 24.7% of natural gas combustion PM_{10} emissions, respectively.

The point source emissions estimates in Table 3-1 include reciprocating engines and turbines used in oil and natural gas production and exploration operations, and at natural gas processing facilities. These emissions are included again in Chapters 3 and 4, which discuss control measures for these operations.

Reciprocating engines account for about 64% of the NO_X emissions from point sources in the internal combustion category, and turbines account for about 36%. The area source inventory does not differentiate between reciprocating engines and turbines, but reciprocating engines are expected to make up the bulk of area sources. Most of the turbines burn gaseous fuels, which include natural gas, liquefied petroleum gas, and industrial process gas. Reciprocating engines are divided between gaseous fuels and liquid fuels, such as kerosene and diesel oil.

Emissions from individual diesel reciprocating engines range up to 850 tons of NO_X per year, and natural gas fired reciprocating engine emissions range up to 1,370 tons of NO_X per year. Individual diesel-fired turbines range up to 1,400 tons of NO_X per year, and natural gas turbines range up to 877 tons NO_X per year.[1]

Source: NOX, SO2, and VOC emissions were taken from the WRAP emissions data management system, and PM10 and PM2.5 emissions were taken from the NEI.

Table 3-2 lists potential control measures for NO_X emissions from reciprocating engines and turbines. A number of options were identified for stationary reciprocating engines in an Alternative Control Techniques (ACT) guidance document written by the U.S. EPA in 1993, and in more recent analyses for New Source Performance Standards.[3,4] Reciprocating engines can be designed to operate under rich fuel mixture, or lean fuel mixture conditions. Air-to-fuel-ratio adjustments and ignition retarding adjustments can be used to control emissions under either fuel mixture condition and for diesel or natural gas engines. This approach typically requires the installation of an electronic control system. In addition, fuel efficiency is generally reduced and emissions of soot may be increased. Low-Emission Combustion (LEC) retrofit technology can also reduce emissions from lean burn reciprocating engines by an average of 89%.[5] LEC involves modifying the combustion system to achieve very lean combustion conditions (high air-to-fuel ratios). EPA prepared an update to the ACT guidance for reciprocating engines in 2002 which focused on LEC technology.[5] Selective Catalytic Reduction (SCR) can also be used either alone or in conjunction with the above technologies to reduce NO_X emissions from reciprocating engines or turbines by 90%.[6] In addition, Non-Selective Catalytic Reduction (NSCR) can be used for rich-burn natural gas engines.[4]

A separate ACT guidance document identifies control options for particulate matter emissions from diesel engines.[7] In addition, the WRAP sponsored a study of control options for engines used in the oil and gas industry.[8] This study covered control measures for NO_X, particulate matter, and VOC.

Another ACT guidance document analyzed control options for turbines using gaseous and liquid fuels. [9] Turbines can be retrofit with water or steam injection to reduce emissions by up to 80%. In addition, SCR can be used in conjunction with water or steam injection or low-NO_X burner technology to reduce emissions by 93 to 96%. The ACT did not analyze retrofit installations or low-NOX burner technology for turbines, or impact of SCR used alone (without water or steam injection or low-NO_X burner technology).

3.1 Factor 1 – Costs

Table 3-3 provides cost estimates for the emission control options which have been identified for reciprocating engines and turbines. For each option, the table gives an estimate of the capital cost to install the necessary equipment, and the total annual cost of control, including the amortized cost associated with the capital equipment cost. Retrofit costs were not available for low-NO_X burners.

The capital and annual cost figures are expressed in terms of the cost per unit of engine size, where the engine size is expressed in horsepower for reciprocating engines and million British thermal units per hour (MM-Btu/hr) for turbines. The table shows a range of values for each cost figure, since the cost per unit of engine size will depend on the engine size and other factors. The lower ends of the cost ranges typically reflect larger engines, and the higher ends of the cost ranges typically reflect lower engine sizes. Table 3-3 also shows the estimated cost effectiveness for each control measure, in terms of the cost per ton of emission reduction.

Table 3-2. Control Options for Reciprocating Engines and Turbines

Source Type	Control Technology	Pollutant controlled	Baseline emissions (1000 tons/yr)	Estimated control effieiency (%)	Potential emission reduction (1000 tons/year)	Refer-ences
Turbines	Water or steam injection	NO_X	95	68 - 80	65 - 76	9
	Low-NO_X burners	NO_X	95	68 - 84	65 - 80	9

[a] Costs estimates for low-NO_X burners reflect the incremental costs of new low-NO_X burners versus standard burners. Retrofit costs for existing burners were not available.

[b] NSCR applies only to rich-burn engines. The distribution of emissions between rich-burn and lean-burn engines is not known.

[c] For control measures reducing multiple pollutants, the overall cost-effectiveness is the cost per total reduction of all pollutants. However, EC, OC, and PM2.5 are components of PM10, and therefore are not added separately to the emission reduction total.

3.2 Factor 2 – Time Necessary for Compliance

Once a state decides to adopt a particular control strategy, up to 2 years will be needed to develop the necessary rules to implement the strategy. We have estimated that sources may then require up to a year to procure the necessary capital to purchase control equipment. The Institute of Clean Air Companies (ICAC) has estimated that approximately 13 months is required to design, fabricate, and install SCR or SNCR technology for NO_X control.[10] However, the time necessary will depend on the type and size of the unit being controlled. For instance, state regulators' experience indicates that closer to 18 months is required to install this technology.[11] Additional time up to 12 months may be required for staging the installation process if multiple sources are to be controlled at a single facility. Based on these figures, the total time required achieve emission reductions for reciprocating engines and turbines is estimated at a total of 5½ years.

3.3 Factor 3 – Energy and Other Impacts

Table 3-4 shows the estimated energy and non-air pollution impacts of control measures for reciprocating engines and turbines. In general, air-to-fuel-ratio adjustments and ignition retarding technologies have been found to increase fuel consumption by up to 5%, with a typical value of about 2.5%.[12,13] This increased fuel consumption would result in increased CO_2 emissions. LEC technology is not expected to increase fuel consumption; and may provide some fuel economy.[12]

Diesel oxidation catalyst and diesel filtration technologies would produce an increase in fuel consumption in order to overcome the pressure drop through the catalyst bed and the filter. This is assumed to be roughly the same as the increase in fuel consumption for SCR installations, about 0.5%.[12] In the case of diesel oxidation catalyst, the catalyst would have to be changed periodically, producing an increase in solid waste disposal.[14] If diesel reciprocating engines are replaced with electric motors, there would be an increase in electricity demand, but this would be offset by the fuel consumption that would be avoided by replacing the engine.

For turbines, water injection and steam injection would require electricity to operate pumps and ancillary equipment.[14] Water injection would produce an increase in fuel consumption in order to evaporate the water, and steam injection would require energy to produce the steam. The increased electricity, steam, and fuel demands would produce additional CO_2 emissions.

Installation of SCR on any type of engine would cause a small increase in fuel consumption, about 0.5%, in order to force the exhaust gas through the catalyst bed.[12] This would produce an increase in CO_2 emissions to generate the electricity. In addition, spent catalyst would have to be changed periodically, producing an increase in solid waste disposal.[14]

Table 3-4. Estimated Energy and Non-Air Environmental Impacts of Potential Control Measures for Reciprocating Engines and Turbines

					Energy and non-air pollution impacts (per ton of emission reduced)				
Source Type	Control Technology	Pollutant controlled	Potential emission reduction (1000 tons/year)	Additional fuel requirement (%)	Electricity requirement (kW-hr)	Steam requirement (tons steam)	Solid waste produced (tons waste)	Wastewater produced (1000 gallons)	Additional CO_2 emitted (tons)

NOTES:

blank indicates no impact is expected.

[a] The measure is expected to improve fuel efficiency.

[b] CO_2 from the generation of electricity would be offset by avoided emissions due to replacing the diesel engine

[c] EPA has estimated that the control measures used to meet Tier 4 standards will be integrated into the engine design so that sacrifices in fuel economy will be negligible.

[d] NSCR applies only to rich-burn engines. The distribution of emissions between rich-burn and lean-burn engines is not known.

[e] For control measures reducing multiple pollutants, overall emissions and reflect the sum of all pollutants. However, EC, OC, and $PM_{2.5}$ are components of PM_{10}, and therefore are not added separately to the totals. Impacts are expressed as the impact per ton of total polluants reduced.

3.4 Factor 4 – Remaining Equipment Life

Information was not available on the age of reciprocating engines and turbines in the WRAP region. However, engines in industrial service are often refurbished to extend their lifetimes. Therefore, the remaining lifetime of most reciprocating engines and turbines is expected to be longer than the projected lifetime of pollution control technologies which have been analyzed for this category. In the case of add-on technologies such as SCR, the projected lifetime is 15 years.

If the remaining life of a reciprocating engine or turbine is less than the projected lifetime of a pollution control device, then the capital cost of the control device would have to be amortized over a shorter period of time, corresponding to the remaining lifetime of the emission source. This would cause an increase in the amortized capital cost of the pollution control option, and a corresponding increase in the total annual cost of control. This increased cost can be quantified as follows:

$$A_1 = A_0 + C \times \frac{1-(1+r)^{-m}}{1-(1+r)^{-n}}$$

where:

A_1 = the annual cost of control for the shorter equipment lifetime ($)
A_0 = the original annual cost estimate ($)
C = the capital cost of installing the control equipment ($)
r = the interest rate (0.07)
m = the expected remaining life of the emission source (years)
n = the projected lifetime of the pollution control equipment

4. Oil and Gas Exploration and Production Field Operations

The WRAP region is an important domestic source of crude oil and natural gas. Many of the WRAP states have active production fields for oil and natural gas; and exploration operations are also underway to identify additional reserves. Both the production and exploration industries involve a number of operations which emit NO_X, SO_2, particulate matter and VOC. Turbines are used to drive compressors and other equipment, and diesel engines are used in a variety of applications. Flares and incinerators are used to dispose of waste gases, and process heaters are used in various operations. In addition, emissions emanate from various gas treatment operations, such as glycol dehydrators and amine treatment units.

Table 4-1 summarizes emissions from the industry, broken down by state and by the various emission sources. Point source emissions of NO_X, SO_2, and VOC from these operations were extracted from the 2002 WRAP emissions inventory, which catalogs emission sources by their Standard Industrial Classification (SIC).[1] SIC 131 covers crude petroleum and natural gas production, and SIC 138 covers oil and gas field exploration services. Estimates for PM_{10} and $PM_{2.5}$ were extracted from the 2002 National Emissions Inventory (NEI), which also classifies emissions by SIC. It must be noted that the point source emissions in Table 4-1 for reciprocating engines and turbines in the oil and gas production and exploration sector are also included in the emission totals reported in Table 3-1 (for all reciprocating engines and turbines). However, the point source inventories do not include small engines such as oil well motors and gas well engines. Emissions for these sources have been estimated by the WRAP in a separate oil and gas industry study,[2] and these estimates are also included in Table 4-1.

Based on the inventory emissions estimates, NO_X emissions are the predominant regional haze precursor emissions in oil and gas exploration and production operations. Overall NO_X emissions from these operations are estimated at about 294,000 tons/year, which represent about 20% of stationary source (point and area source) NO_X emissions in the region. These result from combustion processes in engines, turbines, heaters, incinerators, and flares. It should be noted that emissions from point source engines and turbines, about 166,000 tons/year, also fall into the reciprocating engines and turbines category discussed in Chapter 3. However, according to an analysis of oil and gas emission sources sponsored by the WRAP, emissions estimates from small engines at oil and gas operations are not believed to be included in the area source inventory internal combustion estimates.[2]

Most turbines at oil and gas production and exploration operations are fired by natural gas. Emissions from individual natural gas turbines at production operations range up to about 877 tons of NO_X per year, which is comparable to natural gas turbines at industrial facilities. Emissions from individual natural gas turbines at exploration operations range up to 131 tons of NO_X per year. Natural gas reciprocating engines at oil and gas production and exploration operations are somewhat smaller than natural gas reciprocating engines at industrial facilities. NO_X emissions from individual gas reciprocating engines range up to 700 tons per year for oil

and gas production operations, and up to 210 tons per year for exploration operations, compared with a maximum of 1,370 tons per year for reciprocating engines at industrial facilities. Diesel engines at oil and gas operations are also smaller than those at industrial facilities. NO_X emissions from individual diesels range up to 46 tons per year for production operations, and 10 tons per year for exploration operations, compared with 850 tons per year for the largest industrial diesel engine.[1]

SO_2 emissions from oil and gas exploration and production are estimated to be an order of magnitude lower than NO_X emissions. SO_2 emissions from incinerators and flares result from the presence of sulfur compounds in waste gases that are burned at the production site. These are generally the waste gases from natural gas sweetening operations such as amine treatment units. Although the process heaters at oil and gas production facilities are listed as using natural gas fuel, SO_2 emissions from these sources are reported to be about 4,000 tons/year. These emissions may result from the combustion of unsweetened natural gas at the well head. SO_2 emissions from drill rig motors also result from the presence of sulfur compounds in the motor fuels.

PM_{10}, $PM_{2.5}$, and VOC emissions from oil and gas exploration and production are also estimated to be an order of magnitude lower than NO_X emissions. Emissions of OC and EC are specifically quantified in either the WRAP inventory or the NEI, but can be estimated as a percentage of PM_{10} emissions using data from EPA's SPECIATE database.[3] EC and OC are estimated to comprise 78.8% and 18.5% of diesel PM_{10} emissions; and 38.4% and 24.7% of natural gas combustion PM_{10} emissions, respectively.

Table 4-2 lists potential control measures for oil and gas production and exploration emissions. The table includes options for reciprocating engines and turbines, process heaters, flares and incinerators, and sulfur recovery units. As discussed in Chapter 3, a number of options are available to control emissions from gas-fired reciprocating engines, diesel-fueled reciprocating engines, and turbines.[2,4,5,6,7,8] Reciprocating engines can be designed to operate under rich fuel mixture, or lean fuel mixture conditions. Air-to-fuel-ratio adjustments and ignition retarding technologies can be used to control emissions under either fuel mixture condition. Low-Emission Combustion (LEC) retrofit technology which can also reduce emissions from lean burn reciprocating engines by an average of 89%. LEC involves modifying the combustion system to achieve very lean combustion conditions (high air-to-fuel ratios). Selective Catalytic Reduction (SCR) can also be used either alone or in conjunction with the above technologies to reduce NO_X emissions from reciprocating engines or turbines by 90%. In addition, Non-Selective Catalytic Reduction (NSCR) can be used for rich-burn natural gas engines.[8]

SO_2 emissions from incinerators and flares could be avoided by installing sulfur recovery units to remove sulfur from the waste gases prior to incineration or flaring.[9] These emissions can also be reduced by compressing sulfur-containing acid gases and injecting these gases into non-producing rock formations.[10] Flue gas scrubbing has also been used to control SO_2 emissions from incinerators.[11,12] SO_2 emissions from existing sulfur recovery units can be reduced by adding additional recovery stages, or by adding a tail gas treatment unit.[12] In some cases, it may be possible to avoid SO_2 emissions from process heaters by substituting a lower-sulfur sweetened natural gas for the gas currently being burned. A number of options are available to

Table 4-2. Control Options for Oil and Gas Production and Exploration

Source Type	Control Technology	Pollutant controlled	Baseline emissions (1000 tons/yr)	Estimated control efficiency (%)	Potential emission reduction (1000 tons/year)	Refer-ences

Glycol dehydrators	Optimize glycol circulation rate	VOC	3.8	33 - 67	1.3 - 2.6	2

[a] NSCR applies only to rich-burn engines. The distribution of emissions between rich-burn and lean-burn engines is not known.

[b] For control measures reducing multiple pollutants, overall emissions and emission reductions reflect the sum of all pollutants. However, EC, OC, and PM2.5 are components of PM10, and therefore are not added separately to the totals.

[c] Insufficient information is available in the emissions inventory to determine the percentage of flare or incinerator emissions in this category that is amenable to these control strategies.

[d] SCR can be used for mechanical draft process heaters. Natural draft heaters would have to be converted to mechanical draft for installation of SCR.

reduce NO_X emissions from process heaters. Combustion modifications including low-NO_X burners (LNB), ultralow-NO_X burners (ULNB), and flue gas recirculation (FGR) reduce the formation of NO_X. In addition, flue gases from the process heaters can be treated with selective catalytic reduction (SCR) or selective non-catalytic reduction (SNCR) to reduce NO_X emissions. These post-combustion controls can be used either alone or in conjunction with combustion controls.[13,14]

4.1 Factor 1 – Costs

Table 4-3 provides cost estimates for the emission control options which have been identified for oil and gas production and exploration operations. For each option, the table gives an estimate of the capital cost to install the necessary equipment, and the total annual cost of control, including the amortized cost associated with the capital equipment cost. The capital and annual cost figures are expressed in terms of the cost per unit of engine size or per unit of process throughput. Engine size is expressed in horsepower for reciprocating engines and MMBtu/hour for turbines. Throughput for process heaters is also expressed in MMBtu/hour. Process throughput for sulfur recovery units is expressed in terms of the amount of sulfur recovered.

Sulfur recovery units are believed to be more cost-effective than post-combustion controls for reducing SO_2 emissions from flares and incinerators at oil and gas production operations. Recent analyses of controls for Regional Haze precursors have focused on add-on controls for SO_2, rather than such process modifications. However, costs of sulfur recovery units were estimated in an earlier study of model refineries in different size ranges.[9] These estimates have been updated to current dollars using the Chemical Engineering plant cost index.

Table 4-3 shows a range of values for each cost figure, since the cost per unit of process throughput size will depend on the process size and other factors. The lower ends of the cost ranges typically reflect larger engines or processes, and the higher ends of the cost ranges typically reflect smaller engines or processes. The table also shows the estimated cost effectiveness for each control measure, in terms of the cost per ton of emission reduction.

4.2 Factor 2 – Time Necessary for Compliance

Once a state decides to adopt a particular control strategy, up to 2 years will be needed to develop the necessary rules to implement the strategy. We have estimated that sources may then require up to a year to procure the necessary capital to purchase control equipment. The Institute of Clean Air Companies (ICAC) has estimated that approximately 13 months is required to design, fabricate, and install SCR or SNCR technology for NO_X control.[15] However, the time necessary will depend on the type and size of the unit being controlled. For instance, state regulators' experience indicates that closer to 18 months is required to install this technology.[16] In the CAIR analysis, EPA estimated that approximately 30 months is required to design, build, and install SO_2 scrubbing technology for a single emission source.[17] The analysis also estimated that up to an additional 12 months may be required for staging the installation process if multiple sources are to be controlled at a single facility. Based on these figures, the total time required to achieve emission reductions for oil and gas production and exploration operations is estimated at a total of 6½ years.

Table 4-3. Estimated Costs of Control for Oil and Gas Production and Exploration

Source Type	Control Technology	Pollutant controlled	Estimated control efficiency (%)	Estimated capital cost ($/unit)	Estimated annual cost ($/year /unit)	Units	Cost effectiveness ($/ton)	Refer-ences

	Wet FGD	SO_2	90 - 99				1,500 - 1,800	11,12
	Acid gas injection	SO_2	100					10
Sulfur recovery units	Additional recovery stages	SO_2	94 - 96					11,14
	Tail gas treatment unit (TGTU)	SO_2	90 - 99.5				1,100 - 1,200	11,14
Process heaters	Substitution of lower sulfur fuel	SO_2	up to 90					9,12
	LNB	NO_X	40	3.8 - 7.6	0.41 - 0.81	1000 BTU	2,100 - 2,800	13,14
	ULNB	NO_X	75 - 85	4.0 - 13	0.43 - 1.3	1000 BTU	1,500 - 2,000	12,13,14
	LNB and FGR	NO_X	48	16	1.7	1000 BTU	2,600	13,14
	SNCR	NO_X	60	10 - 22	1.1 - 2.4	1000 BTU	4,700 - 5,200	12,13,14
	SCR[d]	NO_X	70 - 90	33 - 48	3.7 - 5.6	1000 BTU	2,900 - 6,700	12,13,14
	LNB and SCR	NO_X	70 - 90	37 - 55	4 - 6.3	1000 BTU	2,900 - 6,300	12,13,14
Glycol dehydrators	Optimize glycol circulation rate	VOC	33 - 67	31 - 170	5 - 28	gal/hr		2

[a] NSCR applies only to rich-burn engines. The distribution of emissions between rich-burn and lean-burn engines is not known.

[b] For control measures reducing multiple pollutants, the overall cost-effectiveness is the cost per total reduction of all pollutants. However, EC, OC, and PM2.5 are components of PM10, and therefore are not added separately to the emission reduction total.

[c] Costs estimates for low-NO_X burners for turbines reflect the incremental costs of new low-NO_X burners versus standard burners. Retrofit costs for existing burners were not available.

[d] SCR cost estimates for process heaters apply to mechanical draft heaters. Natural draft heaters would have to be converted to mechanical draft for installation of SCR. This would increase both the capital and annualized costs of control by about 10%.

4.3 Factor 3 – Energy and Other Impacts

Table 4-4 shows the estimated energy and non-air pollution impacts of control measures for sources at oil and gas production and exploration operations. For gas-fired reciprocating engines and diesel engines, air-to-fuel-ratio adjustments and ignition retarding technologies have been found to increase fuel consumption by up to 5%, with a typical value of about 2.5%.[18,19] This increased fuel consumption would result in increased CO_2 emissions. LEC technology is not expected to increase fuel consumption; and may provide some fuel economy.[18]

Diesel oxidation catalyst and diesel filtration technologies would produce an increase in fuel consumption in order to overcome the pressure drop through the catalyst bed and the filter. In the case of diesel oxidation catalyst, the catalyst would have to be changed periodically, producing an increase in solid waste disposal.[20] If diesel reciprocating engines are replaced with electric motors, there would be an increase in electricity demand, but this would be offset by the fuel consumption that would be avoided by replacing the engine.

For turbines, water injection and steam injection would require electricity to operate pumps and ancillary equipment.[20] Water injection would produce an increase in fuel consumption in order to evaporate the water, and steam injection would require energy to produce the steam. The increased electricity, steam, and fuel demands would produce additional CO_2 emissions.

Installation of SCR on any type of engine would cause a small increase in fuel consumption, about 0.5%, in order to force the exhaust gas through the catalyst bed.[18] This would produce an increase in CO_2 emissions to generate the electricity. In addition, spent catalyst would have to be changed periodically, producing an increase in solid waste disposal.[20]

Sulfur recovery units require electricity and steam. Wet or dry scrubbers applied to incinerators and tail gas treatment units applied to sulfur recovery units would use electricity for the fan power needed to overcome the scrubber pressure drop. These systems would also produce solid waste, and wet scrubbers would produce wastewater which would require treatment. Injection of acid gases would require the consumption of fuel to compress the gases. However, this option would also result in the sequestration of CO2 present in the injected gas stream.[10]

Low-NO_X burners for process heaters are expected to improve overall fuel efficiency. FGR would require additional electricity to recirculate the fuel gas into the heater. In SCR systems for process heaters, fans would be required to overcome the pressure drop through the catalyst bed. The fans would require electricity, with resultant increases in CO_2 to generate the electricity. In addition, spent catalyst would have to be changed periodically, producing an increase in solid waste disposal.[20]

Glycol dehydrators	Optimize glycol circulation rate	VOC	1.3 - 2.6	a					

NOTES:

blank indicates no impact is expected.

[a] The measure is expected to improve fuel efficiency.

[b] CO_2 from the generation of electricity would be offset by avoided emissions due to replacing the diesel engine

[c] EPA has estimated that the control measures used to meet Tier 4 standards will be integrated into the engine design so that sacrifices in fuel economy will be negligible.

[d] Some impact is expected but insufficient information is available to evaluate the impact.

[e] NSCR applies only to rich-burn engines. The distribution of emissions between rich-burn and lean-burn engines is not known.

[f] For control measures reducing multiple pollutants, energy and other impacts are expressed as the impact per per total reduction of all pollutants. (However, EC, OC, and $PM_{2.5}$ are components of PM_{10}, and therefore are not added separately to the emission reduction total.)

[g] Some designs of low-NOX burners and ultralow-NOX burners require the use of pressurized air supplies. This would require additional electricity to pressurize the combustion air.

[h] Acid gas injection is also expected to result in sequestration of the CO_2 present in the acid gas stream.

4.4 Factor 4 – Remaining Equipment Life

Information was not available on the age of oil and gas production and exploration equipment in the WRAP region. The remaining lifetime of most equipment is expected to be longer than the projected lifetime of pollution control technologies which have been analyzed for this category. In the case of add-on technologies, the projected lifetime is 15 years.

If the remaining life of an emission source is less than the projected lifetime of a pollution control device, then the capital cost of the control device would have to be amortized over a shorter period of time, corresponding to the remaining lifetime of the emission source. This would cause an increase in the amortized capital cost of the pollution control option, and a corresponding increase in the total annual cost of control. This increased cost can be quantified as follows:

$$A_1 = A_0 + C \times \frac{1-(1+r)^{-m}}{1-(1+r)^{-n}}$$

where:

A_1 = the annual cost of control for the shorter equipment lifetime ($)
A_0 = the original annual cost estimate ($)
C = the capital cost of installing the control equipment ($)
r = the interest rate (0.07)
m = the expected remaining life of the emission source (years)
n = the projected lifetime of the pollution control equipment

5. Natural Gas Processing Operations

Natural gas processing facilities carry out a number of operations to remove impurities from natural gas before it is piped to consumers. In addition, the gas is typically fractionated to remove propane and heavier hydrocarbons, which are then processed as separate products. Emission sources at natural gas processing facilities include many of the same sources found at gas production operations, discussed in the previous chapter. Turbines and natural gas reciprocating engines are used to drive compressors and other equipment. Flares and incinerators are used to dispose of waste gases, and process heaters are used in various operations. In addition, emissions of SO_2 emanate from sulfur recovery operations at sour natural gas processing plants.

Table 5-1 summarizes emissions from the natural gas processing industry, broken down by state and by the various emission sources. Point source emissions of NO_X, SO_2, and VOC from these operations were extracted from the 2002 WRAP emissions inventory, which catalogs emission sources by their Standard Industrial Classification (SIC).[1] SIC 132 covers natural gas processing. Estimates for PM_{10} and $PM_{2.5}$ were extracted from the 2002 NEI, which also classifies emissions by SIC. It must be noted that the point source emissions in Table 5-1 for reciprocating engines and turbines in the natural gas processing industry are also included in the emission totals reported in Table 3-1 for all reciprocating engines and turbines. However, these emissions are separate from those reported in Table 4-1 for the oil and gas production and exploration sector.

Total NO_X emissions from natural gas processing are estimated at about 31,000 tons/year, and SO_2 emissions are estimated at about 12,000 tons/year. These emissions represent about 2% of stationary source (point and area source) NO_X emissions, and 1% of stationary source SO_2 emissions in the region.

PM_{10} and $PM_{2.5}$ emissions from natural gas processing facilities are estimated to be an order of magnitude lower than NO_X emissions. Emissions of OC and EC are not specifically quantified in either the WRAP inventory or the NEI, but can be estimated as a percentage of PM_{10} emissions using data from EPA's SPECIATE database.[2] EC and OC are estimated to comprise 38.4% and 24.7% of natural gas combustion PM_{10} emissions, respectively.

Emissions from individual reciprocating engines at natural gas processing plants range up to about 1,000 tons per year, compared with 1,373 tons per year for the largest natural gas fired reciprocating engines at industrial facilities. Emissions from individual turbines range up to 338 tons of NO_X per year, compared with 845 tons per year for the largest natural gas turbines at industrial facilities.[1]

Table 5-2 lists potential control measures for natural gas processing emissions. The table includes options for reciprocating engines and turbines, process heaters, flares and incinerators, and sulfur recovery units. As discussed in Chapter 3, a number of options are available to control emissions from gas-fired reciprocating engines, diesel-fueled reciprocating engines, and

Table 5-1. Emissions from Natural Gas Processing in the WRAP Region

Emission source	AK	CA	CO	MT	ND	NM	NV	UT	WY	Tribes	Total

Glycol dehydrators	Optimize glycol circulation rate	VOC	0.32	33 - 67	0.11 - 0.22	7

[a] NSCR applies only to rich-burn engines. The distribution of emissions between rich-burn and lean-burn engines is not

[b] For control measures reducing multiple pollutants, overall emissions and emission reductions reflect the sum of all pollutants. However, EC, OC, and PM2.5 are components of PM10, and therefore are not added separately to the totals.

[c] SCR can be used for mechanical draft process heaters. Natural draft heaters would have to be converted to mechanical draft for installation of SCR.

[d] Insufficient information is available in the emissions inventory to determine the percentage of flare or incinerator emissions in this category that is amenable to these control strategies.

turbines.[3,4,5,6,7,8] Reciprocating engines can be designed to operate under rich fuel mixture, or lean fuel mixture conditions. Air-to-fuel-ratio adjustments and ignition retarding technologies can be used to control emissions under either fuel mixture condition. Low-Emission Combustion (LEC) retrofit technology can also reduce emissions from lean burn reciprocating engines by an average of 89%. LEC involves modifying the combustion system to achieve very lean combustion conditions (high air-to-fuel ratios). Selective Catalytic Reduction (SCR) can also be used either alone or in conjunction with the above technologies to reduce NO_X emissions from reciprocating engines or turbines by 90%. In addition, Non-Selective Catalytic Reduction (NSCR) can be used for rich-burn natural gas engines.[8]

SO_2 emissions from incinerators and flares could be reduced by installing sulfur recovery units to remove sulfur from the waste gases prior to incineration or flaring.[9] These emissions can also be reduced by compressing sulfur-containing acid gases and injecting these gases into non-producing rock formations.[10] Flue gas scrubbing has also been used to control SO_2 emissions from incinerators.[11,12] SO_2 emissions from existing sulfur recovery units can be reduced by adding additional recovery stages, or by adding a tail gas treatment unit.[12] In some cases, it may be possible to avoid SO_2 emissions from process heaters by substituting a lower-sulfur sweetened natural gas for the gas currently being burned. A number of options are available to reduce NO_X emissions from process heaters. Combustion modifications including LNB, ULNB, and FGR reduce the formation of NO_X. In addition, flue gases from the process heaters can be treated with SCR or SNCR to reduce NO_X emissions. These post-combustion controls can be used either alone or in conjunction with combustion controls.[13,14]

5.1 Factor 1 – Costs

Table 5-3 provides cost estimates for the emission control options which have been identified for the natural gas processing industry. For each option, the table gives an estimate of the capital cost to install the necessary equipment, and the total annual cost of control, including the amortized cost associated with the capital equipment cost. The capital and annual cost figures are expressed in terms of the cost per unit of engine size or per unit of process throughput. Engine size is expressed in horsepower for reciprocating engines and MMBtu/hour for turbines. Throughput for process heaters is also expressed in MMBtu/hour. Process throughput for sulfur recovery units is expressed in terms of the amount of sulfur recovered.

Sulfur recovery units are believed to be more cost-effective than post-combustion controls for reducing SO_2 emissions from flares and incinerators at natural gas processing facilities. Recent analyses of controls for Regional Haze precursors have focused on add-on controls for SO_2, rather than such process modifications. However, costs of sulfur recovery units were estimated in an earlier study of model refineries in different size ranges.[9] These estimates have been updated to current dollars using the Chemical Engineering plant cost index.

Table 5-3 shows a range of values for each cost figure, since the cost per unit of throughput will depend on the engine or process size and other factors. The lower ends of the cost ranges typically reflect larger engine or process sizes, and the higher ends of the cost ranges typically reflect smaller engine or process sizes. The table also shows the estimated cost effectiveness for each control measure, in terms of the cost per ton of emission reduction.

5.2 Factor 2 – Time Necessary for Compliance

Once a state decides to adopt a particular control strategy, up to 2 years will be needed to develop the necessary rules to implement the strategy. We have estimated that sources may then require up to a year to procure the necessary capital to purchase control equipment. The Institute of Clean Air Companies (ICAC) has estimated that approximately 13 months is required to design, fabricate, and install SCR or SNCR technology for NO_X control.[15] However, the time necessary will depend on the type and size of the unit being controlled. For instance, state regulators' experience indicates that closer to 18 months is required to install this technology.[16] In the CAIR analysis, EPA estimated that approximately 30 months is required to design, build, and install SO_2 scrubbing technology for a single emission source.[17] The analysis also estimated that up to an additional 12 months may be required for staging the installation process if multiple sources are to be controlled at a single facility. Based on these figures, the total time required achieve emission reductions for natural gas processing facilities is estimated at a total of 6½ years.

5.3 Factor 3 – Energy and Other Impacts

Table 5-4 shows the estimated energy and non-air pollution impacts of control measures for sources at natural gas processing facilities. For gas-fired reciprocating engines and diesel engines, air-to-fuel-ratio adjustments and ignition retarding technologies have been found to increase fuel consumption by up to 5%, with a typical value of about 2.5%.[18,19] This increased fuel consumption would result in increased CO_2 emissions. LEC technology is not expected to increase fuel consumption; and may provide some fuel economy.[18]

For turbines, water injection and steam injection would require electricity to operate pumps and ancillary equipment.[13] Water injection would produce an increase in fuel consumption in order to evaporate the water, and steam injection would require energy to produce the steam. The increased electricity, steam, and fuel demands would produce additional CO_2 emissions.

Installation of SCR on any type of engine would cause a small increase in fuel consumption, about 0.5%, in order to force the exhaust gas through the catalyst bed.[18] This would produce an increase in CO_2 emissions to generate the electricity. In addition, spent catalyst would have to be changed periodically, producing an increase in solid waste disposal.[13]

Table 5-3. Estimated Costs of Control for Natural Gas Processing

Source Type	Control Technology	Pollutant controlled	Estimated control efficiency (%)	Estimated capital cost ($/unit)	Estimated annual cost ($/year /unit)	Units	Cost effectiveness ($/ton)	References
Reciprocating engines, gas	Air-fuel ratio adjustment	NO_X	10 - 40	5.3 - 42	0.9 - 6.8	hp	68 - 2,500	3,7
	Ignition timing retard	NO_X	15 - 30	na	1 - 3	hp	42 - 1,200	3,7

	Wet FGD	SO_2	90 - 99				1,500 - 1,800	11,12
	Acid gas injection	SO_2	100					10
Glycol dehydrators	Optimize glycol circulation rate	VOC	33 - 67	31 - 170	5 - 28	gal/hr		7

[a] NSCR applies only to rich-burn engines. The distribution of emissions between rich-burn and lean-burn engines is not known.

[b] For control measures reducing multiple pollutants, the overall cost-effectiveness is the cost per total reduction of all pollutants. However, EC, OC, and PM2.5 are components of PM10, and therefore are not added separately to the emission reduction total.

[c] Costs estimates for low-NO_X burners for turbines reflect the incremental costs of new low-NO_X burners versus standard burners. Retrofit costs for existing burners were not available.

[d] SCR cost estimates for process heaters apply to mechanical draft heaters. Natural draft heaters would have to be converted to mechanical draft for installation of SCR. This would increase both the capital and annualized costs of control by about 10%.

Table 5-4. Estimated Energy and Non-Air Environmental Impacts of Potential Control Measures for Natural Gas Processing

Glycol dehydrators	Optimize glycol circulation rate	VOC	0.11 - 0.22	a					

NOTES:

blank indicates no impact is expected.

[a] The measure is expected to improve fuel efficiency.

[b] CO_2 from the generation of electricity would be offset by avoided emissions due to replacing the diesel engine

[c] EPA has estimated that the control measures used to meet Tier 4 standards will be integrated into the engine design so that sacrifices in fuel economy will be negligible.

[d] Some impact is expected but insufficient information is available to evaluate the impact.

[e] NSCR applies only to rich-burn engines. The distribution of emissions between rich-burn and lean-burn engines is not known.

[f] Some designs of low-NOX burners and ultralow-NOX burners require the use of pressurized air supplies. This would require additional electricity to pressurize the combustion air.

[g] Acid gas injection is also expected to result in sequestration of the CO_2 present in the acid gas stream.

Sulfur recovery units require electricity and steam. Wet or dry scrubbers applied to incinerators and tail gas treatment units applied to sulfur recovery units would use electricity for the fan power needed to overcome the scrubber pressure drop. These systems would also produce solid waste, and wet scrubbers would produce wastewater which would require treatment. Injection of acid gases would require the consumption of fuel to compress the gases. However, this option would also result in the sequestration of CO_2 present in the injected gas stream.[10]

Low-NO_X burners for process heaters are expected to improve overall fuel efficiency. FGR would require additional electricity to recirculate the fuel gas into the heater. In SCR systems for process heaters, fans would be required to overcome the pressure drop through the catalyst bed. The fans would require electricity, with resultant increases in CO_2 to generate the electricity. In addition, spent catalyst would have to be changed periodically, producing an increase in solid waste disposal. [13]

5.4 Factor 4 – Remaining Equipment Life

Information was not available on the age of natural gas processing equipment in the WRAP region. The remaining lifetime of most equipment is expected to be longer than the projected lifetime of pollution control technologies which have been analyzed for this category. In the case of add-on technologies, the projected lifetime is 15 years.

If the remaining life of an emission source is less than the projected lifetime of a pollution control device, then the capital cost of the control device would have to be amortized over a shorter period of time, corresponding to the remaining lifetime of the emission source. This would cause an increase in the amortized capital cost of the pollution control option, and a corresponding increase in the total annual cost of control. This increased cost can be quantified as follows:

$$A_1 = A_0 + C \times \frac{1-(1+r)^{-m}}{1-(1+r)^{-n}}$$

where:

A_1 = the annual cost of control for the shorter equipment lifetime ($)
A_0 = the original annual cost estimate ($)
C = the capital cost of installing the control equipment ($)
r = the interest rate (0.07)
m = the expected remaining life of the emission source (years)
n = the projected lifetime of the pollution control equipment

6. Industrial Boilers

Industrial boilers encompass the category of boilers used in manufacturing, processing, mining, and refining or any other industry to provide steam, hot water, and/or electricity. There are no specific size definitions for an industrial boiler, however for the purposes of this document, the definition described in Subpart Db of 40 CFR Part 60, New Source Performance Standards (NSPS) for Industrial, Commercial, and Institutional Steam Generating Units will be used. This NSPS regulates steam generating units with a heat input capacity between 100 to 250 MMBtu/hr (29 - 73 MW). Steam generating units greater than 250 MMBtu/hr (73 MW) are subject to the requirements of Subpart D of 40 CFR Part 60.

An industrial boiler report[1] estimated that there are approximately 43,000 industrial boilers operating in the U.S. with an aggregate capacity of 1.5 million MMBtu/hr input. The report noted that approximately half of these industrial boilers are less than 10 MMBtu/hr in size, but account for only 7% of the total capacity. The 2002 WRAP stationary point source emissions tables[2] lists a total of 2,171 facilities with industrial boilers in the 102XXX Source Classification Code (SCC). The majority of the boilers are located at facilities in the food, paper, chemicals, refining and primary metals industries. The most common fuel used for combustion is natural gas with nearly 73% of the facilities in the WRAP region operating natural gas-fired industrial boilers.

Industrial boilers in the WRAP region are estimated to emit about 43,060 tons of NO_X and 28,155 tons of SO_2, based on the 2002 emissions inventory for the region.[3] These boilers utilize the combustion of fuel which includes; coal, oil, natural gas, waste, and wood, to produce steam. Coal-fired industrial boilers comprise of 15,920 tons of NO_X, or 37% of the total NO_X emissions, and 14,376 tons, or 51% of the total SO_2 emissions from industrial boilers in the WRAP region. Industrial boilers represent about 4.1% of the total point source emissions of NO_X, and about 3.4% of the total SO_2 point source emissions in the WRAP region.

Table 6-1 shows estimated emissions of NO_X, SO_2, PM_{10}, $PM_{2.5}$, and VOC from the WRAP emissions inventory, broken down by state and fuel. The table shows that PM_{10}, $PM_{2.5}$, and VOC emissions from industrial boilers are significantly lower than the NO_X and SO_2 emissions. Emissions of PM from these sources were not included in the inventory, but are expected to be much lower than the NO_X and SO_2 emissions. As the table shows, coal-fired boilers were the most significant source of NO_X, SO_2, and VOC emissions in the WRAP region. For NO_X, coal fired boilers accounted for about 56% of the emissions from point sources, and 41% of the total stationary source emissions in the WRAP region.

Table 6-2a lists potential control measures for NO_X, SO_2, PM_{10}, $PM_{2.5}$, EC, and OC emissions from coal-fired and oil-fired industrial boilers. Table 6-2b presents control options for natural gas boilers, and Table 6-2c provides control options for wood-fired industrial boilers for each of these pollutants. Uncontrolled emission rates were obtained from the respective AP-42 section for each of the fuels.[4] Control technology options were identified using information from industrial boiler control option studies.[5] The control options were divided into appropriate control technologies for each of the four fuels; coal, oil, natural gas, and wood.

Table 6-2d lists potential control options for NO_X, SO_2, PM_{10}, $PM_{2.5}$, EC, and OC coal-fired and oil-fired industrial boilers by age. These pollutants are regulated under the Clean Air Act (CAA) to attain and maintain National Ambient Air Quality Standards (NAAQS), reduce acidic deposition, and improve visibility under regional haze regulations. To attain and maintain the NAAQS, the EPA enacted the Prevention of Significant Deterioration (PSD) regulations to establish maximum pollution concentration levels to protect public health and welfare from harmful levels of pollutants. The PSD regulations require new major sources or major modifications at existing sources to install "Best Available Control Technology (BACT)" and conduct ambient air quality analyses to show that the new source or modification will not cause or contribute to a violation of any applicable NAAQS or PSD increment. Because PSD requirements are on a case-by-case basis, the age groups were segregated into using the New Source Performance Standards (NSPS) to show control options and emission levels for coal-fired and oil-fired industrial boilers. The age groups are designated as pre-NSPS, post-NSPS, and post CAA amendments of 1990.

[1] Uncontrolled coal-fired emission rates calculated using AP-42 emission factors for PC, dry bottom, wall-fired, bituminous Pre-NSPS. The emission factor was converted to lb/MMBtu assuming MT coal with a heat rate of 17.5 MMBtu/ton, a sulfur content of 0.62 weight percent sulfur, and an ash content of 11.5 percent.

[2] Uncontrolled oil-fired emission rates calculated using AP-42 emission factors for No. 6 oil fired, normal firing. The emission factor was converted to lb/MMBtu assuming a distillate oil heat content of 140,000 Btu/gal, and a sulfur content of 0.60 weight percent sulfur.

[1] Uncontrolled coal-fired emission rates calculated using AP-42 emission factors for PC, dry bottom, wall-fired, bituminous Pre-NS The emission factor was converted to lb/MMBtu assuming MT coal with a heat rate of 17.5 MMBtu/ton, a sulfur content of 0.62 weight percent sulfur, and an ash content of 11.5 percent.

[2] Uncontrolled oil-fired emission rates calculated using AP-42 emission factors for No. 6 oil fired, normal firing. The emission factor was converted to lb/MMBtu assuming a distillate oil heat content of 140,000 Btu/gal, and a sulfur content of 0.60 weight percent sulfur.

[3] Uncontrolled coal-fired emission rates calculated using AP-42 emission factors for PC, dry bottom, wall-fired, bituminous Post-N The emission factor was converted to lb/MMBtu assuming MT coal with a heat rate of 17.5 MMBtu/ton, a sulfur content of 0.62 weight percent sulfur, and an ash content of 11.5 percent.

[4] Uncontrolled oil-fired emission rates calculated using AP-42 emission factors for No. 6 oil fired, normal firing. The emission factor was converted to lb/MMBtu assuming a distillate oil heat content of 140,000 Btu/gal, and a sulfur content of 0.60 weight percent sulfur.

[5] Uncontrolled Coal fired and oil-fired emission rates are base the the 40 CFR 60, Subpart Db limits for each of the fuels.

6.1 Factor 1 – Costs

Table 6-3 provides cost estimates for the emission control options which have been identified for each of the industrial boilers. For each option, the table gives an estimate of the capital cost to install the necessary equipment, and the total annual cost of control, including the amortized cost associated with the capital equipment cost. The capital cost values are expressed in terms of the cost per heat input (MMBtu/hr) to the boiler. The annual cost is presented in millions of dollars per year. The table shows a range of values for each cost figure, since the capital cost will depend on the rated heat input to the boiler and other factors. The lower ends of the capital and annual cost ranges typically reflect smaller sized boilers, and the higher ends of the capital and annual cost ranges reflect larger sized boilers. Table 3-3 also shows the estimated cost effectiveness for each control measure, in terms of the cost per ton of emission reduction. Lower cost effectiveness values generally reflect the larger heat input boiler sizes, whereas higher cost effectiveness values reflect lower heat input boilers sizes.

6.2 Factor 2 – Time Necessary for Compliance

Once a state decides to adopt a particular control strategy, up to 2 years will be needed to develop the necessary rules to implement the strategy. We have estimated that sources may then require up to a year to procure the necessary capital to purchase control equipment. The Institute of Clean Air Companies (ICAC) has estimated that approximately 18 months is required to design, fabricate, and install SCR or SNCR technology for NO_X control, and approximately 30 months to design, build, and install SO_2 scrubbing technology.[9] Additional time of up to 12 months may be required for staging the installation process if multiple boilers are to be controlled at a single facility. Based on these figures, the total time required to achieve emission reductions for industrial boilers is estimated at a total of 5½ years for NO_X strategies, and 6½ years for SO_2 strategies.

6.3 Factor 3 – Energy and Other Impacts

Table 6-4 shows the estimated energy and non-air pollution impacts of control measures for industrial boilers. The values were obtained from a report summarizing the applicability and feasibility of control options for industrial boilers.[8] In general, the combustion modification technologies (LNB, OFA, FGR) do not require steam or generate solid waste, wastewater, or additional CO_2. They also do not require additional fuel to operate, and in some cases may decrease fuel usage because of the optimized combustion of the fuel.

Retrofitting of a SNCR requires energy for compressor power and steam for mixing. This would produce a small increase in CO_2 emissions to generate electricity; however the technology itself does not produce additional CO_2 emissions.

Installation of SCR on an industrial boiler is not expected to increase fuel consumption. However additional energy is required to operate the SCR, which will produce an increase in CO_2 emissions to generate the electricity. In addition, spent catalyst would have to be changed periodically, producing an increase in solid waste disposal.

	ESP	PM$_{2.5}$, PM$_{10}$	0.5 - 1.5 kW/1000 acfm				

NOTES:
A blank cell indicates no impact is expected.

For SO_2 control technologies, energy is required material preparation (e.g., grinding), materials handling (e.g., pumps/blowers), flue gas pressure loss, and steam requirements. Power consumption is also affected by the reagent utilization of the control technology, which also affects the control efficiency of the control technology.

PM control technologies require energy to operate compressors, heaters, and ash handling. In addition, an additional fan may be required to reduce the flue gas pressure loss by the ESP or FF. The ESP also requires energy to operate the transformer-rectifier. These energy requirements will produce an increase in CO_2 emissions to generate the required electricity.

6.4 Factor 4 – Remaining Equipment Life

Similar to Electric Generating Units (EGUs), industrial boilers do not have a set equipment life. Since many of the strategies are market-based reductions applied to geographic regions, it is assumed that control technologies will not be applied to units that are expected to be retired prior to the amortization period for the specific control equipment. Therefore, the remaining life of an industrial boiler is not expected to affect the cost of control technologies for industrial boilers.

7. Cement Kilns

The main emission units of interest at cement plants are the cement kilns. There are two major types, wet and dry kilns; dry kilns are further categorized as long dry, preheater, or precalciner kilns. On the whole, wet kilns tend to produce more tons of cement (or "clinker") but also require more energy than dry process kilns. There was limited information on SO_2 controls for cement kilns, particularly for long wet kilns.[1] Process modification and replacement of a wet kiln with a dry process kiln are the most feasible options for SO_2 control.

Cement kilns at cement manufacturing facilities in the WRAP region are estimated to emit about 40,610 tons of NO_X; 6,230 tons of SO_2; 1,573 tons of $PM_{2.5}$; 4,245 tons of PM_{10} and 4,467 tons of VOC per year, based on the 2002 emissions inventory for the region and WRAP updates.[2] Most of the emissions from this category are from the kilns themselves; the remainder of the emissions is generated primarily from the transfer of clinker and the grinding and drying of the raw material. NO_X emissions from cement kilns represent approximately 4% of total point source emissions of NO_X in the WRAP region, and approximately 3% of all stationary source (point and area source) NO_X emissions in the region. SO_2 emissions from cement kilns represent approximately 0.75% of total point source emissions of SO_2 in the WRAP region, and approximately 0.68% of all stationary source (point and area source) SO_2 emissions in the region.

Table 7-1 shows estimated emissions of NO_X, SO_2, PM_{10}, $PM_{2.5}$ and VOC from the WRAP emissions inventory and updated data provided by the states, broken down by state and emission source. As the table shows, SO_2, PM_{10}, $PM_{2.5}$ and VOC emissions from cement kiln sources are much lower than NO_X emissions. Emissions of particulate matter from these sources were not included in the WRAP EDMS inventory – the emissions presented were gathered from the NEI. Long dry kilns produce over half of the NO_X emissions (54.8%) and most of the $PM_{2.5}$ and PM_{10} emissions (79.4 and 71.3%, respectively) generated by cement manufacturing in the WRAP region. Long wet kilns produce almost half of the SO_2 emissions generated by the cement manufacturing (48.4%), and precalciner kilns produce almost half of the VOC emissions generated by cement manufacturing (45.6%).

Table 7-2 lists potential control measures for NO_X emissions from cement kilns. A number of options were identified for cement kilns in an ACT guidance document written by the U.S. EPA in 1994.[6] Cement kilns use coal, waste products, tires, or natural gas for combustion fuel - this combustion generates primarily NO_X emissions but also produces SO_2 and PM emissions.[6] Controls can be broken into three categories: process modifications, combustion modifications and NO_X removal controls. Process modifications include fuel switching and the inclusion of steel slag into the raw kiln feed (also known as the CemStar$^{(TM)}$ process) which improves thermal efficiency. CemStar is currently used in TXI's Hunter and Midlothian, TX plants, TXI's Oro Grande, CA plant and Holcim's North Texas Cementer plant. TXI has also licensed CemStar out to RMC Pacific Materials, Inc. and to the Rio Grande Portland Cement Company.[3] Combustion modifications include low NO_X burners and mid-kiln firing. NO_X removal controls include SCR, SNCR, LoTOX^{TM}, and biosolids or sorbent injection. Low NO_X

burners reduce flame turbulence, delay fuel/air mixing and create fuel-rich zones for initial combustion, reducing the flame temperature and thus NO_X formation.[4] SCR introduces ammonia, presented as a catalyst, into the clinker making process to selectively reduce NO_X emissions from exhaust gases. SNCR, available to preheater or precalciner cement kilns[1,5,6], does not use a catalyst to reduce NO_X emissions. Instead, the process uses either ammonia or urea that is generated when reagents are injected into the kiln at specific temperatures. However, SNCR has been tested primarily in European facilities; there have been two demonstrations in the United States but no kilns have yet adopted the technology.[7,8,9,10,11]

In the LoTOx™ system, ozone is injected into the kiln which oxidizes NO_X. The resulting higher oxides of nitrogen can then be removed by a wet scrubber.[12] LoTOx is licensed by the BOC group and is currently being used on the Midlothian cement wet kilns in Texas.[1,12] Biosolid or absorbent injection is similar to SNCR, although instead of a catalyst either biosolids from wastewater treatment plants or limestone/hydrated lime are injected into the kiln.[7,13] Biosolid injection is being used in one kiln in Southern California where dewatered sewage sludge is injected into the mixing chamber where the flue gas streams from the kiln and the precalciner mix together. [14,15]

7.1 Factor 1 – Costs

Table 7-3 provides cost estimates for the emission control options which have been identified for cement kilns. For each option the table gives an estimate of the capital cost to install the necessary equipment and the total annual cost of control, including the amortized cost associated with the capital equipment cost. The capital and annual cost figures are expressed in terms of the cost per unit of clinker tonnage produced, or cubic feet per minute (cfm) for PM emission sources. The table shows a range of values for each cost figure since the cost per unit of clinker tonnage will depend on the amount of clinker produced and other factors. The lower ends of the cost ranges typically reflect smaller kilns and the higher ends of the cost ranges typically reflect larger kiln sizes. Table 7-3 also shows the estimated cost effectiveness for each control measure, in terms of the cost per ton of emission reduction.

7.2 Factor 2 – Time Necessary for Compliance

Once a state decides to adopt a particular control strategy, up to 2 years will be needed to develop the necessary rules to implement the strategy. We have estimated that sources may then require up to a year to procure the necessary capital to purchase control equipment. The ICAC has estimated that approximately 13 months is required to design, fabricate, and install SCR or SNCR technology for NO_X control.[16] However, state regulators' experience indicates that closer to 18 months is required to install this technology.[17] Additional time of up to 12 months may be required for staging the installation process if multiple sources are to be controlled at a single facility. Based on these figures, the total time required to achieve emission reductions for cement kilns is estimated at a total of 5½ years.

a The CemStar process has been analyzed for long wet and dry kilns only although the process is currently being used in long dry kilns and preheater/precalciner kilns at two facilities, one in Texas and one in California. It is unknown what the control efficiency is of the CemStar process in preheater or precalciner kilns.

7.3 Factor 3 – Energy and Other Impacts

Table 7-4 shows the estimated energy and non-air pollution impacts of control measures for cement kilns. In general in-combustion NO_X control technologies will increase energy efficiency of the cement production process since these technologies reduce excess air and burning.[18] SCR requires additional energy input since the process required a particular gas temperature, requiring the gas stream to be reheated. An additional 9.8 percent of the total energy required in cement manufacturing will be needed to utilize the SCR control technology.[18] In addition, spent catalyst would have to be changed periodically, producing an increase in solid waste disposal.[19]

7.4 Factor 4 – Remaining Equipment Life

Information was not available on the age of cement kilns in the WRAP region. Cement kilns have no set equipment life. The units, whether wet or dry, can be refurbished to extend their lives. In addition, it is assumed that controls will be not be applied to units that are expected to be retired prior to the amortization period for the control equipment. Therefore, remaining equipment life is not expected to affect the cost of control for cement kilns.

Table 7-3. Estimated Costs of Control for Cement Kilns

Source Type	Control Technology	Pollutant controlled	Estimated control efficiency (%)	Estimated capital cost ($1000/unit)	Estimated annual cost ($/year/unit)	Units	Cost effectiveness ($/ton)	References
Long Wet Kiln	Low NOX burners (indirect fired)	NOX	20-47	401 - 564	100,000 - 144,000	ton clinker	270 - 620	1, 6, 7
	Low NOX burners (direct fired)	NOX	20-47	1,910	376,000 - 343,500	ton clinker	855 - 1,005	1, 6, 7
	Mid-kiln firing	NOX	20-50	613 - 3,205	183,500 - (192,300	ton clinker	(460) - 730	1, 6, 7, 8

a References discussing this particular control technology did not provide any capital or annual costs but only a cost effectiveness figure.

b The CemStar process has been costed for long wet kilns only although the process is currently being used in long dry kilns and preheater/precalciner kilns at two facilities, one in Texas and one in California.

c The cost effectivenes was calculated for a wet kiln that did not already have a scrubber system in place.

d Cost effectiveness figures for LoTOx were not determined for dry kilns or preheater kilns, but only for wet kilns (the kilns that currently use the system) and precalciner kilns (developed from vendor information).

e The cost effectiveness was calculated for a precalciner kiln that already has a scrubber system in place.

a - The measure is expected to improve fuel efficiency.

b - Impacts are expected, however there is no available information to quantify these impacts.

c - According to the ERG Report (reference 3) "electricity and oxygen costs are reported to be high" although there is no quantification given.

8. Sulfuric Acid Manufacturing Plants

Sulfuric acid manufacturing plants account for about 4,700 tons/year of SO_2 emissions in the WRAP region. These emissions are from a limited number of facilities, with facility-level SO_2 emissions ranging from about 100 tons/year to about 2,000 tons/year. Table 8-1 summarizes emissions from the sulfuric acid manufacturing plants, broken down by state, based on the WRAP emissions inventory and the NEI.[1] The table also shows the amounts of SO_2 emissions from facilities at different efficiency levels for the acid recovery process. As the table shows, reported emissions of NO_X, PM_{10}, $PM_{2.5}$, and VOC emissions are much lower than SO_2 emissions from sulfuric acid plants in the region.

Emissions of SO_2 from sulfuric acid manufacturing processes can be reduced by increasing the absorption efficiency of the acid recovery process. The NSPS emission level for sulfuric acid plants corresponds to an estimated recovery efficiency of 99.75%.[2] Based on the SCC used in the WRAP inventory, the recovery efficiency ranges from 93 to 99% for most of the emission sources in the WRAP region. Increasing the efficiency of sulfuric acid plants to the NSPS level would result in emission reductions 75 to 96.4% from the current baseline level of control. This increase in efficiency is achieved by adding more absorption stages to the acid recovery process. SO_2 emissions can also be controlled using tail gas treatment units.[3,4] Table 8-2 shows the estimated control efficiencies and emission reductions which could be achieved for sulfuric acid plants operating at different baseline levels of control.

8.1 Factor 1 – Costs

Table 8-3 provides cost estimates for the emission control options which have been identified for sulfuric acid manufacturing plants. For each option, the table gives an estimate of the capital cost to install the necessary equipment, and the total annual cost of control, including the amortized cost associated with the capital equipment cost. The capital and annual cost figures are expressed in terms of the cost per unit of gas treated, in actual cubic feet per minute (acfm).

Table 8-3 shows a range of values for each cost figure, since the cost per unit of throughput will depend on the process size and other factors. The lower ends of the cost ranges typically reflect larger processes, and the higher ends of the cost ranges typically reflect lower process sizes. The table also shows the estimated cost effectiveness for each control measure, in terms of the cost per ton of emission reduction.

Table 8-1. Emissions from Sulfuric Acid Manufacturing Plants in the WRAP Region

	CA	ID	WA	WY	Tribes	All

8.2 Factor 2 – Time Necessary for Compliance

Once a state decides to adopt a particular control strategy, up to 2 years will be needed to develop the necessary rules to implement the strategy. We have estimated that sources may then require up to a year to procure the necessary capital to purchase control equipment. In the CAIR analysis, EPA estimated that approximately 30 months is required to design, build, and install SO_2 scrubbing technology for a single emission source.[5] The analysis also estimated that up to an additional 12 months may be required for staging the installation process if multiple sources are to be controlled at a single facility. Based on these figures, the total time required achieve emission reductions for sulfuric acid manufacturing facilities is estimated at a total of 6½ years.

8.3 Factor 3 – Energy and Other Impacts

Table 8-4 shows the estimated energy and non-air pollution impacts of control measures for sulphuric acid plants. Additional absorption stages to increase acid plant efficiency would require additional electricity and steam,[2] as would a tailgas treatment unit.[4] This would result in increased CO_2 emissions to generate the electricity and steam.

8.4 Factor 4 – Remaining Equipment Life

Information was not available on the age of sulfuric acid plants in the WRAP region. However, industrial processes often refurbished to extend their lifetimes. Therefore, the remaining lifetime of most equipment is expected to be longer than the projected lifetime of pollution control technologies which have been analyzed for this category. In the case of add-on technologies, the projected lifetime is 15 years.

If the remaining life of an emission source is less than the projected lifetime of a pollution control device, then the capital cost of the control device would have to be amortized over a shorter period of time, corresponding to the remaining lifetime of the emission source. This would cause an increase in the amortized capital cost of the pollution control option, and a corresponding increase in the total annual cost of control. This increased cost can be quantified as follows:

$$A_1 = A_0 + C \times \frac{1-(1+r)^{-m}}{1-(1+r)^{-n}}$$

where:

A_1 = the annual cost of control for the shorter equipment lifetime ($)
A_0 = the original annual cost estimate ($)
C = the capital cost of installing the control equipment ($)
r = the interest rate (0.07)
m = the expected remaining life of the emission source (years)
n = the projected lifetime of the pollution control equipment

Table 8-4. Estimated Energy and Non-Air Environmental Impacts of Potential Control Measures for Sulfuric Acid Manufacturing Plants

				Energy and non-air pollution impacts (per ton of pollutant reduced)			
Source Type	Control Technology	Pollutant controlled	Potential emission reduction (tons/year)	Additional electricity requirement (kW-hr)	Steam requirement (tons steam)	Solid waste produced (tons waste)	Additional CO_2 emitted (tons)
Contact process

9. Pulp and Paper Lime Kilns

The pulp making process produces the largest amount of emissions in the pulp and paper industry, accounting for more than 75% of the sector's $PM_{2.5}$, SO_2, and NO_X emissions.[1] The role of lime kilns in the kraft pulping process is to produce white liquor and calcium carbonate.[2]

Lime kilns at pulp and paper manufacturing facilities in the WRAP region are estimated to emit about 828 tons of NO_X, 104 tons of SO_2, 603 tons of $PM_{2.5}$, 667 tons of PM_{10}, and 32 tons of VOC per year, based on the 2002 emissions inventory for the region.[3] The area source emissions estimates are derived from industrial, commercial, and institutional fuel consumption in the WRAP states. NO_X emissions from lime kilns represent approximately 0.08% of total point source emissions of NO_X in the WRAP region, and approximately 0.06% of all stationary source (point and area source) NO_X emissions in the region. SO_2 emissions from lime kilns represent approximately 0.01% of total point source emissions of SO_2 in the WRAP region, and approximately 0.01% of all stationary source (point and area source) SO_2 emissions in the region.

Table 9-1 shows estimated emissions of NO_X, SO_2, PM_{10}, $PM_{2.5}$ and VOC from the WRAP emissions inventory and updated data provided by the states, broken down by state and emission source. As the table shows, SO_2, PM_{10}, $PM_{2.5}$ and VOC emissions from lime kiln sources are much lower than NO_X emissions. PM emissions from these sources were not included in the WRAP EDMS inventory – the emissions presented were gathered from the 2002NEI.

Table 9-2 lists potential control measures for NO_X, SO_2, PM_{10} and $PM_{2.5}$ emissions from lime kilns. A number of options were identified for lime kilns in the AirControlNet documentation report written by Pechan in 2006.[4] Many of the controls listed are similar to those to control emissions from cement kilns (please see chapter 7). SCR and SNCR have been investigated as possible control technologies but have been found to be technically infeasible. Additionally, according to the NACAA, there are no technically feasible methods for controlling NO_X emissions from lime kilns.[1] Therefore NACAA discusses control options for PM emissions only.

9.1 Factor 1 – Costs

Table 9-3 provides cost estimates for the emission control options which have been identified for lime kilns used in the pulp and paper industry. For each option, the table gives an estimate of the capital cost to install the necessary equipment, and the total annual cost of control, including the amortized cost associated with the capital equipment cost. The capital and annual cost figures are expressed in terms of the cost per standard cubic feet per minute (scfm). The table shows a range of values for each cost figure, since the cost per scfm will depend on the

Table 9-1. Emissions from Lime Kilns in the WRAP Region

	Dry ESP	OC	161	95-98	153 - 158	4

kiln size and other factors. The lower ends of the cost ranges typically reflect smaller kilns, and the higher ends of the cost ranges typically reflect larger kilns. Table 9-3 also shows the estimated cost effectiveness for each control measure, in terms of the cost per ton of emission reduction.

9.2 Factor 2 – Time Necessary for Compliance

Once a state decides to adopt a particular control strategy, up to 2 years will be needed to develop the necessary rules to implement the strategy. We have estimated that sources may then require up to a year to procure the necessary capital to purchase control equipment. The ICAC has estimated that approximately 13 months is required to design, fabricate, and install SCR or SNCR technology for NO_X control.[5] However, state regulators' experience indicates that closer to 18 months is required to install this technology.[6] Additional time of up to 12 months may be required for staging the installation process if multiple sources are to be controlled at a single facility. Based on these figures, the total time required to achieve emission reductions for pulp and paper lime kilns is estimated at a total of 5½ years.

9.3 Factor 3 – Energy and Other Impacts

Table 9-4 shows the estimated energy and non-air pollution impacts of control measures for pulp and paper lime kilns. Low NO_X burners negatively affect efficiency and energy usage,[7] and staged combustion, while lowering NO_X emissions, can lead to increased SO_2 emissions. SCR and SNCR require, on average, 890 kilowatt-hour (kWh) of electricity per ton of pollutant reduced, and 0.25 tons of steam for every ton of pollutant reduced. Approximately one ton of CO_2 is produced per mWh of electricity generated.[8] In addition, spent catalyst from the SCR technology would have to be changed periodically, producing an increase in solid waste disposal.[9] Installation of SCR would also require an increase in fuel consumption, which would also produce an increase in CO_2 emissions to generate the electricity.

Fabric filters and ESP technologies, on average, generate approximately one ton of solid waste for every ton of pollutant reduced. It is also likely that there will be additional electricity usage for in-combustion and post-combustion technologies.

9.4 Factor 4 – Remaining Equipment Life

Information was not available on the age of reciprocating engines and turbines in the WRAP region. However, lime kilns, like cement kilns, have no set equipment life. These units can be refurbished to extend their lives. In addition, it is assumed that controls will be not be applied to lime kilns that are expected to be retired prior to the amortization period for the control equipment. Therefore, remaining equipment life is not expected to affect the cost of control for lime kilns.

Table 9-3. Estimated Costs of Control for Lime Kilns

10. Oil Refineries

Petroleum refineries in the WRAP region are estimated to emit about 25,000 tons of NO_X and 58,000 tons of SO_2, based on the WRAP emissions inventory. These emissions represent about 2% of stationary source (point and area source) NO_X emissions, and 6% of stationary source SO_2 emissions in the region. PM_{10} and $PM_{2.5}$ emissions from natural gas processing facilities are estimated to be an order of magnitude lower than NO_X and SO_2 emissions.

Table 10-1 summarizes estimated emissions from petroleum refineries in the WRAP region, broken down by state and by the various emission sources. These emissions estimates are based on the 2002 WRAP emissions inventory.[1] Major sources of NO_X and SO_2 emissions at refineries in the WRAP region include process heaters, catalytic cracking units, coking units and ancillary operations, flares and incinerators. Other sources include boilers, which have been discussed in Chapter 6, and reciprocating engines and turbines, which have been discussed in Chapter 3.

Emissions of OC and EC are not specifically quantified in either the WRAP inventory or the NEI, but can be estimated as a percentage of PM_{10} emissions using data from EPA's SPECIATE database.[2] EC and OC are estimated to comprise 0.07% and 0.014% of PM_{10} emissions from catalytic cracking units, respectively; 38.4% and 24.7% of natural gas combustion PM_{10} emissions; and 1% each in oil combustion PM_{10}.

Table 10-2 lists potential control measures for emissions of SO_2, NO_X, and PM at petroleum refineries. The table includes options for process heaters, fluid catalytic cracking units, fluid coking operation boilers, coke calcining boilers, and flares.

Most of the SO_2 emissions from process heaters result from the burning of refinery fuel gases containing hydrogen sulfide (H_2S). These emissions can be reduced by treating the refinery fuel gas to remove H_2S before the gas is burned. A number of options are available to reduce NO_X emissions from process heaters. Combustion modifications including LNB, ULNB, and FGR reduce the formation of NO_X. In addition, flue gases from the process heaters can be treated with SCR or SNCR to reduce NO_X emissions. These post-combustion controls can be used either alone or in conjunction with combustion controls.[3,4]

In catalytic cracking, the heavier fractions of crude petroleum are treated with a catalyst which breaks the petroleum molecules into lighter compounds. The catalyst is continuously cycled between the cracking and a separate regeneration reactor in order to burn off coke build-up. Since the catalyst coke contains relatively high levels of sulfur, the combustion products from this coke are an important source of SO_2 emissions. Uncontrolled SO_2 concentrations in the fluid catalytic cracking (FCC) regenerator exhaust stream range from 150 to 3000 parts per million by volume (ppmv). The FCC regenerator burner also emits NO_X and PM, including material abraded from the catalyst (catalyst fines). Uncontrolled NO_X emissions from the regenerator vent can range from 50 to 400 ppmv.[5]

	Flare gas recovery system	SO_2		varies		5

Many refineries use catalyst additives to reduce SO_2 and NO_X emissions from fluid catalytic cracking units. SO_2 emissions can also be reduced by treating the fluid catalytic cracker feed stream to remove sulfur compounds. Some refineries in the U.S. have also used SCR to control NO_X emissions from catalytic cracking units, and one refinery in Japan has also used SNCR.[6,7] In addition, the LoTOx^{TM} process has been developed to control NO_X emissions in the catalytic cracking regenerator offgas. In this system, ozone is injected into the offgas to convert the nitrogen oxide (NO) and nitrogen dioxide (NO_2) which comprise NO_X into more highly oxidized forms of nitrogen such as dinitrogen pentoxide (N_2O_5). These more highly oxygenated compounds are more soluble in water, and are removed from the offgas stream in a wet scrubber. An emission control efficiency of 90% has been reported for this system.[5,8] However, the LoTOx^{TM} system is more cost effective if used in conjunction with a wet scrubber to control SO_2 emissions. Wet scrubbers are often used for simultaneous control of PM, SO_2, and NO_X emissions from the catalyst regenerator.[9] In addition, cyclones and ESP are commonly used to control PM emissions in the catalyst regenerator offgas.[5,10]

SO_2 emissions from fluid coking and coke calcining operations result from the combustion of a portion of the coke in a coke burner. Wet scrubbers have been used to control SO_2 emissions from the coking unit, with reported efficiencies of 95% to over 99%.[11] The emission streams from a coke calciner incinerator and from the coke burner in a fluid coking unit are similar to the emission streams from a boiler.[11] Therefore, it is believed that NO_X emissions from these streams can be controlled using SCR or SNCR.[12,13]

Petroleum refineries use flares to burn combustible gases that must be vented from various processes and cannot be practically processed or recovered. These gases generally emanate from non-steady-state operations, such as start-up, shut-down, process maintenance, and process upsets. Some of these operations are predictable, and others are not. SO_2 emissions from flaring result from the flaring of sour gases or other gases which have high concentrations of sulfur compounds. These emissions can often frequently be reduced through the use of improved process controls or improved training of process operators. Emissions can also be reduced by expanding the sulfur recovery unit to handle all of the acid gases produced by the refinery, and by optimizing the performance of the sulfur recovery unit. All of these measures are designed to reduce the number of times that sulfur-containing gases are flared.[5]
A flare gas recovery system can also be used to capture waste gases before they are flared, and hold the gases until they can be treated to remove sulfur compounds.[5] NO_X emissions during flaring events can be mitigated by combustion controls such as steam injection.

10.1 Factor 1 – Costs

Table 10-3 provides cost estimates for the emission control options which have been identified for petroleum refineries. For each option, the table gives an estimate of the capital cost to install the necessary equipment, and the total annual cost of control, including the amortized cost associated with the capital equipment cost. The capital and annual cost figures are expressed in terms of the cost per unit process throughput.

Table 10-3. Estimated Costs of Control Petroleum Refineries

Source Type	Control Technology	Pollutant controlled	Estimated control effieiency (%)	Estimated capital cost ($1000/unit)	Estimated annual cost ($/year/unit)	Units	Cost effectiveness ($/ton)	Refer-ences
Process heaters	Fuel treatment to remove sulfur	SO_2	up to 90	3.4 - 10	28,000 - 36,000	Refinery capacity, 1000 barrels/day	1,300 - 1,700	5,13
	LNB	NO_X	40	2.7 - 7.6	290 - 810	MM-Btu/hr	650 - 2,800	3,6
	ULNB	NO_X	75 - 85	2.8 - 13	300 - 1,300	MM-Btu/hr	400 - 2,000	3,5,6
	LNB and FGR	NO_X	48	5.8 - 16	640 - 1,700	MM-Btu/hr	1,000 - 2,600	3,6
	SNCR	NO_X	60	5.2 - 22	570 - 2,400	MM-Btu/hr	890 - 5,200	3,5,6
	SCR[b]	NO_X	70 - 90	33 - 48	3,700 - 5,600	MM-Btu/hr	2,900 - 6,700	3,5,6
	LNB and SCR	NO_X	70 - 90	37 - 55	4,000 - 6,300	MM-Btu/hr	2,900 - 6,300	3,5,6
Fluid catalytic cracking units	Catalyst additives for NO_X reduction	NO_X	46	not available[a]				5,7
	LoTOX™	NO_X	85				1,700 - 2,000	5,8
	SNCR	NO_X	40 - 80				2500	5,7
	SCR	NO_X	80 - 90				2500	7,8
	Catalyst additives for SO_2 absorbtion	SO_2	20 - 60	not available[a]				5,7
	Desulfurization of catalytic cracker feed	SO_2	up to 90	23 - 54	190,000 - 250,000	Refinery capacity, 1000 barrels/day	6,200 - 8,000	7,13
	Wet scrubbing	SO_2	70 - 99				1,500 - 1,800	5,6,9
	ESP	$PM_{2.5}$, PM_{10}, EC,OC	95+				>10,000	5,6,10
Coking or coke calcining boiler offgas	Spray dryer absorber	SO_2	80 - 95				1,500-1,900	5
	Wet FGD	SO_2	90 - 99				1,500 - 1,800	5,11,12
Flares	Improved process control and operator training	SO_2	Varies	not available[a]				5
	Expand sulfur recovery unit	SO_2	Varies	not available[a]				5
	Flare gas recovery system	SO_2	Varies	not available[a]				5

[a] Costs of process modifications will depend on the specific refinery configuration.

[b] SCR cost estimates for SCR apply to mechanical draft heaters. Natural draft heaters would have to be converted to mechanical draft for installation of SCR. This would increase both the capital and annualized costs of control by about 10%.

Sulfur recovery units are believed to be more cost-effective than post-combustion controls for reducing SO_2 emissions from flares and incinerators at natural gas processing facilities. Recent analyses of controls for Regional Haze precursors have focused on add-on controls for SO_2, rather than such process modifications. However, costs of sulfur recovery units were estimated in an earlier study of model refineries in different size ranges.[14] These estimates have been updated to current dollars using the Chemical Engineering plant cost index.

Table 10-3 shows a range of values for each cost figure, since the cost per unit of throughput will depend on the process size and other factors. The lower ends of the cost ranges typically reflect larger engine or process sizes, and the higher ends of the cost ranges typically reflect smaller process sizes. The table also shows the estimated cost effectiveness for each control measure, in terms of the cost per ton of emission reduction.

10.2 Factor 2 – Time Necessary for Compliance

Once a state decides to adopt a particular control strategy, up to 2 years will be needed to develop the necessary rules to implement the strategy. We have estimated that sources may then require up to a year to procure the necessary capital to purchase control equipment. The ICAC has estimated that approximately 13 months is required to design, fabricate, and install SCR or SNCR technology for NO_X control.[15] However, state regulators' experience indicates that closer to 18 months is required to install this technology.[16] In the CAIR analysis, EPA estimated that approximately 30 months is required to design, build, and install SO_2 scrubbing technology for a single emission source.[17] The analysis also estimated that up to an additional 12 months may be required for staging the installation process if multiple sources are to be controlled at a single facility. Based on these figures, the total time required achieve emission reductions for oil refineries estimated at a total of 6½ years.

10.3 Factor 3 – Energy and Other Impacts

Table 10-4 shows the estimated energy and non-air pollution impacts of control measures for sources at petroleum refineries. Process modifications to desulfurize process gases burned in process heaters would generally require increases in catalytic hydrotreatment processing. These modifications may increase the generation of spent catalyst, which would need to be treated as a solid waste or a hazardous waste. Low NO_X burners for process heaters are expected to improve overall fuel efficiency.[3] FGR would require additional electricity to recirculate the fuel gas into the heater. In SCR systems for process heaters or other sources, fans would be required to overcome the pressure drop through the catalyst bed. The fans would require electricity, with resultant increases in CO_2 to generate the electricity. In addition, spent catalyst would have to be changed periodically, producing an increase in solid waste disposal.[10]

Catalyst additives for reducing NO_X and SO_2 emissions from fluid catalytic cracking units are likely to result in increased generation of spent catalyst, which would have to be disposed as hazardous waste. These catalyst additives may also result in increases in fuel consumption. However, information is not available to quantify these impacts. A LoTOx

Table 10-4. Estimated Energy and Non-Air Environmental Impacts of Potential Control Measures for Petroleum Refineries

					Energy and non-air pollution impacts (per ton of emission reduced)				
Source Type	**Control Technology**	**Pollutant controlled**	**Potential emission reduction (1000 tons/year)**	**Additional fuel requirement (%)**	**Electricity requirement (kW-hr)**	**Steam requirement (tons steam)**	**Solid waste produced (tons waste)**	**Wastewater produced (1000 gallons)**	**Additional CO_2 emitted (tons)**
Process heaters	Fuel treatment to remove sulfur	SO_2	0 - 11	b					b

	Expand sulfur recovery unit	SO_2	Varies	d	d	d			d
	Flare gas recovery system	SO_2	Varies	d	d	d			d

NOTES:

blank indicates no impact is expected.

[a] The measure is expected to improve fuel efficiency.

[b] CO_2 from the generation of electricity would be offset by avoided emissions due to replacing the diesel engine

[c] EPA has estimated that the control measures used to meet Tier 4 standards will be integrated into the engine design so that sacrifices in fuel economy will be negligible.

[d] Some impact is expected but insufficient information is available to evaluate the impact.

[e] Some designes of low-NOX burners and ultralow-NOX burners require the use of pressurized air supplies. This would require additional electricity to pressurize the combustion

scrubbing system or wet scrubbing system applied to the fluidized catalytic cracking unit would require electricity to operate fans and other auxiliary equipment, and would produce a wastewater stream which would require treatment. In addition, sludge from the scrubber would require disposal as solid waste. SCR and SNCR systems would also require electricity for fans, and SCR systems would produce additional solid waste because of spent catalyst disposal. Dust captured by an ESP or fabric filter would also require disposal as a solid waste. The presence of catalyst fines in the dust may require treatment as a hazardous waste.

Sulfur recovery units require electricity and steam. Wet or dry scrubbers applied to incinerators and tail gas treatment units applied to sulfur recovery units would use electricity for the fan power needed to overcome the scrubber pressure drop. These systems would also produce solid waste, and wet scrubbers would produce wastewater which would require treatment.

10.4 Factor 4 – Remaining Equipment Life

Information was not available on the age of processes at petroleum refineries in the WRAP region. However, industrial processes often refurbished to extend their lifetimes. Therefore, the remaining lifetime of most equipment is expected to be longer than the projected lifetime of pollution control technologies which have been analyzed for this category. In the case of add-on technologies, the projected lifetime is 15 years.

If the remaining life of an emission source is less than the projected lifetime of a pollution control device, then the capital cost of the control device would have to be amortized over a shorter period of time, corresponding to the remaining lifetime of the emission source. This would cause an increase in the amortized capital cost of the pollution control option, and a corresponding increase in the total annual cost of control. This increased cost can be quantified as follows:

$$A_1 = A_0 + C \times \frac{1-(1+r)^{-m}}{1-(1+r)^{-n}}$$

where:

A_1 = the annual cost of control for the shorter equipment lifetime ($)
A_0 = the original annual cost estimate ($)
C = the capital cost of installing the control equipment ($)
r = the interest rate (0.07)
m = the expected remaining life of the emission source (years)
n = the projected lifetime of the pollution control equipment

Tom Bachman, P.E.
Senior Environmental Engineer
Division of Air Quality
North Dakota Department of Health
Environmental Health Section
Gold Seal Center, 918 E. Divide Ave.
Bismarck, North Dakota 58501-1947

Dear Mr. Bachman:

Thank you for inviting us to provide comments on the Best Available Retrofit Technology (BART) analyses and draft permits provided by the North Dakota Department of Health (ND DOH) for Coal Creek Station Units #1 & #2, Leland Olds Station Units #1 & #2, Milton R. Young Station Units #1 & #2, and Stanton Station Unit #1. Our interest in this action stems from our obligation to protect visibility at Theodore Roosevelt National Park (NP) and Lostwood National Wildlife Refuge (NWR). We commend ND DOH for the progress your proposals represent toward reducing emissions from these facilities. We have enclosed our station-specific comments and provide general comments below that apply to all or several of these facilities.

By its nature, lignite is a very low-rank fuel that is relatively high in sulfur compared to its heating value. For this reason, it is also relatively inexpensive. We believe that the economic benefits derived by sources burning this fuel should be considered in determining what level of emission control can reasonably be expected from the standpoint of a level, industry-wide playing field.

For several units, ND DOH is proposing alternative sulfur dioxide (SO_2) limits that are similar to the presumptive BART limits because they allow a source to choose between a limit in terms of pounds of emissions per million Btu of heat input, or percent reduction of that pollutant. While EPA presented its BART Guidelines for SO_2 in that format, we do not believe that it was EPA's intention to allow the source to choose the more favorable limit. By definition, BART represents the highest degree of control that meets the five-factor test. Where ND DOH has determined that a lb/mmBtu limit is reasonable, it should require that that limit be met. Similarly, where ND DOH has determined that a percent reduction limit is reasonable, it should require that that limit be met. If both limits are determined to be reasonable, then to allow the source to choose only one clearly does not represent the most stringent reasonable degree of control. Therefore, where ND DOH has proposed alternative limits, both should be required.

There is also a fundamental problem with setting only a percent-reduction limit on SO_2 emissions. If fuel sulfur content increases, emissions can increase correspondingly. Unless sulfur content is limited, or a cap is placed on mass emissions (e.g., lb/hr, tons/yr), the actual amount of SO_2 emitted is unlimited.

We also have some general comments that apply to all of the Particulate Matter (PM) analyses. We believe that the BART analyses are deficient in that they neither address upgrades to the existing Electrostatic Precipitators (ESPs) or propose limits that realistically reflect the capabilities of those existing ESPs, as well as the proposed new baghouses, to control filterable PM. EPA's BART Guidelines (Guidelines) advise:

- "...it is important to include control options that involve improvements to existing controls and not to limit the control options only to those measures that involve a complete replacement of control equipment."
- "...for retrofitting existing sources in addressing BART, you should consider ways to improve the performance of existing control devises, particularly when a control device is not achieving the level of control that other similar sources are achieving in practice with the same device. For example, you should consider requiring those sources with electrostatic precipitators (ESPs) performing below currently achievable levels to improve their performance."

Although all of these sources have ESPs in place, none of them except Stanton Unit #1 is currently achieving a level of performance equivalent to the 0.015 lb/mmBtu proposed for ESPs at sources such as Peabody's Thoroughbred and LG&E's Trimble County projects in Kentucky. Furthermore, EPA has recently issued a permit limiting the Desert Rock facility to 0.010 lb/mmBtu filterable PM_{10}, new baghouses are being permitted at 0.009 – 0.012 lb/mmBtu in Virginia (Virginia Hybrid Energy Center) and Wyoming (Dry Fork, WYGEN 3), and ND DOH proposed to permit the Gascoyne project at 0.012 lb/mmBtu.

In addition to an absence of any evaluation of upgrading the existing PM control equipment, it appears that ND DOH is not following EPA guidance to consider more stringent emission rates in setting permit limits:

> "If you find that a BART source has controls already in place which are the most stringent controls available (note that this means all possible improvements to any control devices have been made), then it is not necessary to comprehensively complete each following step of the BART analysis in this section. As long as these most stringent controls available are made federally enforceable for the purpose of implementing BART for that source, you may skip the remaining analyses in this section."

We recommend that ND DOH establish permit limits that reflect the capabilities of the BART technology to control filterable PM.

Cost-Effectiveness Metrics

When generating cost-effectiveness numbers, it is very important to put those numbers into the proper perspective. Although ND DOH presented average cost-effectiveness of a given control strategy in terms of cost-per-ton-of-pollutant-removed ($/ton), we have a concern with the way in which the incremental cost analysis is used by ND DOH. According to EPA's BART Guidelines, "You should consider the incremental cost effectiveness **in combination with the average cost effectiveness** [*emphasis added*] when considering whether to eliminate a control option…You should exercise caution not to misuse these [average and incremental cost effectiveness] techniques… [but consider them in situations where an option shows]…slightly greater emission reductions…" Reviewing agencies are quite familiar with the concept of total average cost and expect to see costs in the \$2,000 – \$12,000 per ton range. However, incremental costs are rarely estimated and evaluated, so the much higher numbers that result appear quite high at first glance. For this reason, rigid use of incremental cost effectiveness will always result in the choice of the cheapest option if carried to the extreme. (For example, if only incremental costs were used to evaluate PM controls, it is likely that all controls more expensive than a multiple cyclone would be rejected.) To use incremental costs properly, they must be compared to incremental costs for similar situations. Despite the EPA guidance, ND DOH appears to base its determinations primarily on the incremental cost-effectiveness.

Furthermore, the simple \$/ton test does not address the issue of proximity to one or more Class I areas. We believe that the cost/deciview (\$/dv) metric can also be an appropriate tool to evaluate the costs and benefits of reducing emissions from a source that is relatively close to one or more Class I areas. For example, we calculated that the cost-effectiveness for SO_2 controls at Great River Energy's Stanton #1 would be \$12 - 15 million/dv of visibility improvement at Theodore Roosevelt NP. As can be seen, \$/dv is typically much higher (by orders of magnitude) than \$/ton.

Finally, BART is not necessarily the most cost-effective solution. Instead, it represents a broad consideration of technical, economic, energy, and environmental (including visibility improvement) factors.

Visibility Improvement Metrics

We believe that it is appropriate to consider both the degree of visibility improvement in a given Class I area as well as the cumulative—not average—effects of improving visibility across all of the Class I areas affected. It simply does not make sense to use the same metric to evaluate the effects of reducing emissions from a BART source that impacts only one Class I area as for a BART source that impacts multiple Class I areas.

The BART Guidelines represent an attempt to create a workable approach to estimating visibility impairment. As such, they require several assumptions, simplifications, and shortcuts about when visibility is impaired in a Class I area, and how much impairment is occurring. The Guidelines do not attempt to address the geographic extent of the impairment, but assume that all Class I areas are created equal, and that there is no difference between widespread impacts in a Class I area and isolated impacts in a Class I area. To address the problem of geographic extent, we have been looking at the cumulative impacts of a source on all Class I areas affected, as well as the cumulative benefits from reducing emissions. While there are certainly more sophisticated approaches to this problem, we believe that this is the most practical, especially when considering the modeling techniques and information available. Therefore, until we can develop a second-level, more refined analysis, we continue to believe that our "simple summing" approach fills a void left by ND DOH in cases of power plants having significant impacts upon two Class I areas.

As an extension of our Stanton #1 example (above), we also calculated that the cumulative cost-effectiveness for SO_2 controls would be \$6 - 7 million/dv of visibility improvement at Theodore Roosevelt NP and Lostwood NWR. Such a cumulative approach can dramatically alter the way in which the cost-effectiveness of an alternative is evaluated.

Once again, we commend ND DOH for the significant progress its proposals represent. We look forward to working with ND DOH and EPA as this process advances. We believe that good communication and sharing of information will help expedite this process, and suggest that you contact Don Shepherd--NPS (don_shepherd@nps.gov, 303-969-2075), or Meredith Bond--FWS (meredith_bond@fws.gov, 303-914-3808) if you have any questions or comments.

National Park Service (NPS) and U.S. Fish and Wildlife Service (FWS) Source-Specific Comments on North Dakota Department of Health (ND DOH) Proposed BART Permits
August 11, 2008

Great River Energy (GRE) Coal Creek Units #1 & #2

Great River Energy (GRE) operates Coal Creek Units #1 & #2 near Underwood, North Dakota. Both units are tangentially-fired with lignite from an adjacent mine and are rated at 550 MW (gross) output. Current emission control equipment consists of wet limestone scrubbers, Low-NO_x Burners (LNB) and Separated Overfire Air (SOFA), and Electrostatic Precipitators (ESPs). Although each unit has a capacity greater than 200 MW at a facility with a total capacity greater than 750 MW, presumptive BART limits only apply for nitrogen oxide (NO_x) because there are existing sulfur dioxide (SO_2) controls on both units at the facility.

SO_2: GRE has proposed to upgrade the existing wet scrubbers to meet 0.15 lb/mmBtu.[1] ND DOH has proposed that Coal Creek meet either 0.15 lb/mmBtu or demonstrate 94% SO_2 control.
While we agree with the proposed scrubber upgrade, we believe that the chosen approach could be implemented more effectively. Although control-effectiveness information presented in Table 5-2 of GRE's August 2006 submittal estimates SO_2 control efficiency at 93.9% - 96% for the scrubber upgrade, it appears that ND DOH is assuming that it is not possible to upgrade the existing scrubbers to achieve better than 94% control. Furthermore, GRE has estimated in Table A-8 of that submittal that it can achieve 96% control at a cost of $330/ton. Please note that the GRE estimated cost to achieve 96% control is less than the $576/ton cost deemed "reasonable" by ND DOH to achieve 94% control.

It also appears that, not only is the ND DOH assuming that a 0.263 dv improvement is "negligible", it is using information—the relative differences in impacts among the control alternatives—that are not available to us. ND DOH should explain how it determined that upgrading the scrubbers to achieve 96% control is not economically reasonable, why a 0.263 dv improvement is "negligible", and where the modeling results cited in the ND DOH report are.

NO_x: Although GRE has proposed to meet the presumptive BART limits[2] with the existing controls LNB + SOFA, the Guidelines advise:

> "...the presumption does not limit the states' ability to consider whether a different level of control is appropriate in a particular case. If, upon examination of an individual EGU, a State determines that a different emission limit is appropriate based upon its analysis of the five factors, then the state may apply a more or less stringent limit."

Additional NO_x reductions could yield substantial benefits to the environment.

---

[1] The presumptive BART limits are 0.15 lb/mmBtu or 95% SO_2 reduction on a 30-day rolling average basis.

[2] The presumptive BART limit for these tangentially-fired boilers burning North Dakota lignite is 0.17 lb/mmBtu on a 30-day rolling average basis.

GRE has assumed that Selective Non-Catalytic Reduction (SNCR) could reduce NO_x emissions by 50% (2,678 tpy) at an annual cost of $23 million or $8,551/ton. However, GRE has assumed that residual ammonia in the fly ash would render the ash, which it currently sells, unsalable. On that assumption, GRE included "sunk costs" for its ash handling infrastructure, and annual costs that represent lost ash sales revenue. While it is inappropriate to include sunk costs in future decision-making, elimination of those sunk costs would only reduce the annual cost by about $1 million. However, the loss of ash sale revenue was counted as a $16 million cost out of the total annual operating cost of $21 million, so this issue must be resolved.

Great River Energy (GRE) Stanton Unit #1

Great River Energy (GRE) operates Stanton Unit #1 in Stanton, ND. Unit #1 is wall-fired with lignite and PRB sub-bituminous coal, and is rated at 188 MW (gross) output. Current emission control equipment consists of LNB and an ESP. Presumptive BART limits do not apply.

SO_2: ND DOH is proposing to limit emissions to 0.24 lb/mmBtu on a 30-day rolling average basis when the unit is burning lignite, and to 0.16 lb/mmBtu when burning Powder River Basin (PRB) sub-bituminous coal. ND DOH has determined that the incremental cost of installing and operating a 95%-efficient wet scrubber is excessive when compared to the cost of a 90%-efficient spray dryer. ND DOH also cites additional environmental impacts on water consumption and wastewater generation, plus the potential for pollution of the adjacent Missouri River. ND DOH contends that the additional benefits of greater SO_2 removal are more than offset by the additional costs and other environmental impacts.

ND DOH's SO_2 BART analyses in general, and its analysis of installing a new wet scrubber in particular, is of concern because it failed to evaluate any of the control options under the conditions upon which it based its final BART determination. Specifically, ND DOH based all of its cost and benefit calculations on current fuels—lignite with uncontrolled SO_2 emissions of 1.81 lb/mmBtu and PRB coal with uncontrolled emissions of 0.64 – 1.2 lb/mmBtu.[3] ND DOH determined that it is cost-effective to control SO_2 at $1,330 per ton when burning lignite and $2,006 per ton when burning PRB coal. However, in setting its proposed BART limits, it assumed that future uncontrolled SO_2 emissions would rise to 2.4 lb/mmBtu for lignite and 1.6 lb/mmBtu for PRB coal. A summary of the ND DOH analysis is presented below:

Summary of Stanton Unit #1 Spray Dryer Costs and Benefits as estimated by ND DOH

Fuel	ND lignite	PRB	Units	Notes
Uncontrolled SO2	1.81	1.20	lb/mmBtu	1
Uncontrolled SO2	9,376	6,216	tpy	1
Control efficiency	90%	90%		1
Controlled emissions	0.18	0.12	lb/mmBtu	1
Controlled emissions	938	622	tpy	1
Emissions Reduction	8,438	5,594	tpy	1
Annualized Cost	$ 11,220,000	$ 11,220,000	per year	1

---

[3] It appears that the actual BART determination was based upon the scenario with uncontrolled emissions at 1.2 lb/mmBtu.

Cost Effectiveness	$ 1,330	$ 2,006	per ton	1
Visibility Improvement (dv at Max Class I)	0.772		dv	2
Cost-Effectiveness ($/98th % dv at Max Class I)	$ 14,533,679		$/dv	3
Visibility Improvement (dv at Summed Class I)	1.511		dv	4
Cost-Effectiveness ($/98th % dv at Summed Class I)	$ 7,427,184		$/dv	5

(1) from ND DOH BART determination report
(2) Average 8th high visibility improvement at Theodore Roosevelt NP
(3) calculated
(4) Sum of average 8th high visibility improvements at Theodore Roosevelt NP and Lostwood NWR
(5) calculated

Because it is typically more cost-effective to control dirtier gas streams, we adjusted the cost analysis information provided by ND DOH and GRE to estimate the costs and benefits of scrubbing the higher sulfur fuels for which the BART limits were actually proposed.[4]

Summary of Stanton Unit #1 Wet Scrubber Costs and Benefits

Fuel	ND lignite	PRB	Units	Notes
Uncontrolled SO2	2.40	1.60	lb/mmBtu	1
Uncontrolled SO2	12,432	8,288	Tpy	2
Control efficiency	95%	95%		3
Controlled emissions	0.12	0.08	lb/mmBtu	4
Controlled emissions	622	414	Tpy	5
Emissions Reduction	11,811	7,874	Tpy	6
Annualized Cost	$ 13,911,294	$ 13,911,294	per year	7
Cost Effectiveness	$ 1,178	$ 1,767	per ton	8
Visibility Improvement (dv at Max Class I)	1.135	0.757	Dv	9
Cost-Effectiveness ($/98th % dv at Max Class I)	$ 12,256,349	$ 18,384,915	$/dv	10
Visibility Improvement (dv at Summed Class I)	2.114	1.410	Dv	11
Cost-Effectiveness ($/98th % dv at Summed Class I)	$ 6,579,077	$ 9,868,826	$/dv	12

(1) from ND DOH BART determination report
(2) Uncontrolled emissions from ND DOH BART determination report extrapolated for higher sulfur content
(3) from ND DOH BART determination report
(4) calculated
(5) calculated
(6) calculated
(7) Extra annual variable O&M cost from GRE report extrapolated for higher tons removed and added to Annualized Cost from ND DOH report
(8) calculated
(9) Average 8th high visibility improvement at Theodore Roosevelt NP plus additional visibility improvement extrapolated from GRE report for higher tons removed
(10) calculated
(11) Sum of average 8th high visibility improvements at Theodore Roosevelt NP and Lostwood NWR plus additional visibility improvement extrapolated from GRE report for higher tons removed
(12) calculated

It is cost-effective to achieve 95% control of SO_2 at $1,178/ton when burning lignite and $1,767/ton when burning PRB coal. On a $/ton basis, the 95% scrubbing option is more cost-effective than the less-efficient spray dryer alternative proposed by ND DOH.

---

[4] Electronic files containing our calculations are attached.

The fifth required element of a proper BART analysis is an evaluation of the impact of the options considered on visibility. Based upon data provided by GRE in Table 7-4 of its report, we have compiled a table showing the current average eighth-highest impacts on visibility at Theodore Roosevelt NP and Lostwood NWR.[5]

Stanton #1 **Baseline** **Data from GRE Table 7-4**

	2000	2001	2002	2000 - 2002
	8th High	8th High	8th High	Average 8th
Class I Area	(delta dv)	(delta dv)	(delta dv)	(delta dv)
TRNP	0.947	1.205	1.675	**1.276**
Lostwood	0.991	1.351	1.150	**1.164**
Total	1.938	2.556	2.825	**2.440**

Based upon data provided by ND DOH, we have compiled a table showing the average eighth-highest impacts on visibility at Theodore Roosevelt NP and Lostwood NWR, and the corresponding visibility improvements, when SO_2 emissions are reduced by 90%

Stanton #1 **90% Dry Scrubber** Data from ND DOH BART proposal

	2000	2001	2002	2000 - 2002
	8th High	8th High	8th High	Average 8th
Class I Area	(delta dv)	(delta dv)	(delta dv)	(delta dv)
TRNP	0.458	0.385	0.668	0.504
Lostwood	0.340	0.526	0.410	0.425
Total	0.798	0.911	1.078	0.929

Change	2000	2001	2002	2000 - 2002
	8th High	8th High	8th High	Average 8th
Class I Area	(delta dv)	(delta dv)	(delta dv)	(delta dv)
TRNP	0.489	0.820	1.007	**0.772**
Lostwood	0.651	0.825	0.740	**0.739**
Total	1.140	1.645	1.747	**1.511**

and by 95%.

Stanton #1 **95% Wet Scrubber** Data from ND DOH BART proposal

	2000	2001	2002	2000 - 2002
	8th High	8th High	8th High	Average 8th
Class I Area	(delta dv)	(delta dv)	(delta dv)	(delta dv)
TRNP	0.369	0.334	0.556	0.420
Lostwood	0.340	0.526	0.410	0.425

Total	1.229	1.696	1.859	**1.595**

---

[5] Because neither GRE nor ND DOH evaluated visibility impacts when burning PRB coal, only the lignite-firing results are available.

At 90% SO_2 control of the baseline condition, as proposed by ND DOH, visibility would improve by more than 0.7 dv at each Class I area, and by over 1.5 dv cumulatively. The cost of these improvements is about $15 million/dv at Theodore Roosevelt NP, and about $7 million/dv cumulatively.

At 95% SO_2 control of the baseline condition, as we have proposed, and with adjustments for the higher sulfur contents used by ND DOH in its BART determination, visibility would improve by about 1.0 dv at each Class I area, and by over 2.0 dv cumulatively.

Stanton #1	**95% Wet Scrubber on future higher sulfur lignite**			
Change	2000	2001	2002	2000 - 2002
	8th High	8th High	8th High	Average 8th
Class I Area	(delta dv)	(delta dv)	(delta dv)	(delta dv)
TRNP	0.766	1.155	1.484	**1.135**
Lostwood	0.863	1.094	0.981	**0.979**
Total	1.630	2.249	2.465	**2.114**

The cost of these improvements is about $12 million/dv at Theodore Roosevelt NP, and less than $7 million/dv cumulatively.

On a cost/ton and cost/deciview basis, wet scrubbing at 95% control is more cost-effective than the spray dryer at 90% control. While ND DOH cites the added environmental impacts of wet scrubbing, any costs associated with additional water use and wastewater treatment have been reflected in GRE's cost analyses, and thus have already been accounted. The concern about polluting the Missouri River, while valid, can be alleviated by proper design, operation, and maintenance by GRE.[6] Unless the local water supply is inadequate to support a wet scrubber, or unless there is some other insurmountable environmental factor that cannot be incorporated objectively into the analysis, we conclude that wet scrubbing at 95% control (or greater) is BART for Stanton #1.

NO_x: ND DOH has proposed that Stanton #1 meet the presumptive BART limits[7] with a combination of the existing LNB plus addition of Overfire Air and Selective Non-Catalytic Reduction (SNCR). While we continue to believe that Selective Catalytic Reduction (SCR) may also be a viable alternative, we commend ND DOH for the proposed reduction in NO_x emissions.

Basin Electric (Basin) Leland Olds Station

Basin Electric (Basin) operates Leland Olds Station (LOS) Units #1 & #2 in Stanton, ND. Both units are fired with ND lignite and PRB sub-bituminous coal. Unit #1 is wall-fired and is rated at 216 MW (gross) output; current emission control equipment consists of LNB and an ESP. Unit #2 is a cyclone furnace and is rated at 440 MW (gross) output; current emission control equipment consists of an ESP. Presumptive BART limits do not apply.

---

[6] This concern was not raised with respect to the proposed wet scrubbers at the Leland Olds Station, which is also located on the Missouri River.

[7] The presumptive BART limit for these wall-fired boilers is 0.29 lb/mmBtu when burning North Dakota lignite, and 0.23 lb/mmBtu when burning PRB sub-bituminous coal, on a 30-day rolling average basis.

Basin Electric (Basin) Leland Olds Unit #1

SO_2: ND DOH is proposing to limit SO_2 emissions to 0.15 lb/mmBtu **or** 95% reduction on a 30-day rolling average basis. We recommend 0.15 lb/mmBtu **and** 95% reduction on a 30-day rolling average basis because both of these levels are reasonable.

NO_x: ND DOH is proposing SNCR plus basic SOFA to limit NO_x emissions to 0.19 lb/mmBtu on a 30-day rolling average basis.[8] This is well below the 0.29 lb/mmBtu presumptive BART limit for this boiler. However, ND DOH has eliminated SCR from the five-factor analysis on the basis that it is technically infeasible when the unit is burning ND lignite. Based upon EPA's comments to ND DOH regarding the technical feasibility of applying SCR to lignite-fired boilers, ND DOH should proceed with the five-factor BART analysis.

Basin Electric (Basin) Leland Olds Unit #2

SO_2: ND DOH is proposing to limit SO_2 emissions to 0.15 lb/mmBtu or 95% removal on a 30-day rolling average basis. ND DOH has determined that, because the "most efficient control option" was selected for SO_2, no evaluation of costs or visibility impacts is necessary. We agree with EPA[9] that this approach does not meet the BART Guideline requirements for analysis and that a full five-factor analysis may find that even stricter controls would be cost-effective and/or provide greater visibility benefits.

NO_x: ND DOH is proposing application of SNCR and Advanced SOFA to limit NO_x emissions to 0.35 lb/mmBtu on a 30-day rolling average basis.

Presumptive BART for this large cyclone furnace is based upon application of SCR to achieve 0.10 lb/mmBtu on a 30-day rolling average basis. According to the BART Guidelines, "The use of SCRs at cyclone units burning bituminous coal, sub-bituminous coal, and ***lignite*** [emphasis added] should enable these units to cost-effectively meet NO_x rates of 0.10 lb/mmBtu."

ND DOH contends that SCR is not technically feasible for a boiler burning ND lignite. EPA has recently submitted expert testimony to ND DOH on the technical feasibility of SCR at Minnkota Power's Milton R. Young facility. We believe that EPA's analysis is valid and support EPA's conclusion that SCR is technically feasible. Because of the similarities among the cyclone furnaces at Milton R. Young and Leland Olds, we believe that the EPA conclusion is also applicable at LOS #2. ND DOH should evaluate SCR according to the remaining BART factors.

To provide a preliminary indication as to the possible economic feasibility of SCR, we applied the procedures described in Section 4, Chapter 2 of the OAQPS Control Cost Manual to the LOS #2 boiler. Using Basin's boiler and fuel information, we estimated an

---

[8] In its August 4, 2008, comments to ND DOH, EPA noted a discrepancy in the proposed NO_x limit that should be corrected.

[9] August 4, 2008, EPA comments to ND DOH.

Annualized Cost of $9.3 million, and produced a cost-effectiveness estimate of $854 per ton.[10]

Basin Electric Power--Leland Olds #2

Unit	#2	
Boiler Type	cyclone	ND DOH report
Fuel	ND lignite & PRB	ND DOH report
Rating (MW Gross) each	440	ND DOH report
Rating (mmBtu/hr)	5,130	ND DOH report
Current Emissions (tpy)	10,422	ND DOH report
Current Emissions (lb/mmBtu)	0.61	ND DOH report
NPS Cost-benefit Analysis		
Overall Control Efficiency	84%	calculated
Controlled emissions (tpy)	2,976	calculated
Controlled emissions (lb/mmBtu)	0.10	NPS analysis
Emission Reductions (tpy)	10,935	NPS analysis
Capital Cost	$ 43,869,929	NPS analysis
Capital Cost ($/kW)	$ 100	calculated
O&M Cost	$ 3,502,149	NPS analysis
Annualized Cost	$ 9,336,522	NPS analysis
Cost-Effectiveness ($/ton)	$ 854	NPS analysis

While these estimates do not include measures that may be required to address issues peculiar to the boiler and its fuels, they give an indication that application of SCR may be economically feasible and that ND DOH should proceed with the five-factor analysis for SCR at LOS #2.

Milton R. Young

Minnkota Power Cooperative (Minnkota) operates the Milton R. Young Station (MRYS) near Center, ND. According to ND DOH, Unit #1 is a cyclone furnace boiler fired with ND lignite from an adjacent mine and has a capacity[11] of 257 MW. Current emission control equipment consists of an Electrostatic Precipitator (ESP); Unit #2 is similar, but with a 477 MW capacity and a wet scrubber and ESP.

On April 24, 2006, EPA, DOJ, ND DOH, and Minnkota reached a settlement (Consent Decree = CD) of a New Source Review enforcement action. As a result, limits were set for Units #1 & #2 at MRYS for filterable PM and SO_2. A Best Available Control Technology (BACT) analysis for NO_x was required to be submitted by Minnkota within the following six months. That analysis was submitted along with the BART analysis and the BACT analysis became the basis for Minnkota's BART analysis. On August 4, 2008, EPA rejected that BACT analysis on the basis that Minnkota had not demonstrated that SCR was technically infeasible.

---

[10] Electronic files containing our calculations are attached.

[11] We understand that the actual capacity of both units at MRYS may still be unresolved and may bear upon the applicability of the presumptive BART limits.

We understand that EPA addressed a similar situation with respect to potential conflicts between BART and a CD at the Craig power plant in northwestern Colorado when it advised Colorado Air Pollution Control Division (APCD) that "We do not agree that the 2001 settlement and our approval of the settlement relieve APCD from meeting the requirements of our BART guidelines."[12] We understand that BART requirements must be satisfied independently of any existing CD.

Milton R. Young Unit #1

SO_2: Although Minnkota proposed addition of a wet scrubber at MRYS #1 to meet both 95% control and 0.15 lb/mmBtu on a 30-day rolling average basis, ND DOH has proposed only a 30-day average limit of 95% reduction. We believe that both limits are appropriate. ND DOH has determined that, because the "most efficient control option" was selected for SO_2, no evaluation of costs or visibility impacts is necessary. While this is a commendable level of additional control, we believe that this approach does not meet the BART Guidelines for proper analysis, and that a full five-factor analysis may find that even stricter controls would be cost-effective and/or provide greater visibility benefits.

PM: Because Minnkota is proposing a new wet scrubber for SO_2, ND DOH has also proposed to allow MRYS #1 to meet the 0.030 lb/mmBtu filterable PM limit set by the CD. We believe that a modern ESP should be capable of lower emissions, and that upgrading of the existing ESP deserves more attention.

NO_x: ND DOH proposes to reduce NO_x by applying SNCR+Advanced SOFA at 0.36 lb/mmBtu.

Presumptive BART for this large cyclone furnace is based upon application of SCR to achieve 0.10 lb/mmBtu on a 30-day rolling average basis. According to the BART Guidelines, "The use of SCRs at cyclone units burning bituminous coal, sub-bituminous coal, and ***lignite*** [emphasis added] should enable these units to cost-effectively meet NO_x rates of 0.10 lb/mmBtu."

ND DOH contends that SCR is not technically feasible for a boiler burning ND lignite. EPA has recently submitted expert testimony to ND DOH on the technical feasibility of SCR at MRYS. We believe that EPA's analysis is valid and support EPA's conclusion that SCR is technically feasible. ND DOH should evaluate SCR according to the remaining BART factors.

To provide a preliminary indication as to the possible economic feasibility of SCR, we applied the procedures described in Section 4, Chapter 2 of the OAQPS Control Cost Manual to the MRYS #1 boiler. Using Minnkota's boiler and fuel information, we estimated an Annualized Cost of $6.7 million, and produced a cost-effectiveness estimate of $839 per ton.[13]

---

[12] July 19, 2007, letter from Callie Videtich, EPA Region 8, to Paul Tourangeau, CO APCD.

[13] Electronic files containing our calculations are attached.

Minnkota Power--MR Young #1 & #2 **rejected SCR**

Unit	#1	#2	
Boiler Type	cyclone	cyclone	ND DOH report
Fuel	ND lignite	ND lignite	ND DOH report
Rating (MW Gross) each	257	477	ND DOH report
Rating (mmBtu/hr)	3,200	6,300	ND DOH report
Current Emissions (tpy)	8,665	14,705	ND DOH report
Current Emissions (lb/mmBtu)	0.81	0.81	ND DOH report
NPS Cost-benefit Analysis			
Control Efficiency	87.7%	87.7%	calculated
Controlled emissions (tpy)	1,631	3,294	calculated
Controlled emissions (lb/mmBtu)	0.10	0.100	NPS analysis
Emission Reductions (tpy)	7,971	11,757	NPS analysis
Capital Cost	$ 23,925,181	$42,273,746	NPS analysis
Capital Cost ($/kW)	$ 93	$ 89	calculated
O&M Cost	$ 3,500,668	$ 5,456,674	NPS analysis
Annualized Cost	$ 6,688,370	$11,087,866	NPS analysis
Cost-Effectiveness ($/ton)	$ 839	$ 943	NPS analysis

While these estimates do not include measure that may be required to address issues peculiar to the boiler and its fuels, they give an indication that application of SCR may be economically feasible and that ND DOH should proceed with the five-factor analysis for SCR at MRYS#1.

Milton R. Young Unit #2

SO_2: ND DOH has proposed upgrading the existing wet scrubber to meet a 30-day average limit of 90% reduction and 0.15 lb/mmBtu, or achieve 95% reduction on a 30-day rolling average basis. We recommend that, because ND DOH has determined that both limits are reasonably achievable, MRYS #2 meet 95% reduction and 0.15 lb/mmBtu.

PM: The CD requires the existing ESP to meet a limit on filterable PM of 0.030 lb/mmBtu. We understand that, in spite of the CD, PM control is still an open issue with respect to both BACT and BART. We recommend that an evaluation of upgrading the existing ESP to meet 0.015 lb/mmBtu is therefore appropriate.

NO_x: ND DOH proposes to reduce NO_x by applying SNCR+Advanced SOFA at 0.35 lb/mmBtu. Our comments stated above for MRYS Unit #1 also apply to the NO_x BART determination for MRYS Unit #2. Once again, to provide a preliminary indication as to the possible economic feasibility of SCR, we applied the procedures described in the OAQPS Control Cost Manual to the MRYS #2 boiler. Using Minnkota's boiler and fuel information, we estimated an Annualized Cost of $11.1 million, and produced a cost-effectiveness estimate of $943 per ton. Because SCR may be economically feasible, ND DOH should proceed with the five-factor analysis for SCR at MRYS#2.

Response to 8/11/08 NPS BART Comments on Coal Creek (7/16/09)

Coal Creek SO_2. The August 11, 2008 NPS comments are summarized below followed by the Department responses.

1. NPS Comment: ND DOH should explain how it determined that upgrading the scrubbers to achieve 96% control is not economically reasonable.

   NDDH Response: The August 2006 BART Analysis to which the comment refers was the first of several versions of that document issued by GRE over a 16-month period. Subsequent versions revised previous information to reflect the best available assessment to that date. The final version was issued by GRE in December of 2007 and is the document associated with the Department's analysis. Although preliminary information from GRE indicated the possibility of modifying the existing scrubber for 96% control, they subsequently revised that to 94%.

   The Department's experience indicates that 96% control should only be expected for a unit combusting coal with a higher sulfur content typically found in Eastern coal. The Coal Creek scrubbers are nearly 30 years old and retrofitting them is not expected to achieve greater than 95% control. The Department BART determination and the Permit to Construct have been revised to require the modified wet scrubber to achieve the same level of SO_2 control efficiency as wet scrubber replacement: 95% (30-day rolling average) on the inlet SO_2 concentration to the scrubber or 0.15 lb/10^6 Btu (30-day rolling average).

2. NPS Comment: ND DOH should explain why a 0.263 dV improvement is "negligible."

   NDDH Response: The Department BART determination and the Permit to Construct have been revised to require the modified wet scrubber to achieve the same level of SO_2 control efficiency as wet scrubber replacement: 95% (30-day rolling average) on the inlet SO_2 concentration to the scrubber or 0.15 lb/10^6 Btu (30-day rolling average). With this change, wet scrubber replacement would provide no improvement in visibility at any Class I area and would result in additional cost over wet scrubber modification ($24,987/ton incremental cost).

3. NPS Comment: ND DOH should explain where the modeling results cited in the ND DOH report are.

   NDDH Response: A previous NPS email dated 8/4/08 at 6:02 p.m. indicates this comment likely refers to modeling that would allow a comparison of the effects on visibility due to SO_2 reductions provided by wet scrubber replacement (95%), wet scrubber modification (then 94%, now 95%), and the addition of a spray dryer (90%). Pages 51-53 of the GRE analysis contain the modeling results of the impact on visibility associated with wet scrubber modification (at 94%) and wet scrubber replacement in conjunction with the most favorable NOx control options. Although the spray dryer option is not represented, that option would provide only 90% control while the scrubber modification and replacement options that are presented would provide 95% control. The Department does not require additional modeling details to determine that the spray dryer option at 90% control is not BART.

4. NPS Comment: GRE has assumed that residual ammonia in the fly ash would render the ash, which it currently sells, unsalable. This issue must be resolved.

   NDDH Response: In conjunction with previous comments in an NPS email dated 8/4/08 at 4:53 p.m., this comment appears to refer to a request for additional information to support the GRE position that employing SNCR technology may negatively affect fly ash sales due to ammonia slip. The attached GRE emails dated 8/8/08 at 3:19 p.m. and 8/17/08 at 2:22 p.m. provide additional information on this issue. The Department also considered a summary of a University of Kentucky study on the issue (attached) and has reached the following conclusions.

   - SCR and SNCR use at Coal Creek Station will likely result in ammonia in the fly ash.
   - The level of ammonia in the fly ash cannot be predicted with a reasonable certainty.
   - The maximum level of ammonia in fly ash that would still avoid negative impacts on the salability of the ash cannot be predicted.

   Therefore, the Department cannot determine with reasonable certainty that SCR or SNCR will not result in a level of ammonia in the ash that could reduce or eliminate future ash sales. Any regulator who determines that SCR or SNCR will not jeopardize ash sales would be obligated to present the evidence in support of that position. While another regulator might determine that even a small improvement in visibility is worth GRE taking the risk of lost ash sales, making a wrong decision on this one will inflict a significant financial penalty on GRE and send ash to a landfill instead of it being used beneficially. Having considered all of the information available, the NDDH BART determination on this matter remains unchanged and the Department considers the issue resolved.

FLM Comments on
Draft BART Assessments
Milton R. Young Station
and Leland Olds Station

Comment No.: 8
Commentor: FLMs
Affected Source: Leland Olds 2
Comment Summary: A 5 factor analysis is required even though the most efficient control technology is used.
Response: The BART Guideline Step 1, Paragraph 9, states "... if a source commits to a BART determination that consists of the most stringent controls available, then there is no need to complete the remaining analyses in this section." Basin had proposed the highest available control efficiency and lowest possible emission rate. Therefore, the other steps of a BART analysis were not required. The Department has now determined that SCR w/reheat is technically feasible. A visibility analysis of SCR vs SNCR has been included.

Comment No.: 22
Commentor: FLMs
Affected Source: Leland Olds Unit 1 & 2
Comment Summary: Recommend that the limit be written as 0.15 lb/10^6 Btu <u>and</u> 95% reduction.
Response: The BART Guideline lists the presumptive levels as 0.15 lb/10^6 Btu <u>or</u> 95% reduction. We believe applying both limits would be inappropriate. Basin Electric has justified a limit of 0.19 lb/10^6 Btu. The Department was able to reduce this limit to 0.15 lb/10^6 Btu by allowing Basin to comply with the 95% reduction requirement when higher sulfur coal is encountered.

Comment No.: 23
Commentor: FLMs
Affected Source: Leland Olds 1 & 2
Comment Summary: The FLMs believe SCR is technically feasible based on EPA's opinion.
Response: The Department believes high dust SCR is not technically feasible due to catalyst poisoning by sodium and potassium. A detailed examination of this issue is found in Appendix B.5. The Department now believes low dust and tail end SCR are technically feasible for North Dakota lignite-fired power plants.

Comment No.: 25
Commentor: FLMs
Affected Source: General
Comment Summary: The FLMs think the benefits of burning "low cost" lignite should be considered in determining BART.
Response: The BART Guideline establishes the costs that are to be considered when determining BART. In general, the cost of fuel is not one of them and fuel switching is not required.

Comment No.: 26
Commentor: FLMs
Affected Source: General
Comment Summary: There is a fundamental problem with setting only a percent-reduction limit for SO_2. As the sulfur content rises, SO_2 emissions will rise.
Response: EPA recognized that as the sulfur content rose the presumptive limit of 0.15 lb/10^6 Btu could not be met at some sources. Therefore, EPA allowed a presumptive level of 95% control. If BART had to be set based on a lb/MMBtu basis only, then this lb/MMBtu limit must be based on the higher sulfur coal. There would be no difference when higher sulfur coal is burned but higher emissions could occur if only a lb/MMBtu is set and lower sulfur coal is burned.

Comment No.: 27
Commentor: FLMs
Affected Source: General
Comment Summary: Upgrading of the ESPs for particulate control should be evaluated.
Response: Each source has evaluated replacing the ESP with a new ESP or new baghouse. In every case, the replacement of the ESP provides an insignificant amount of visibility improvement. Upgrading the ESPs would provide less visibility improvement. Therefore, there is no reason to evaluate the upgrade.

Comment No.: 28
Commentor: FLMs
Affected Source: General
Comment Summary: The allowable PM emission rates should be reduced.
Response: Each source has justified 0.10 lb/10^6 Btu as BART using the 5 factors analysis. The Department has reduced the emission limit to 0.07 lb/10^6 Btu because it is the lowest limit that can be met on a continuous basis and represents better than BART after consideration of the 5 factors.

Comment No.: 29
Commentor: FLMs
Affected Source: General
Comment Summary: It appears the Department is making its BART determinations based primarily on the incremental cost.
Response: The BART determinations where made based on the 5 factors in the BART Guideline. The Guideline gives the Department discretion on the weight assigned to each factor. The Department has always used the incremental cost when determining BACT. For BART, incremental costs were considered also. The BART Guideline states “Also, the greater number of possible control options that exist, the more weight should be given to the incremental costs vs. average cost.” As suggested by the BART Guideline, the incremental cost was weighted most heavily in the economic evaluation; however, all 5 statutory factors were considered.

Comment No.: 30
Commentor: FLMs
Affected Source: General
Comment Summary: Cumulative effects on multiple Class I areas should be considered instead of the "average" effects.
Response: The BART guideline does not establish or require a cumulative type analysis. This would be a difficult analysis (results must be paired in time) and does not represent actual visibility improvement since the analysis only addresses the individual source and not all sources that affect visibility in the Class I area. The Department did review maximum impacts from BART alternatives as well as average results. Since the BART Guideline does not require a cumulative analysis, we believe it is unnecessary and of little value. We have also determined that the BART single source modeling grossly overpredicts the amount of visibility improvement. Any combining of Class I areas using a cumulative effect would make the results even worse.

Comment No.: 31
Commentor: FLMs
Affected Source: M.R. Young 1
Comment Summary: Both a 0.15 lb/10^6 Btu and 95% reduction BART limit is appropriate.
Response: Based on future coal sulfur contents, Minnkota may not be able to comply with the 0.15 lb/10^6 Btu emission limit. Therefore, the 95% reduction only is appropriate and consistent with the BART Guideline.

Comment No.: 32
Commentor: FLMs
Affected Source: M.R. Young 1
Comment Summary: The SO_2 analysis does not address the 5 factors.
Response: Since Minnkota has selected the most efficient technology operating at the highest continuous efficiency, a 5 factor analysis is not required per the BART Guideline. Visibility modeling results which show the improvement have been provided.

Comment No.: 33
Commentor: FLMs
Affected Source: M.R. Young 1
Comment Summary: A lower emission limit for PM should be established.
Response: The BART analysis submitted by Minnkota justified 0.10 lb/10^6 Btu as BART based on the 5 statutory factors. Since the Consent Decree requires a limit of 0.03 lb/10^6 Btu, this rate was established as BART.

Comment No.: 34
Commentor: FLMs
Affected Source: M.R. Young 1
Comment Summary: Believe SCR is technically feasible.
Response: See response to Comment No. 23.

Comment No.: 35
Commentor: FLMs
Affected Source: M.R. Young 2
Comment Summary: Recommend SO_2 limit be 95% reductions and 0.15 lb/10^6 Btu.
Response: The Department determined that the 0.15 lb/10^6 Btu limit could not be met when higher sulfur coal is burned. Therefore, requiring both limits would be inappropriate.

Comment No.: 36
Commentor: FLMs
Affected Source: M.R. Young 2
Comment Summary: Recommend upgrading ESP to meet a 0.015 lb/10^6 Btu PM limit.
Response: Minnkota has justified a BART limit of 0.10 lb/10^6 Btu based on the 5 statutory factors. The limit of 0.03 lb/10^6 Btu is based on the Consent Decree.

Comment No.: 37
Commentor: FLMs
Affected Source: M.R. Young 2
Comment Summary: Believe SCR is technically feasible.
Response: See response to Comment No. 23.

Response to August 11, 2008 FLM BART Comments for Stanton Unit 1

The FLMs comments relating to the BART determination for Stanton Unit 1 are summarized below:

Comment #1:

The FLMs are concerned that the economic analysis was based on low uncontrolled SO_2 emissions while the BART emission limit was based on unreasonably high SO_2 emissions.

Response to Comment #1:

The Department's economic analyses were based on uncontrolled annual SO_2 emissions of 1.81 lb/million Btu for lignite and 1.2 lb/million Btu for PRB coal. The proposed BART emission limits for SO_2 are based on a 30-day rolling average (as opposed to an annual average) with 90% reduction and also includes emissions from startups, shutdowns and malfunctions. Based upon historical SO_2 emissions data for spray dryers and fabric filters at facilities burning North Dakota lignite, we have determined that an increase of 33% is warranted to adjust from an annual average SO_2 emission rate to a 30-day rolling average emission rate. The discussion regarding potential SO_2 emission rates as high as 2.4 lb/million Btu for lignite and 1.6 lb/million Btu for PRB coal was intended to show that higher sulfur coal could be encountered (see Appendix E, Sulfur Content Statistical Analysis, of the GRE BART Analysis).

Comment #2:

The FLMs contend that "On a $/ton basis, the 95% scrubbing option is more cost-effective than the less-efficient spray dryer alternative proposed by ND DOH" and "On a cost/ton and cost/deciview basis, wet scrubbing at 95% control is more cost-effective than the spray dryer at 90% control." Based upon the contention that wet scrubbing at 95% control is more cost-effective than a spray dryer at 90% control, the FLMs conclude that BART for Stanton #1 is a wet scrubber.

Response to Comment #2:

The FLMs chose to conduct the economic analysis for the wet scrubber based upon uncontrolled SO_2 emissions of 2.40 lb/million Btu for lignite and 1.60 lb/million Btu for PRB. The FLMs then compare the cost effectiveness for a wet scrubber (calculated at the 2.40 lb/million Btu and 1.60 lb/million Btu uncontrolled emission rates) to the cost effectiveness for a spray dryer calculated using uncontrolled SO_2 emission rates of 1.81 lb/million Btu for lignite and 1.20 lb/million Btu for PRB.

When comparing the cost effectiveness of different control technologies, it is necessary to use the same baseline uncontrolled emission rate for all control technologies. Since the FLMs failed to use the same baseline uncontrolled emission rates when calculating the cost effectiveness values for the wet scrubbing and spray dryer technologies, a comparison of the resulting cost effectiveness values is meaningless.

It should be noted that, since the annualized cost of a wet scrubber is estimated to be at least 15% greater than a spray dryer and only achieves a 5% greater emissions reduction, the FLMs contention that a wet scrubber is more cost effective than a spray dryer is not mathematically possible if the economic analysis is done correctly.

The Department correctly used the same baseline emission rate when calculating the cost effectiveness values for the SO_2 control technologies. When determining BART for SO_2, the Department also considered additional environmental considerations such as the additional water usage of a wet scrubber and the fact that a wet scrubber will remove a relatively small amount of SO_2 when compared to a dry scrubber (with a small corresponding visibility improvement).

Based upon the Department's analysis, the Department maintains the position that a spray dryer at 90% SO_2 control is more cost-effective than a wet scrubber at 95% SO_2 control. Considering the above factors, the Department has determined that BART is represented by the use of a spray dryer and fabric filter.

United States Department of Agriculture **Forest Service** **Superior National Forest**

Duluth, MN 55808-1122
Phone: (218) 626-4300
Fax: (218) 626-4398

File Code: 2580-2
Date: October 14, 2009

Mr. Terry L. O'Clair, P.E.
Director, Division of Air Quality
North Dakota Department of Health
918 E. Divide Ave.
Bismarck, ND 58501-1947

Dear Mr. O'Clair:

On August 26, 2009, the State of North Dakota submitted a draft implementation plan describing your proposal to improve air quality regional haze impacts at mandatory Class I areas across your region. We appreciate the opportunity to work closely with the State through the initial evaluation, development, and, now, subsequent review of this plan. Cooperative efforts such as these ensure that together we will continue to make progress toward the Clean Air Act's goal of natural visibility conditions at our Class I wilderness areas and parks.

This letter acknowledges that the U.S. Department of Agriculture Forest Service has received and conducted a substantive review of your proposed Regional Haze Rule implementation plan. Please note, however, that only the U.S. Environmental Protection Agency (EPA) can make a final determination about the document's completeness, and therefore, only the EPA has the ability to approve the document. Participation by the Forest Service in the State of North Dakota's administrative process does not waive any legal defenses or sovereignty rights it may have under the laws of the United States, including the Clean Air Act and its implementing regulations.

As outlined in a letter to North Dakota dated September 19, 2006, our review focused on eight basic content areas. The content areas reflect priorities for the Federal Land Manager agencies, and we have attached comments to this letter associated with these priorities. We look forward to your response required by 40 CFR 51.308(i)(3). For further information, please contact Eastern Region Air Resource Specialist Trent Wickman at (218) 626-4372 or Northern Region Air Resource Specialist Thomas Dzomba at (406) 329-3672.

Again, we appreciate the opportunity to work closely with the State of North Dakota. The Forest Service compliments you on your hard work and dedication to significant improvement in our nation's air quality values and visibility.

Sincerely,

/s/ Mark Hummel
MARK HUMMEL
Deputy Forest Supervisor

USDA Forest Service Technical Comments on the Regional Haze State Implementation Plan (RH SIP) for North Dakota

We appreciate the significant resources devoted by the State of North Dakota (ND) in developing a comprehensive, well organized, and easy to follow RH SIP. The projected emissions reductions in the SIP are an important first step toward improving visibility and other air quality related values at the affected Federal Class I areas (CIAs). We do have some concerns with some of the technical analyses and the some of the conclusions made in the RH SIP. These concerns are outlined below.

General Comments

1. We agree with previous comments by the National Park Service (NPS) that Theodore Roosevelt National Park should be treated as one Class I area, not three.

2. In a number of places in the RH SIP, ND characterizes its impact on its own class CIAs as "small." We note that this is a subjective term. Based on our review of RH SIPs from other states, we do not consider ND's percent contribution to visibility impairment in its own CIAs as being significantly different (i.e. smaller) than the other CIA owner states. For example ND's contribution to its CIAs is very similar to Minnesota's contribution to its CIAs. If ND feels this is not true, ND should include data to support this position. Nevertheless each State must demonstrate that it is obtaining "*its share of the emission reductions needed to meet the progress goal for the area*," per 40 CFR 51.308 (d) 3.

3. The RH SIP should explain how the reasonable progress goals (RPGs) will be revised once the RH SIPs from the neighboring contributing states are available.

4. We note that the State of Minnesota specifically asked ND to analyze the feasibility of reducing electrical generating unit (EGU) emissions in the state to less than 0.25 pounds per million Btu (lb/MMBtu) for sulfur dioxide (SO_2) and less than 0.22 lb/MMBtu for nitrogen oxides (NOx). We found a response from ND that outlined their disagreement with the premise of Minnesota's "ask." Additional information would be helpful comparing the emission level of ND's EGUs after the installation of controls prescribed under the Best Available Retrofit Technology (BART) and Reasonable Progress (RP) analyses.

5. We ask US EPA Regions 5 and 8 to arbitrate the disagreement between ND and Minnesota regarding Minnesota's "ask," as well as working with Canada on reducing emissions from sources in that country, especially the power plants mentioned by ND on page 53 of the RH SIP. This is especially relevant since power is sent across the US-Canada border.

General BART

6. We feel the decision to make Heskett Unit 2 not subject to BART is based on inappropriate modeling. Technical reasons were discussed on the call between ND and

the Federal Land Managers (FLMs) on September 22, 2009, including the use of using fine grid (1 km) modeling. Department of Interior modeling staff will provide more details. Please complete a full BART analysis for this unit. Alternatively, if Heskett is not found to be subject to BART it should be included in the State's reasonable progress analysis and a complete suite of possible control options examined in detail.

7. We would also like to note that the statement that Heskett is proposing a 70% SO_2 emission reduction is misleading. Baseline SO_2 emissions were reported as 2400 tons and the reduction project was reported to reduce emissions by 740 tons. This results in a 31% reduction.

8. EPA BART guidelines (Federal Register, July 6, 2005) on page 39170 directs the State to compare the 98 percentile days, pre-control versus post-control, so we disregarded the 90 percentile days presented in the RH SIP on Page 67.

9. On page 68 ND states "Though single-source modeling is specified in the BART guidance for determining degree of visibility improvement, it is clear that this modeling overstates the real single-source visibility impact." Please add a reference or basis for this statement. ND also adds "an observer's perception of visibility change is affected by the total loading of visibility-affecting species in the atmosphere." We agree. On clean days visibility can be impaired by a small amount of air pollution. That is why it is important to use clean days as a baseline from which to measure impairment from a source. Otherwise clean days are not protected.

10. In the BART section of the SIP ND appears to disregard the importance of EPA's presumptive BART limits. EPA considers these limits to be "generally cost effective" and in the case of scrubbers states, "We expect that scrubber technology will continue to improve and control costs continue to decline" (FR, 7/6/07, pg 39171).

SO_2 BART

11. MR Young Unit 2
    a. We feel the form of the emission limit needs to be reviewed. For example, the emission limit is specified as 95% control efficiency (CE). Therefore the pounds per million Btu (lb/MMBtu) limit should be 0.1 or else the effective limit becomes 0.15 lb/MMBtu which is 90% control. MR Young unit 1 is specified as having just a CE limit and no alternative lb/MMBtu. If Unit 1 can comply with just a CE limit we see no reason why Unit 2 can't also do the same.
    b. At the end of the BART analysis, ND changes the baseline emission level from 2.0 lb/MMBtu to 3.5 lb/MMBtu, which effectively raises the final BART limit. We feel the same baseline emission level should be used throughout the whole BART analysis, which includes calculating the costs per ton, as well as setting the limits.
12. Stanton
    a. It is unclear why this unit can't install a wet scrubber and meet the same limit as the Leland Olds Unit 1 (95% CE) which is a boiler of similar size, age, firing

type, and is also along the Missouri river. Please include a discussion of how the relevant BART factors are different for the two units. The costs for a wet scrubber at Stanton appear to be reasonable ($1480/ton).

b. Again, for this source, ND adjusted the baseline emission rate up for both fuels (i.e. from 1.8 to 2.4 lb/MMBtu for lignite and from 1.2 to 1.6 lb/MMBtu for sub-bituminous). As stated above we feel the baseline emission rate should be the same throughout the analysis. If the baseline emission rate were the same throughout the analysis, it would reduce the cost per ton presented, which already appears to be reasonable.

NOx BART

Over the past few years there has been much discussion regarding the application of SCR to lignite fired boilers. Due to the amount of time the EPA and the NPS have spent on this issue we believe they will respond most effectively and we will not offer specific comments on it other than to support the position of the NPS.

13. We would like to comment on an ancillary issue. ND states in the individual BART determinations, “The Department believes pilot scale testing would prove to be very beneficial in addressing the items of concern and provide a more detailed professionally reliable cost estimate. However, the BART process cannot mandate pilot testing be conducted to determine costs.” We agree and suggest that should a decision be made not to apply SCR with this SIP, additional pilot testing would be useful and encourage ND to include enforceable schedules in the long term strategy portion of its RH SIP. Minnesota took just such an approach in its RH SIP for the taconite industry which, like lignite fired power plants in North Dakota, had little data on NOx controls and is almost entirely in one state.

14. We note that Leland Olds Unit 2, and MR Young Units 1 and 2 do not meet presumptive BART, which as noted above is described by EPA as “generally cost effective.”

15. The startup/shutdown BART exemptions proposed for MR Young Units 1 and 2 are not necessary since the limit will be in the format of a 30 day rolling average. We have not seen such exemptions in BART determinations in other states. Four other BART units in ND are also using SNCR and are not asking for similar treatment. If these exemptions are allowed they should be severely limited by enforceable permit conditions, otherwise the integrity of the BART limit will be compromised.

Modeling – Chapter 8

We support comments from the Department of Interior agencies pertaining to this chapter.

Reasonable Progress

16. We applaud ND for the process it took to identify sources for which additional controls could be potentially applied under reasonable progress. Based on the Q/d metric, clearly Coyote and Antelope Valley Station (AVS) have visibility impacts that are on par with,

or exceed many of the subject to BART sources. These subject to BART sources were all prescribed to install additional SO_2 and NOx controls by ND in the draft SIP.

   a. SO_2 - Improvements to the existing spray dryer system should be included as an option, and costs determined, in the control technology analyses done for the AVS units. EPA states the following for existing flue gas desulfurization systems in their BART guidelines, "There are numerous scrubber enhancements available to upgrade the average removal efficiencies of all types of existing scrubber systems…" This is the approach taken by ND for the Coal Creek units and MR Young Unit 2.
   b. NOx - When comparing the emission rates from AVS and Coyote to the rest of the State's EGUs, AVS and Coyote would be the newest and the dirtiest. We note that ND states that moderate control options such as LNB/SNCR at 65% CE for AVS and ASOFA/SNCR at 55% CE at Coyote are reasonable (page 180 of the RH SIP).

   ND claims that the improvement in visibility from installing controls at AVS and Coyote is too small to require their installation. It is unclear which modeling method/protocol was used to produce the visibility results in Table 9.9, which makes their use problematic. Nevertheless AVS and Coyote are of the same general size, and located in the same general area, as the BART sources. Therefore we feel reductions at AVS and Coyote are equally important to those at the BART sources. ND required controls at the BART sources. The amount of reductions from AVS and Coyote are significant – in the range of 30,000 tons of combined NOx and SO_2, not including any additional SO_2 that could be reduced from upgrading the spray dryers at AVS. Please consider controls on AVS and Coyote such as LNB/SNCR at 65% CE for AVS and ASOFA/SNCR at 55% CE at Coyote.

17. Under the section on "Energy and non-air quality environmental impacts," we encourage ND to include the environmental and health *benefits* of installing additional controls. In general, the benefits of installing controls on EGUs far outweigh the costs.
    a. For example the report EC/R did for Midwest RPO (http://www.ladco.org/reports/rpo/consultation/index.php) shows that the health benefits of reducing SO_2 and NOx emissions under a region-wide SO2 and NOx control strategy are generally expected to outweigh the costs of control. These health benefits stem from the reduced ambient levels of PM and ozone which would result from the control of SO_2 and NOx. "When benefits in the entire modeling domain were considered, the estimated values of these benefits outweighed the projected costs of control by more than a factor of 10" (page 106). This does not include other environmental benefits of controls which are harder to quantify but nonetheless important (e.g. reduction in mercury deposition).
    b. In the original Clean Air Interstate Rule (CAIR), the range of annual *net* benefits (benefits less costs) to society were calculated to be approximately \$71.4 to \$60.4 billion in 2010 and \$98.5 to \$83.2 billion in 2015 (FR 5/12/05, pg 25305)

Other Comments

18. We do not support the method used to adjust the glidepath to account for Canadian emissions used in the RH SIP. We do support DOIs suggestion of using species-specific information provided by the Western Regional Air Partnership (WRAP).

19. We found no specific discussion in the draft SIP that considered contingency measures or procedures which could be triggered if the unexpected or unforeseen occurs. For example, if projected future emissions reductions do not materialize, or are distributed differently over an alternate geographic area, emission inventories could be found to be incorrect or flawed. Are there adaptive management strategies or increased review strategies which could be implemented in those situations? What will be done in five-years if North Dakota is over their projected emissions inventory? The SIP should provide a contingency plan to address these concerns.

20. We request that ND note that there is a linkage between the PSD program, its visibility impacts, and the need to protect the 20 percent best visibility days. An adequate relationship between the SIP and ND's PSD program also helps ensure that new sources not jeopardize the reasonable progress goals established by the RH SIP.

Department of the Interior Comments on the August 2009 draft of the North Dakota Regional Haze SIP (Plan) for Implementing Section 308 (40CFR51.308) of the Regional Haze Rules

Overall Comments

The air quality staffs of the National Park Service and U.S. Fish and Wildlife Service applaud the North Dakota Division of Air Quality (NDDAQ) on drafting a well-written and comprehensive Regional Haze Plan (Plan). It covers all of the policy areas of concern to us as outlined in our August 2006 letter to the States regarding development of regional haze plans.

In particular, we appreciate the comprehensive documentation of the visibility conditions and information base for each of the Class I areas. This information provides a firm foundation for tracking visibility conditions going forward as envisioned by the regional haze rule. We agree that the three major pollutants of concern for improving visibility in North Dakota are sulfates, nitrates, and organic particulates. We commend NDDAQ for the Plan's requirements to reduce approximately 90,000 tons per year of sulfur dioxide emissions. These reductions are a substantial step in making reasonable progress toward no human-caused impairment at Class I areas. We agree with concerns raised in the Plan that emissions controls in North Dakota alone are not sufficient to achieve visibility improvement goals set out in the 1999 Regional Haze Regulations. We look forward to working with NDDAQ, other States, and our Federal partners in a cooperative effort to achieve progress in reducing all human-caused impairment in a cost-effective manner.

The Department of the Interior noted in the enclosure to its letter to NDDAQ, dated February 29, 2008, regarding assessing air quality impacts from the Gascoyne Generating Station, the three units of Theodore Roosevelt National Park (NP) are one federal mandatory class I area under the Clean Air Act. We continue to take exception to the method NDDAQ used to calculate visibility impacts and assesses progress for that Class I area under various sections of the draft Plan by treating Theodore Roosevelt NP as three separate Class I areas.

We have serious concerns regarding the determination of the emissions limits representing Best Available Retrofit Technology (BART) for nitrogen oxide controls. In addition, we have serious concerns with the exemption of the Unit #2 at the R. M. Heskett Station from BART review, and the methods used for demonstrating reasonable progress at Class I areas affected by emissions from North Dakota sources.

Section Comments

Section One: Purpose / Legal Authority

No comments

Section Two: Overview

We disagree with the statement on page 8 claiming that North Dakota has four mandatory federal Class I areas as defined under the Clean Air Act. Based on the legislation establishing Theodore Roosevelt National Park and the Clean Air Act, North Dakota has two mandatory federal Class I areas (i.e., Theodore Roosevelt NP and the Lostwood Wilderness Area). The entire acreage of Theodore Roosevelt NP is one Class I area under the Clean Air Act, and should be treated as such for all protection purposes, such as assessing for increment consumption and calculating visibility impacts.

Section Three: Plan Development and Consultation

The plan addresses the State of Minnesota's request for NDDAQ to analyze the feasibility of reducing electrical generating unit (EGU) emissions in the North Dakota to less than 0.25 pounds per million Btu (lb/MMBtu) for sulfur dioxide (SO_2) and less than 0.22 lb/MMBtu for nitrogen oxides (NO_X). While NDDAQ listed reasons why it did not believe the State of Minnesota's request was supported by assessments of impact, we request that ND supply the emission rates established by the regional haze plan from EGUs across the State so we and the public can be informed of any differences between the request from Minnesota and the final requirements of the NDDAQ plan.

The U.S. Environmental Protection Agency (EPA) will need to review any discrepancy between the Minnesota regional haze plan and the North Dakota regional haze plan during its review and approval process. In addition, we agree with NDDAQ that the EPA should address the significant contribution of international emissions, particularly from power generation in Canada, in support of NDDAQ's efforts for reasonable progress.

Section Four: Monitoring Strategy and Other Implementation Plan Requirements

We note that the language in the footnote of Table 4.1 implies that the visibility monitoring conducted under the cooperative Inter-Agency Monitoring of Protected Visual Environments (IMPROVE) system at Theodore Roosevelt NP is covering more than one Class I area. While the monitoring is at one unit, it is representative of all three units of that one Class I area.

We appreciate NDDAQ's efforts to enhance monitoring of visibility with additional collection of data. We support the ongoing efforts to collect and periodically update state-wide inventories of pollutant emissions that may contribute to the visibility impairment noted on page 24 of the Plan.

Section Five: Baseline and Natural Conditions and Uniform Rate of Progress for North Dakota Class I Areas

As previously noted, we do not agree with the statement on page 30 that North Dakota has four distinct Class I areas. We do agree that the IMPROVE data collected at Theodore Roosevelt NP sufficiently tracks the long-term visibility conditions across the entire park and can be used for implementing the requirements of the regional haze rule.

Section Six: Sources of Visibility Impairment in North Dakota Class I Areas

We appreciate the presentation of the Western Regional Air Partnership (WRAP) assessment of sources of visibility impairment at the two North Dakota Class I areas. In particular, Table 6.6 is a useful summary of North Dakota's contribution to impairment listed by component of light extinction. This forms a baseline to compare projected conditions in the reasonable progress section of the Plan. We ask that NNDAQ clarify in the narrative that the sulfate and nitrate results are based on regional modeling using the CAMx-PSAT source apportionment tool, while the analyses of weighted emissions potential for organic carbon (OC), elemental carbon (EC), and particulate matter (PM) are based on emissions and residence time, not modeling. Figures 6.1, 6.2, 6.7, and 6.8 would be more informative if they also included 2018 results for sulfate and nitrate as is shown in the other figures for OC, EC, and PM.

Section Seven: Best Available Retrofit Technology (BART)

General Comments on BART

We appreciate this opportunity to comment upon the North Dakota Department of Health's (NDDAQ's) proposal for Best Available Retrofit Technology (BART) for the seven Electric Generating Units (EGUs) in North Dakota that it has identified as being subject to BART. We are impressed with the effort and expertise that went into this effort, and we are pleased that NDDAQ is proposing major reductions in the visibility-impairing pollutants sulfur dioxide (SO_2), and nitrogen oxides (NO_x). We are especially appreciative of the approximately 90,000 tons per year reduction in sulfur dioxide emissions from application of BART in the draft Plan. However, we believe that additional reductions can be achieved under the BART program. Based on our analyses summarized below and discussed in detail in the enclosed documents, we believe that additional reductions beyond those identified by NDDAQ are reasonable. Our comments below address the five-step BART process described by EPA's BART Guidelines and documented by NDDAQ.

As noted, we recognize that NDDAQ and the affected sources expended considerable effort in developing these analyses over several years and generated large amounts of useful information. However, it would be helpful, when NDDAQ advances this process into the public arena, if the NDDAQ BART determinations could provide more guidance as to the origins of the data used in their analyses. In our analyses of the data provided by NDDAQ and the sources, we generated several electronic files that we would be pleased to share with NDDAQ if those files could assist in providing a clearer understanding of this complex BART process.

Purpose of the BART Program

The core purpose of the BART program is to improve visibility in our Class I areas. BART is not necessarily the most cost-effective solution. Instead, BART represents a broad consideration of technical, economic, energy, and environmental (including visibility improvement) factors. We believe that it is essential to consider both the degree of visibility improvement in a given Class I area as well as the cumulative effects of improving visibility across all of the Class I areas affected.

Five-Step BART Process

Step 1: IDENTIFY AVAILABLE RETROFIT CONTROL TECHNOLOGIES
Except for Great River Energy's (GRE's) analysis for NO_x from Coal Creek, all of the other SO_2 and NO_x analyses included a reasonable suite of options.

We also have some general comments that apply to all of the PM_{10} analyses. We believe that the BART analyses are deficient in that they neither address upgrades to the existing Electrostatic Precipitators (ESPs) or propose limits that realistically reflect the capabilities of those existing ESPs, as well as the proposed new baghouses, to control filterable PM. EPA's BART Guidelines (Guidelines) advise:

- "...it is important to include control options that involve improvements to existing controls and not to limit the control options only to those measures that involve a complete replacement of control equipment."
- "...for retrofitting existing sources in addressing BART, you should consider ways to improve the performance of existing control devises, particularly when a control device is not achieving the level of control that other similar sources are achieving in practice with the same device. For example, you should consider requiring those sources with electrostatic precipitators (ESPs) performing below currently achievable levels to improve their performance."

Although all of these sources have ESPs in place, none of them except Stanton Unit #1 is currently achieving a level of performance equivalent to the 0.015 lb/mmBtu proposed for ESPs at sources such as Peabody's Thoroughbred and LG&E's Trimble County projects in Kentucky. Furthermore, EPA has recently issued a permit limiting the Desert Rock facility to 0.010 lb/mmBtu filterable PM_{10}, new baghouses are being permitted at 0.009 – 0.012 lb/mmBtu in Virginia (Virginia Hybrid Energy Center) and Wyoming (Dry Fork, WYGEN 3), and ND DOH proposed to permit the Gascoyne project at 0.012 lb/mmBtu. Instead, the limits on filterable PM_{10} proposed by NDDAQ are two – to – three times the emission rates measured by stack testing and cited by NDDAQ. While we understand that a certain "safety margin" must be allowed, we believe that the BART limits should be set to encourage continued good operation and maintenance of the pollution control equipment.

Step 2: ELIMINATE TECHNICALLY INFEASIBLE OPTIONS

This step was handled appropriately.

Step 3: EVALUATE EFFECTIVENESS OF REMAINING CONTROL TECHNOLOGIES

The ability of SCR to reduce emissions, as assumed by NDDAQ, was inconsistent and sometimes underestimated. For example, for the LNB/OFA+SCR option, GRE, Basin Electric Power Cooperative (BEPC), and NDDAQ sometimes assumed 0.07 lb/mmBtu for all averaging periods. However, for example, the WY Department of Environmental Quality has issued permits for new EGUs requiring that they meet 0.05 lb/mmBtu over averaging periods of 24-hours[1] and 30-days.[2] Furthermore, EPA's Clean Air Markets (CAM) data (Appendix A) and vendor guarantees[3] show that SCR can typically meet 0.05 lb/mmBtu (or lower) on an annual average basis. GRE, BEPC, and NDDAQ have not provided any documentation or justification to support the higher values used in their analyses. Our review of operating data (Appendix A) suggests that a NO_X limit of 0.06 lb/mmBtu is appropriate (with an adequate "safety-margin") for LNB/OFA+SCR for a 30-day rolling average, and 0.07 lb/mmBtu for a 24-hour limit and for modeling purposes, but a lower rate (e.g., 0.05 lb/mmBtu or lower) should be used for annual average and annual cost estimates. When the annual NO_x reductions are underestimated, the cost-effectiveness of the control option is negatively affected.

Step 4: EVALUATE IMPACTS AND DOCUMENT RESULTS

The cost of SCR was consistently overestimated. EPA's BART Guidelines recommend use of the OAQPS Control Cost Manual. Neither Minnkota Power Cooperative (Minnkota), GRE, BEPC, nor NDDAQ provided justification or documentation for their cost estimates. We were not provided with any vendor estimates or bids, and none used the recommended Control Cost Manual. This resulted in much-higher SCR costs than suggested by available literature (see Appendix B cost summaries) which shows SCR costs ranging from $50 - $267/kW. As recommended by the BART Guidelines, we applied the OAQPS Control Cost Manual to the EGUs and derived costs that fell within the Appendix B cost-survey range. As a result, we believe that capital and annual costs are overestimated by NDDAQ.

According to EPA's BART Guidelines, "the basis for equipment cost estimates should be documented, either with data supplied by an equipment vendor (i.e., budget estimates or bids) or by a referenced source (such as the OAQPS Control Cost Manual, Fifth Edition, February 1996, 453/B-96-001). In order to maintain and improve consistency, cost estimates should be based on the OAQPS Control Cost Manual, where possible. The Control Cost Manual addresses most control technologies in sufficient detail for a BART analysis. The cost analysis should also take into account any site-specific design or other conditions identified above that affect the cost of a particular BART technology option."

---

[1] Basin Electric—Dry Fork

[2] WYGEN3

[3] Minnesota Power has stated in its Taconite Harbor BART analysis that "The use of an SCR is expected to achieve a NO_X emission rate of 0.05 lb/mmBtu based on recent emission guarantees offered by SCR system suppliers."

EPA's belief that the Control Cost Manual should be the primary source for developing cost analyses that are transparent and consistent across the nation and provide a common means for assessing costs is further supported by this November 7, 2007, statement from EPA Region 8 to NDDAQ:

> The SO_2 and PM cost analyses were completed using the CUECost model. According to the BART Guidelines, in order to maintain and improve consistency, cost estimates should be based on the OAQPS Control Cost Manual. Therefore, these analyses should be revised to adhere to the Cost Manual methodology.

We are especially concerned about the lack of justification and support for the estimates of costs for reheating the exhaust gas streams to facilitate addition of "tail-end" SCR. Reheat costs are a critical issue affecting the economic feasibility of SCR, and, even in those cases where some data were presented (by GRE), it was still not adequate for us to be able to understand the assumptions that formed the bases for the natural gas usage estimates. Furthermore, we are concerned that the costs of catalyst, ammonia, electricity, and natural gas were inflated beyond what we typically see, or what is projected by the Energy Information Administration (EIA) with respect to future natural gas prices. Finally, we are concerned that this critical cost was simply scaled from a few examples and applied to other SCR analyses—we believe that it deserves individual analyses specific to each case.

Step 5: VISIBILITY IMPROVEMENT DETERMINATION

We believe that it is appropriate to consider both the degree of visibility improvement in a given Class I area as well as the cumulative effects of improving visibility across all of the Class I areas affected. It simply does not make sense to use the same metric to evaluate the effects of reducing emissions from a BART source that impacts only one Class I area as for a BART source that impacts multiple Class I areas. And, it does not make sense to evaluate impacts at one Class I area, while ignoring others that are similarly significantly impaired. If we look at only the most-impacted Class I area, we ignore that the other Class I areas are all suffering from impairment to visibility "caused"[4] by the BART source. It follows that, if emission from the BART source are reduced, the benefits will be spread well beyond only the most impacted Class I area, and this must be accounted for.

The BART Guidelines represent an attempt to create a workable approach to estimating visibility impairment. As such, they require several assumptions, simplifications, and shortcuts about when visibility is impaired in a Class I area, and how much impairment is occurring. The Guidelines do not attempt to address the geographic extent of the impairment, but assume that all Class I areas are created equal, and that there is no difference between widespread impacts in a large Class I area and isolated impacts in a small Class I area. To address the problem of geographic extent, we have been looking at the cumulative impacts of a source on all Class I areas affected, as well as the cumulative benefits from reducing emissions. While there are certainly more sophisticated

---

[4] EPA defines a source with an impact greater than one deciview as "causing" impairment.

approaches to this problem, we believe that this is the most practical, especially when considering the modeling techniques and information available.

We are concerned that NDDAQ has not adequately considered the visibility benefits of the control strategies it evaluated. In many cases, instead of evaluating a candidate BART strategy by determining the visibility improvement that would result from that particular strategy versus a "standard" baseline (e.g., the proposed SO_2 control options), the only analyses of visibility improvements were of the incremental differences between competing BART options. In most cases, were able to develop estimates of the actual improvements for a given strategy, but that was a very difficult process that required many assumptions and extrapolations that fail the test of "transparency."

The State's BART protocol was developed and approved by EPA Region 8 several years ago. Although we honor approved protocols from that time period, our modeling results indicate that use of current methods produces estimates of visibility impairment and improvement that are usually greater than the estimates provided by NDDAQ and the BART sources. For example, we evaluated the impacts of emissions from Leland Olds Station (LOS) Unit #2 using both the EPA-recommended Pasquill-Gifford (P-G) atmospheric stability approach and the turbulence-based approach used in ND. We first estimated the impacts from baseline emissions, but included condensable PM_{10} emissions using estimates derived from EPA's Compilation of Air Pollutant Emission Factors (AP-42). Next, we established a new "baseline" based upon emissions from LOS #2 after application of the proposed wet scrubber. Finally, we modeled the options in which Selective Non-Catalytic Reduction (SNCR) and SCR were added to the wet scrubber and compared each of those results to the "scrubber-only" results. We found that our modeling results (see Appendix C) consistently predicted significantly higher impacts and that the benefits of reducing NO_x were also substantially higher (by as much as a factor of two for addition of SCR to LOS #2). This has major implications for a program aimed at improving visibility.

BART DETERMINATIONS

It appears to be more beneficial to reduce NO_x than to reduce SO_2 in this cool climate. However, by placing more emphasis upon cost-per-ton ($/ton) of pollutants removed than on visibility improvement, the advantages of reducing NO_x versus SO_2 are overlooked if both are measured with the same $/ton yardstick. For this reason, we recommend that the primary emphasis should be placed upon the cost – per – deciview ($/dv) of improvement.

Compared to the typical control cost analysis in which estimates fall into the range of $2,000 - $10,000 per ton of pollutant removed, spending millions of dollars per deciview to improve visibility may appear extraordinarily expensive. However, our compilation[5] of BART analyses across the U.S. reveals that the **average cost per dv proposed by either**

---

[5] http://www.wrapair.org/forums/ssjf/bart.html

a state or a BART source is $9 - $20 million,[6] with a maximum of almost $50 million per dv proposed by Colorado at the Martin Drake power plant in Colorado Springs. A comparison of the cost/dv values resulting from NDDAQ's BART proposals shows that addition of Advanced Separated Over-Fire Air (ASOFA) and SNCR to LOS #1 would result in cost-effectiveness values of $27.3 million/dv at the most-impacted Class I area and $13.6 million/dv when the benefits to both Class I areas are considered. Likewise, the addition of combustion controls and SNCR at Stanton #1 would result in cost-effectiveness values of $33.1 - $41 million/dv at the most-impacted Class I area and $16.9 – $20.9 million/dv when the benefits to both Class I areas are considered. We suggest that NDDAQ should reconsider its other BART determinations in view of these cost-effectiveness values it has effectively accepted.

Another concern with the visibility analyses presented by NDDAQ is the over-emphasis on the incremental improvements to visibility resulting from SCR. NDDAQ calculated only the incremental improvement in visibility resulting from addition of some potential controls. Although incremental benefits are an appropriate consideration, they should not become the sole basis for a BART decision. NDDAQ should have presented the total visibility improvement that would result from a control option instead of presenting only the incremental improvement.

For several units, ND DOH is proposing alternative sulfur dioxide (SO_2) limits that are similar to the presumptive BART limits because they allow a source to choose between a limit in terms of pounds of emissions per million Btu of heat input, or percent reduction of that pollutant. While EPA presented its BART Guidelines for SO_2 in that format, we do not believe that it was EPA's intention to allow the source to choose the more favorable limit. By definition, BART represents the highest degree of control that meets the five-factor test. Where ND DOH has determined that a lb/mmBtu limit is reasonable, it should require that that limit be met. Similarly, where ND DOH has determined that a percent reduction limit is reasonable, it should require that that limit be met. If both limits are determined to be reasonable, then to allow the source to choose only one clearly does not represent the most stringent reasonable degree of control. Therefore, where ND DOH has proposed alternative limits, both should be required.

There is also a fundamental problem with setting only a percent-reduction limit on SO_2 emissions. If fuel sulfur content increases, emissions can increase correspondingly. Unless sulfur content is limited, or a cap is placed on mass emissions (e.g., lb/hr, tons/yr as proposed by Wyoming, for example), the actual amount of SO_2 emitted is unlimited.

In addition to an absence of any evaluation of upgrading the existing PM control equipment, it appears that ND DOH is not following EPA guidance to consider more stringent emission rates in setting permit limits:

> "If you find that a BART source has controls already in place which are the most stringent controls available (note that this means all possible improvements to any control

---

[6] For example, PacifiCorp has stated in its BART analysis for its Bridger Unit #2 that "The incremental cost effectiveness for Scenario 1 compared with the baseline for the Bridger WA, for example, is reasonable at $580,000 per day and $18.5 million per deciview."

> devices have been made), then it is not necessary to comprehensively complete each following step of the BART analysis in this section. As long as these most stringent controls available are made federally enforceable for the purpose of implementing BART for that source, you may skip the remaining analyses in this section."

We recommend that ND DOH establish permit limits that reflect the capabilities of the BART technology to control filterable PM.

Primary Conclusions & Recommendations

Our analyses of the information provided by NDDAQ lead us to the following preliminary conclusions and recommendations (as discussed in detail in the following documents):

- The loss of ash sales at Coal Creek is a critical, but unsupported, cost of adding SNCR or SCR. If ash sales are not adversely affected, addition of SNCR becomes a reasonable BART selection.
- Space constraints likely justify selection of the spray-dry/fabric filter option at Stanton #1.
- The cost of reheating stack gas to facilitate addition of SCR is a critical factor in the feasibility of that option and must be better-documented, along with better justification for the costs of SCR itself.
- The differing modeling approaches have a significant impact upon the visibility modeling results and should be evaluated and resolved.
- More emphasis should be placed upon the cumulative visibility benefits that could be derived from the BART program.
- SCR may become a more viable option when these issues of effectiveness, cost, and benefits are resolved.
- NDDAQ should consistently and transparently determine and apply an objective approach to its BART determinations.

Heskett Exemption

In Section 7.3.4, the Plan describes the steps taken that result in excluding the Montana Dakota Utilities R.M. Heskett Unit No. 2 from BART review. We are aware of the modeling protocol used by the WRAP and of a revised protocol developed from discussions between the U.S. EPA Region 8 staff and the NDDAQ staff regarding certain sources in the State. After the Heskett Unit No. 2 failed the exclusion modeling analysis under the revised North Dakota protocol, ENSR Corporation developed a third protocol for Heskett Unit No. 2. We have no record of receiving or reviewing the third modeling protocol conducted by ENSR Corporation for the Heskett facility. Our concerns with the work performed by ENSR Corporation center on the use of a 1 kilometer grid, and that the calculation for maximum impact separates Theodore Roosevelt NP into three separate Class I areas. Based on agreed-upon methods and its baseline emissions, we believe that Heskett Unit No. 2 is subject to BART requirements.

The draft Plan cites a reduction of Heskett Station's emissions of sulfur dioxide from a baseline of 2400 tons per year to a rate of 1660 tons per year within five years of Plan approval by the EPA. This reduction is a 31 percent reduction not the 70 percent reduction claimed in the draft Plan. This BART-like requirement is not based on assessing the full range of engineering options appropriate to Heskett Unit No. 2, nor is it consistent with the requirements of a voluntary reduction that would reduce the impact of the BART-eligible unit below the threshold that triggers BART requirements. To be accepted as a voluntary reduction, the source's emission limit would need to be in place upon submission of the Plan to the EPA.

Specific Comments on BART Determinations

Great River Energy (GRE) Coal Creek Units #1 & #2:

Great River Energy (GRE) operates Coal Creek Units #1 & #2 near Underwood, North Dakota. Both units are tangentially-fired with lignite from an adjacent mine and are rated at 550 MW (gross) output. Current emission control equipment consists of wet limestone scrubbers, Low-NO_x Burners (LNB) and Separated Overfire Air (SOFA), and Electrostatic Precipitators (ESPs). Although each unit has a capacity greater than 200 MW at a facility with a total capacity greater than 750 MW, presumptive BART limits only apply for nitrogen oxide (NO_x) because there are existing sulfur dioxide (SO_2) controls on both units at the facility.

Out of 1,228 power plants in EPA's Clean Air Markets (CAM) database in 2008, the Coal Creek plant ranked #104 for SO_2 at 23,142 tons and #101 for NO_x at 9,457 tons. According to modeling results provided by GRE, emissions from Coal Creek cause 2.9 dv of impairment in visibility at Theodore Roosevelt NP and 5.4 dv cumulatively when Lostwood WA is included. Without additional emission controls, SO_2 emissions are expected to almost double by 2019 due to deteriorating lignite quality (higher sulfur, lower heating value).

A. Sulfur Dioxide

Step 1: Identify All Available Technologies
We agree that NDDAQ has chosen a reasonable suite of options.

Step 2: Eliminate Technically Infeasible Options
We agree with NDDAQ's selection of technically feasible options.

Step 3: Evaluate Control Effectiveness of Each Remaining Control Technology
We agree with NDDAQ's estimates of control effectiveness.

Step 4: Evaluate Impacts and Document Results
While the proposed costs ($139/kW) for upgrading the scrubbers (and eliminating the flue gas by-pass) appear high when compared to similar projects in MN, ND and WY,[7] they have been accepted by both GRE and NDDAQ.

---

[7] Sherburne Country 1 MN, Bridger and WYODAK in WY, and MR Young in ND.

NDDAQ Estimates for Coal Creek Wet Scrubber Upgrade (each)

Total Capital Cost:	$ 76,222,700
Total Capital Cost $/kW):	$ 139
O&M Cost:	$ 2,090,296
Total Annual Cost:	$ 11,520,000
Cost per Ton	$ 555

Step 5: Evaluate Visibility Results

By comparing scenarios provided by GRE in which NO_x is constant but SO_2 changes, we have estimated that the proposed scrubber upgrades will each result in an approximately one dv improvement in visibility at Theodore Roosevelt NP and 1.9 dv cumulatively when Lostwood WA is included.

Determine BART

NDDAQ is proposing upgrading the existing wet scrubber to limit SO_2 emissions to 0.15 lb/mmBtu **or** 95% reduction on a 30-day rolling average basis. This results in cost-effectiveness values of $11.0 million per dv at Theodore Roosevelt NP and $5.9 million per dv cumulatively when Lostwood WA is included.

Scrubber Upgrade Cost-effectiveness

Annual Cost ($million)	$ 11.52
Visibility Improvement at TRNP (dv)	1.04
Cost-Effectiveness ($million/dv)	$ 11.06
Cumulative Visibility Improvement (dv)	1.94
Cost-Effectiveness ($million/dv)	$ 5.94

Because NDDAQ has proposed no absolute limits on emissions, the proposed BART limits would result in a 72% reduction in current SO_2 emissions on a lb/mmBtu basis and a 72% reduction on a tons-per-year basis.

Sulfur content of the coal was the primary constituent of concern because SO_2 emissions are directly related to the amount of sulfur in the coal and are not as related to equipment design. NDDAQ estimated that future delivered coal will have a maximum annual average sulfur content of approximately 1.10%.

Instead, we recommend 0.15 lb/mmBtu **and** 95% reduction on a 30-day rolling average basis because NDDAQ has determined that both of these levels are reasonable. Even if coal quality deteriorates to the anticipated worst-case (1.49 lb/mmBtu), 90% control would still meet the 0.15 lb/mmBtu limit.

B. Nitrogen Oxides

Step 1: Identify All Available Technologies
We believe that NDDAQ should have included a combination of combustion controls (e.g., Low-NO_X Burners, Over-Fire Air) coupled with Selective Catalytic Reduction (SCR) to its suite of options.

Step 2: Eliminate Technically Infeasible Options
Except as noted above, we agree with NDDAQ's selection of technically feasible options.

Step 3: Evaluate Control Effectiveness of Each Remaining Control Technology
Based on the 0.22 lb/mmBtu NO_X baseline emission rate, outlet emissions projected by NDDAQ for SCR at 0.07 lb/mmBtu represent only a 80% SCR control efficiency and a reduction of 4,286 tpy. (This is much lower than other analyses[8] in which NDDAQ has assumed 88% - 90% for SCR control effectiveness.) We believe that a combination of combustion control plus SCR can achieve 90% NO_x removal as opposed to the 80% estimated by NDDAQ for SCR alone.

Step 4: Evaluate Impacts and Document Results
NDDAQ estimated the following costs for LNB + SOFA:

NDDAQ Estimates for Coal Creek LNB+SOFA

Total Capital Cost:	$ 5,260,000
Total Capital Cost $/kW):	$ 10
O&M Cost:	$ 7,942
Total Annual Cost:	$ 660,000
Cost per Ton	$ 411

In its evaluations of SNCR and SCR, GRE included $13.75 million (per boiler) "sunk costs" for its ash handling infrastructure, and $14.4 million (per boiler) annual costs that represent lost ash sales revenue. It is inappropriate to include sunk costs in future decision-making.

If true, the loss of ash sale revenue and the consequent need to pay for ash disposal represent a major portion of the total $22.9 million annual operating cost for SNCR, and the total $37.1 million annual operating cost for SCR, so this issue becomes the critical factor affecting the cost-effectiveness of these technologies. However, NPS can find no examples of cases where ammonia contamination has resulted in lost ash sales, so we are presenting estimates that adjust the NDDAQ costs to eliminate the sunk costs as well as the costs associated with lost ash sales (as well as another $2 million per boiler annual cost for ash disposal). Our $1,072 cost was derived from applying the EPA Control Cost Manual. (Please see Appendix B.)

---

[8] Leland Olds #2, MR Young #1 & #2, Stanton #1

Coal Creek SNCR Cost Estimates

Cost	NDDAQ	NDDAQ (adj)	NPS
Total Capital Cost:	$ 19,909,069	$ 6,159,069	$ 6,862,904
Total Capital Cost $/kW):	$ 36	$ 11	$ 12
O&M Cost:	$ 21,231,102	$ 4,828,001	$ 2,265,878
Total Annual Cost:	$ 22,900,000	$ 6,496,899	$ 2,913,687
Cost per Ton	$ 8,551	$ 2,426	$ 1,072

NDDAQ has estimated a total annual cost for low-dust SCR with reheat at $56.2 million. Of that total, $19.2 million is a result of installing and operating a natural gas-fired gas reheating system to bring the flue gas back up to a temperature suitable for efficient SCR operation. The result of NDDAQ's assumptions is that SCR would cost over $13,000 per ton, which it deemed to be excessively costly.

Coal Creek SCR Cost Estimates

Cost	NDDAQ	NPS
Total Capital Cost:	$ 84,110,657	$ 41,718,972
Total Capital Cost $/kW):	$ 153	$ 76
O&M Cost:	$ 49,011,624	$ 11,389,572
Total Annual Cost:	$ 56,150,000	$ 15,327,547
Cost per Ton	$ 13,102	$ 3,722

NPS eliminated the sunk costs and the costs associated with lost ash sales and applied the EPA Control Cost Manual (Please see Appendix B.) to produce a much lower $3,722 per ton estimate for SCR.

Step 5: Evaluate Visibility Results

By comparing scenarios in which SO_2 is constant but NO_x changes, we have estimated that visibility improves at Lostwood WA 0.00006 dv per ton of NO_x removed, and 0.00012 dv/ton cumulatively. The visibility improvement values shown in the tables below are based upon those estimates.

Determine BART

NDDAQ is proposing LNB + SOFA at 0.17 lb/mmBtu on a 30-day rolling average basis.

LNB + SOFA Cost-effectiveness	NDDAQ
Annual Cost ($million)	$ 0.66
Visibility Improvement at Lostwood WA (dv)	0.10
Cost-Effectiveness ($million/dv)	$ 6.58
Cumulative Visibility Improvement (dv)	0.19
Cost-Effectiveness ($million/dv)	$ 3.52

NDDAQ rejected SNCR on the basis of excessive cost. However, when we adjusted the NDDAQ estimates to eliminate the effects of sunk costs and lost ash sales, the resulting cumulative cost-effectiveness of $20.1 million per dv becomes marginally cost-effective. NDDAQ should reevaluate SNCR in more depth.

SNCR Cost-effectiveness	**NDDAQ**	**NDDAQ (adj)**	**NPS**
Annual Cost ($million)	$ 22.90	$ 6.50	$ 2.91
Visibility Improvement at Lostwood WA (dv)	0.17	0.17	0.17
Cost-Effectiveness ($million/dv)	$ 137.02	$ 38.87	$ 17.18
Cumulative Visibility Improvement (dv)	0.31	0.31	0.32
Cost-Effectiveness ($million/dv)	$ 73.30	$ 20.80	$ 9.19

We estimate SNCR cost-effectiveness at $17.2 million per dv at Lostwood WA and $9.2 million per dv on a cumulative basis. We believe these costs are reasonable.

NDDAQ rejected SCR on the basis of excessive cost. When we adjusted the NDDAQ estimates to eliminate the effects of sunk costs and lost ash sales and applied the methods from the EPA Control Cost Manual, the results were still not cost-effective.

SCR cost-effectiveness	**NDDAQ**	**NPS**
Annual Cost ($million)	$ 56.15	$ 15.33
Visibility Improvement at Lostwood WA (dv)	0.27	0.26
Cost-Effectiveness ($million/dv)	$ 209.93	$ 59.64
Cumulative Visibility Improvement (dv)	0.50	0.48
Cost-Effectiveness ($million/dv)	$ 112.31	$ 31.91

Conclusions & Recommendations

- NDDAQ is proposing upgrading the existing wet scrubber to limit SO_2 emissions to 0.15 lb/mmBtu **or** 95% reduction on a 30-day rolling average basis. The proposed scrubber upgrades will each result in an approximately one dv improvement in visibility at Theodore Roosevelt NP and 1.9 dv cumulatively when Lostwood WA is included.
- We commend NDDAQ for the proposed new wet scrubber, but recommend that the limits require **both** 95% control **and** 0.15 lb/mmBtu, as well as specific caps on emissions.
- NDDAQ is proposing LNB + SOFA at 0.17 lb/mmBtu on a 30-day rolling average basis as BART for NO_X. As a result, visibility would improve by 0.10 dv at Lostwood and 0.19 dv cumulatively.
- NDDAQ has underestimated the effectiveness of SCR at only 80% control efficiency.
- NDDAQ has overestimated the costs of SNCR and SCR Many of the costs associated with SNCR and SCR presented by GRE and NDDAQ were not supported by GRE's documentation. Costs associated with lost ash sales and ash disposal were not adequately justified. More reliance should be placed upon use

of the EPA Control Cost Manual when the source fails, as GRE did, to provide sufficient supporting documentation of its costs. Our application of the EPA Control Cost Manual yielded much lower cost estimates for SNCR and SCR.

- NDDAQ has not adequately considered the visibility benefits of the control strategies it evaluated.
- NPS' analysis of addition of SNCR indicates that visibility would improve by 0.17 dv at Lostwood and 0.32 dv cumulatively. This yields a cost-effectiveness of $17.2 million per dv at Lostwood WA and $9.2 million per dv cumulatively when Theodore Roosevelt NP is included, which we believe to be reasonable based upon BART determinations and proposals we have seen nationwide to date.
- NPS' estimates for addition of SNCR show cost-effectiveness values below the $17 - $21 million per cumulative dv that NDDAQ accepted for adding SNCR at Stanton #1. Considering that the BART program is intended to improve visibility, it follows that any cost-effectiveness value below the costs per dv accepted by NDDAQ at Leland Olds #1 and Stanton should also be acceptable at Coal Creek.
- We conclude that SNCR is BART for control of NO_X emissions from GRE Coal Creek Units #1 and #2.

Great River Energy (GRE) Stanton Station Unit #1

Great River Energy (GRE) operates the 256 MW Stanton Station near Stanton, ND. The plant is located about 150 km from Theodore Roosevelt National Park NP, a Class I area administered by the National Park Service.[9] Out of 1,228 power plants in EPA's Clean Air Markets (CAM) database in 2008, the Stanton plant ranked #335 for sulfur dioxide (SO_2) at 2,873 tons and #324 for nitrogen oxides (NO_x) at 2,033 tons.

Stanton Unit #1

Unit #1 is a front-wall-fired boiler that burns sub-bituminous coal from the Powder River Basin (PRB) and local lignites. Unit #1 began operation in 1966 and is rated at 1,800 mmBtu/hr heat input. Unit #1 is equipped with Low-NO_x Burners (LNB) and an Electrostatic Precipitator (ESP) to control particulate matter (PM). Out of 3,558 units in EPA's CAM database in 2008, Stanton #1 ranked #667 for SO_2 at 2,726 tons and #696 for NO_x at 1,174 tons. According to modeling results provided by GRE, emissions from Stanton #1 cause 1.3 dv of impairment in visibility at Theodore Roosevelt NP and 2.4 dv cumulatively when Lostwood WA is included. Therefore, it is subject to Best Available Retrofit Technology (BART).

A. Sulfur Dioxide

NDDAQ has assumed that future uncontrolled SO_2 emissions may increase by 33% due to deteriorating coal quality.

Step 1: Identify All Available Technologies

We agree that NDDAQ has chosen a reasonable suite of options.

---

[9] The Lostwood National Wildlife Refuge, a Class I area administered by the U.S. Fish & Wildlife Service, is located about 150 km from the Stanton plant.

Step 2: Eliminate Technically Infeasible Options

We agree with NDDAQ's selection of technically feasible options. However, we also agree with NDDAQ that applying a wet scrubber at this site has so many adverse environmental consequences[10] that we will not consider that option further, and will confine our review to the Spray-Dryer/Fabric Filter (SD/FF) option.

Step 3: Evaluate Control Effectiveness of Each Remaining Control Technology

NDDAQ has estimated that a new SD/FF will reduce SO_2 emissions by 90% for both lignite and PRB coal combustion. We believe that higher control efficiency is warranted for the both the lignite and PRB sub-bituminous coal scenarios. For example, a SD/FF on 2.4 lb/mmBtu lignite or 1.6 lb/mmBtu PRB sub-bituminous coal should be capable of at least 93% control and achieve an emission limit of 0.09 lb/mmBtu on a 30-day rolling average basis.[11] Because the larger Stanton Unit #10 also located at this site is achieving less 0.06 lb/mmBtu on an annual basis (presumably burning PRB coal) using the same SD/FF technology proposed for Stanton #1, NDDAQ should explain why a newer installation of that technology at Stanton #1 cannot perform as well, at least on PRB coal.

Step 4: Evaluate Impacts and Document Results

The proposed cost ($423/kW) for adding the 90% efficient SD/FF appears reasonable. The result of NDDAQ's assumptions is that the new SD/FF would cost $1,330 per ton while burning lignite, and $2,006 per ton while burning PRB coal, which NDDAQ deemed reasonable. It is likely that increasing the SD/FF efficiency to achieve 0.09 lb/mmBtu would be even more cost-effective on a $/ton basis.

Stanton #1 SD/FF Cost Summary

	lignite	PRB
Total Capital Cost:	$ 79,514,000	$ 79,514,000
Total Capital Cost $/kW):	$ 423	$ 423
O&M Cost:	$ 4,071,674	
Total Annual Cost:	$ 11,220,000	$ 11,220,000
Cost per Ton	$ 1,330	$ 2,006

Step 5: Evaluate Visibility Results

Based upon data supplied by GRE and by NDDAQ, we have estimated that, when burning lignite, the proposed new 90% efficient SD/FF will result in an approximately 0.8 dv improvement in visibility at Theodore Roosevelt NP and 1.5 dv cumulatively when Lostwood WA is included. When burning PRB coal, the proposed new 90% efficient SD/FF will result in an approximately 0.5 dv improvement in visibility at Theodore Roosevelt NP and 1.0 dv cumulatively when Lostwood WA is included. Our review of NDDAQ visibility modeling yields a SO_2 control-effectiveness factor for the

---

[10] We are especially concerned about the problems associated with disposal of the wet scrubber sludge in this space-limited site adjacent to the Missouri River.

[11] Please see the entry in Appendix D for the permit issued by Wyoming to Black Hills Power for its WYGEN 3 project.

new SD/FF of 0.00009 dv/ton at Theodore Roosevelt NP and 0.00018 dv/ton cumulatively when Lostwood WA is included.[12]

Determine BART

NDDAQ is proposing addition of a new SD/FF to limit SO_2 emissions while burning lignite to 0.24 lb/mmBtu **or** 90% reduction on a 30-day rolling average basis. The proposed BART limits would result in an 86% reduction in current SO_2 emissions on a lb/mmBtu basis. However, because NDDAQ has proposed no absolute limits on emissions, unlimited operation at 0.24 lb/mmBtu could result in only a 77% reduction on a ton-per-year basis. If coal quality deteriorates to the anticipated worst-case (2.4 lb/mmBtu uncontrolled), the proposed BART limits would default to a 90% reduction on a lb/mmBtu basis and an 80% reduction in future SO_2 emissions on a ton/year basis.

While burning PRB sub-bituminous coal, NDDAQ is proposing 0.16 lb/mmBtu **or** 90% reduction on a 30-day rolling average basis. The proposed BART limits would result in a 91% reduction in current SO_2 emissions on a lb/mmBtu basis and an 85% reduction on a ton-per-year basis. If coal quality deteriorates to the anticipated worst-case (1.6 lb/mmBtu uncontrolled), the proposed BART limits would default to a 90% reduction on a lb/mmBtu basis and an 80% reduction in future SO_2 emissions on a ton/year basis.

Based upon NDDAQ's analysis, addition of the new SD/FF yields the cost-effectiveness values shown below, which we believe to be reasonable based upon BART determinations and proposals we have seen nationwide to date:

NDDAQ Estimates for SO_2 from burning	lignite	PRB
Annual Cost ($million)	$ 11.22	$ 11.22
Visibility Improvement at TRNP (dv)	0.77	0.51
Cost-Effectiveness ($million/dv)	$ 14.53	$ 21.92
Cumulative Visibility Improvement (dv)	1.51	1.00
Cost-Effectiveness ($million/dv)	$ 7.43	$ 11.20

We recommend limits of 0.09 lb/mmBtu **and** 93% reduction on a 30-day rolling average for both fuels based upon recent determination by other states for EGUs burning coals with similar uncontrolled emissions. Even if coal quality deteriorates to the anticipated worst-case 2.4 lb/mmBtu, 96% control would still meet the 0.0.09 lb/mmBtu limit. We also recommend short and long-term absolute (e.g., lb/hr, tpy) caps on emissions to insure that emissions will not increase greatly over time.

B. Nitrogen Oxides

Step 1: Identify All Available Technologies

We believe that NDDAQ should have included SOFA with tail-end SCR with reheat in its analysis.

---

[12] Our control-effectiveness factor is simply dv/ (tons per year reduced) and assumes a linear relationship for a given pollutant.

Step 2: Eliminate Technically Infeasible Options
Except as noted above, we agree with NDDAQ's selection of technically feasible options.

Step 3: Evaluate Control Effectiveness of Each Remaining Control Technology
NDDAQ's estimates of control effectiveness appear reasonable. For example, based on the 0.44 lb/mmBtu NO_X baseline emission rate, outlet emissions projected by NDDAQ for SCR at 0.044 lb/mmBtu represent 90% SCR control efficiency and a reduction of 1,929 tpy.

Step 4: Evaluate Impacts and Document Results
NDDAQ's estimates of costs for low-dust SCR with reheat are summarized below. In developing that estimate, NDDAQ relied upon GRE's estimates which included a total capital cost for SCR with reheat of $56.6 million or $301/kW. Because this exceeds the expected range of $50 - $267/kW presented in our Appendix B, we request that GRE/NDDAQ document and justify this estimate.

GRE/NDDAQ also estimate that $3.2 million of the $7.7 million annual cost is a result of installing and operating a natural gas-fired gas reheating system to bring the flue gas back up to a temperature suitable for efficient SCR operation.

The result of NDDAQ's assumptions is that SCR would cost $6,475 per ton when burning lignite, and $8,163 per ton when burning PRB coal, which it deemed to be excessively costly.

As recommended by the BART Guidelines, we applied the methods described in Section 4.2 of EPA's Control Cost Manual and estimated the costs, including GRE's reheat cost estimates, which we believe to be more representative, as summarized below:

Stanton #1 SCR on Lignite Cost Summary

	GRE/NDDAQ	NPS
Total Capital Cost:	$ 56,554,445	$ 18,986,724
Total Capital Cost $/kW):	$ 301	$ 101
O&M Cost:	$ 7,676,364	$ 4,311,537
Total Annual Cost:	$ 12,490,000	$ 6,103,749
Cost per Ton	$ 6,475	$ 3,288

Stanton #1 SCR on PRB Cost Summary

	GRE/NDDAQ	NPS
Total Capital Cost:	$ 56,554,445	$ 18,388,465
Total Capital Cost $/kW):	$ 301	$ 98
O&M Cost:	$ 7,676,364	$ 4,120,838
Total Annual Cost:	$ 12,490,000	$ 5,856,579
Cost per Ton	$ 8,163	$ 5,880

NDDAQ has estimated a total annual cost for its proposed LNB+OFA+SNCR at $3.0 million with cost-effectiveness of $3,052 per ton when burning lignite, and $3,778 per ton when burning PRB coal, which it deemed to be reasonable.

Step 5: Evaluate Visibility Results
Based upon data supplied by GRE and by NDDAQ, we have estimated that, when burning lignite, the proposed LNB+OFA+SNCR will result in an approximately 0.09 dv improvement in visibility at Theodore Roosevelt NP and 0.18 dv cumulatively when Lostwood WA is included. When burning PRB coal, the proposed LNB+OFA+SNCR will result in an approximately 0.07 dv improvement in visibility at Theodore Roosevelt NP and 0.14 dv cumulatively when Lostwood WA is included.

Contrary to the BART Guidelines, NDDAQ did not evaluate the visibility benefits of LNB+OFA+SCR However, our review of NDDAQ visibility modeling yields a NO_x control-effectiveness factor for basic LNB+OFA+SNCR of 0.0004 dv/ton at Theodore Roosevelt NP and 0.0008 dv/ton cumulatively when Lostwood WA is included. By applying the NO_x control-effectiveness factor to NDDAQ's estimated 1,929 tpy reduction from burning lignite with LNB+OFA+SCR with reheat, we have estimated that addition of LNB+OFA+SCR with reheat will result in an approximately 0.3 dv improvement in visibility at Theodore Roosevelt NP and 0.5 dv cumulatively when Lostwood WA is included. By applying the NO_x control-effectiveness factor to NDDAQ's estimated 1,530 tpy reduction from burning PRB coal with LNB+OFA+SCR with reheat, we have estimated that addition of LNB+OFA+SCR with reheat will result in an approximately 0.2 dv improvement in visibility at Theodore Roosevelt NP and 0.3 dv cumulatively when Lostwood WA is included.

Determine BART
NDDAQ is proposing addition of a LNB+OFA+SNCR to limit NO_x emissions when burning lignite to 0.29 lb/mmBtu, and 0.23 lb/mmBtu when burning PRB coal. Based upon NDDAQ's analysis, addition of the proposed LNB+OFA+SNCR yields a cost-effectiveness values shown below:

NDDAQ estimates for NOx from LNB+OFA+SNCR	lignite	PRB
Annual Cost ($million)	$ 3.00	$ 3.00
Visibility Improvement at TRNP (dv)	0.09	0.07
Cost-Effectiveness ($million/dv)	$ 33.09	$ 40.96
Cumulative Visibility Improvement (dv)	0.18	0.14
Cost-Effectiveness ($million/dv)	$ 16.92	$ 20.94

NDDAQ rejected tail-end SCR with reheat on the basis of excessive cost. NDDAQ's and NPS' analyses of addition of SCR with reheat yields the cost-effectiveness values shown below:

Estimates for NOx from **LNB+OFA+SCR burning**	**NDDAQ** **lignite**	**NPS** **lignite**	**NDDAQ** **PRB**	**NPS** **PRB**
Annual Cost ($million)	$ 12.49	$ 6.10	$ 12.49	$ 5.86
Visibility Improvement at TRNP (dv)	0.30	0.29	0.24	0.16
Cost-Effectiveness ($million/dv)	$ 41.31	$ 20.98	$ 52.09	$ 37.52
Cumulative Visibility Improvement (dv)	0.55	0.52	0.43	0.28
Cost-Effectiveness ($million/dv)	$ 22.90	$ 11.63	$ 28.88	$ 20.80

Based upon BART determinations and proposals we have seen nationwide to date, our cumulative cost-effectiveness values appear to be reasonable

Conclusions & Recommendations

- We agree with NDDAQ that applying a wet scrubber at this site has so many adverse environmental consequences that we will not consider that option further.
- NDDAQ proposed adding a new SD/FF to limit SO_2 emissions while burning lignite to 0.24 lb/mmBtu **or** 90% reduction on a 30-day rolling average basis. We recommend limits of 0.09 lb/mmBtu **and** 93% reduction on a 30-day rolling average for both fuels. Even if coal quality deteriorates, 96% control would still meet the 0.09 lb/mmBtu limit. We also recommend short and long-term absolute (e.g., lb/hr, tpy) caps on emissions to insure that emission will not increase greatly over time.
- NDDAQ is proposing addition of a LNB+OFA+SNCR to limit NO_x emissions when burning lignite to 0.29 lb/mmBtu, and 0.23 lb/mmBtu when burning PRB coal. NDDAQ has estimated a total annual cost at $3.0 million with cost-effectiveness of $3,052 per ton when burning lignite, and $3,778 per ton when burning PRB coal.
- When burning lignite, the proposed LNB+OFA+SNCR will result in an approximately 0.09 dv improvement in visibility at Theodore Roosevelt NP and 0.18 dv cumulatively. When burning PRB coal, the proposed LNB+OFA+SNCR will result in an approximately 0.07 dv improvement in visibility at Theodore Roosevelt NP and 0.14 dv cumulatively.
- NDDAQ estimates that SCR would cost $6,475 per ton when burning lignite, and $8,163 per ton when burning PRB coal, which it deemed to be excessively costly. NDDAQ has overestimated the costs associated with SCR. Many of the costs presented by GRE and NDDAQ were much higher than we have seen presented at similar facilities and were not supported by GRE's documentation. More reliance should be placed upon use of the EPA Control Cost Manual when the source fails, as did GRE, to provide sufficient supporting documentation of its costs. Our application of the Control Cost Manual yielded much lower cost estimates for SCR.
- When burning lignite, addition of LNB+OFA+SCR will result in an approximately 0.3 dv improvement in visibility at Theodore Roosevelt NP and 0.5 dv cumulatively when Lostwood WA is included. Cost-effectiveness is $11.6 million/dv - $20.1 million/dv, on a cumulative basis.

- When burning PRB coal, addition of LNB+OFA+SCR with reheat will result in an approximately 0.2 dv improvement in visibility at Theodore Roosevelt NP and 0.3 dv cumulatively when Lostwood WA is included. Cost-effectiveness is $20.1 - $28.9 million/dv, on a cumulative basis.
- We believe that SCR may represent BART, especially when the modeling issues identified in other reviews are resolved.

Basin Electric Power Cooperative (BEPC) Leland Olds Station (LOS) Units #1 & #2

Basin Electric Power Cooperative (BEPC) operates Leland Olds Station (LOS) Units #1 & #2 in Stanton, ND. Both units are fired with ND lignite and PRB sub-bituminous coal. Out of 1,228 power plants in EPA's Clean Air Markets (CAM) database in 2008, the Leland Olds plant ranked #12 for sulfur dioxide (SO_2) at 47,948 tons and #90 for nitrogen oxides (NO_x) at 11,065 tons. According to modeling results provided by BEPC, emissions from Leland Olds cause 5.6 dv of impairment in visibility at Theodore Roosevelt NP and 10.9 dv cumulatively when Lostwood WA is included. Without additional emission controls, SO_2 emissions are expected to more than double by 2019 due to deteriorating lignite quality (higher sulfur, lower heating value).[13]

Leland Olds Unit #1

Unit #1 is wall-fired and is rated at 216 MW (gross) output; current emission control equipment consists of LNB and ESP. Of 3,558 units in EPA's Clean Air Markets (CAM) database in 2008, LOS #1 ranked #95 for SO_2 at 17,926 tons and #90 for NO_x at 2,855 tons. According to modeling results provided by BEPC, emissions from LOS #1 cause 2.2 dv of impairment in visibility at Theodore Roosevelt NP and 4.1 dv cumulatively when Lostwood WA is included.

A. Sulfur Dioxide

Step 1: Identify All Available Technologies
We agree that NDDAQ has chosen a reasonable suite of options.

Step 2: Eliminate Technically Infeasible Options
We agree with NDDAQ's selection of technically feasible options.

Step 3: Evaluate Control Effectiveness of Each Remaining Control Technology

---

[13] BEPC has determined that historic rates are not representative of future maximum 24-hour emissions and has requested NDDAQ to allow the use of an alternative baseline. NDDAQ agreed to the alternative baseline. The alternative baseline and post-control scenarios are based upon various control technology emission reductions being applied to emissions from burning future coal at a heat input equal to the 100% of the boiler design capacity rating.

We agree with NDDAQ's estimates of control effectiveness on current lignite. However, we believe that higher control efficiency is warranted for the future lower quality (3.90 lb/mmBtu) lignite.

Step 4: Evaluate Impacts and Document Results
The proposed cost ($496/kW) for adding the 95%-efficient wet scrubber appears reasonable. The result of NDDAQ's assumptions is that the new wet scrubber would cost $586 per ton, which it deemed reasonable.

NDDAQ estimates for FGD on LOS #1 Cost Summary

Total Capital Cost:	$ 107,220,000
Total Capital Cost $/kW):	$ 496
O&M Cost:	$ 8,350,000
Total Annual Cost:	$ 19,310,000
Cost per Ton	$ 586

Step 5: Evaluate Visibility Results
NDDAQ did not evaluate the impact of the new wet scrubber versus the baseline condition. Therefore, we based our analysis on NDDAQ's modeling report for addition of a new scrubber to LOS #2. From that data we calculated a SO_2 control-effectiveness factor for the new wet scrubbers of 0.00004 dv/ton at Theodore Roosevelt NP and 0.00007 dv/ton cumulatively when Lostwood WA is included.[14] We have estimated that the proposed new wet scrubber will result in an approximately 1.2 dv improvement in visibility at Theodore Roosevelt NP and 2.4 dv cumulatively when Lostwood WA is included.

Determine BART
NDDAQ is proposing addition of a new wet scrubber to limit SO_2 emissions to 0.15 lb/mmBtu **or** 95% reduction on a 30-day rolling average basis. According to NDDAQ:

> Sulfur content of the coal was the primary constituent of concern because SO_2 emissions are directly related to the amount of sulfur in the coal and are not as related to equipment design. A forty year mining plan was analyzed to determine the future maximum annual sulfur content to be used in the BART analysis. The results indicated that future delivered coal will have a maximum annual average sulfur content of approximately 1.13% with a standard deviation of 0.12%. A 30-day rolling average SO_2 emission rate was calculated using the maximum sulfur content plus 1 standard deviation (i.e., 1.25% S).

Because NDDAQ has proposed no absolute limits on emissions, the proposed BART limits would result in a 92% reduction in current SO_2 emissions on a lb/mmBtu basis and a 90% reduction on a ton-per-year basis. If coal quality deteriorates to the anticipated worst-case (3.90 lb/mmBtu[15] uncontrolled), the proposed BART limits would default to a 95% reduction in future SO_2 emissions.

---

[14] Our control-effectiveness factor is simply dv/ (tons per year reduced) and assumes a linear relationship for a given pollutant.

[15] assumes unit-specific 37.4S SO_2 emission factor

Based upon NDDAQ's analysis, we estimate that addition of the new wet scrubber yields a cost-effectiveness of $15.9 million at Theodore Roosevelt NP and $8.0 million per dv cumulatively when Lostwood WA is included.

NDDAQ Cost-Effectiveness for SO_2 from	LOS #1
Annual Cost ($million)	$ 19.31
Visibility Improvement at TRNP (dv)	1.22
Cost-Effectiveness ($million/dv)	$ 15.89
Cumulative Visibility Improvement (dv)	2.43
Cost-Effectiveness ($million/dv)	$ 7.96

We recommend 0.15 lb/mmBtu **and** 95% reduction on a 30-day rolling average basis because NDDAQ has determined that both of these levels are reasonable. Even if coal quality deteriorates to the anticipated worst-case, 96% control would still meet the 0.15 lb/mmBtu limit.[16] We also recommend short and long-term absolute (e.g., lb/hr, tpy) caps on emissions to insure that emissions will not increase greatly over time.

B. Nitrogen Oxides

Step 1: Identify All Available Technologies

We believe that NDDAQ should have included a combination of combustion controls (e.g., Low-NO_X Burners, Separated Over-Fire Air) coupled with SCR to its suite of options.

Step 2: Eliminate Technically Infeasible Options

Except as noted above, we agree with NDDAQ's selection of technically feasible options.

Step 3: Evaluate Control Effectiveness of Each Remaining Control Technology

Based on the 0.285 lb/mmBtu NO_X baseline emission rate, outlet emissions projected by NDDAQ for SCR at 0.07 lb/mmBtu represent only a 75% SCR control efficiency and a reduction of 2,225 tpy. (This is much lower than other analyses[17] in which NDDAQ has assumed 88% - 90% for SCR control effectiveness.)

We believe that a combination of combustion controls (e.g., SOFA) plus SCR can achieve 0.05 lb/mmBtu (83% NO_x removal from the 0.29 lb/mmBtu 2000 – 2008 CAM average) as opposed to the 75% estimated by NDDAQ for SCR alone. EPA's CAM data[18] (Appendix A) and vendor guarantees[19] show that SCR can typically meet 0.05

---

[16] For example, West Virginia issued a permit on 3/01/04 to Longview Power to burn coal with an uncontrolled emission rate of 4.04 lb/mmBtu and meet a 24-hour average limit of 0.12 lb/mmBtu, which is equivalent to 97% control.

[17] Leland Olds #2, MR Young #1 & #2, Stanton #1

[18] We found at least 17 examples (Please see Appendix A., Table A.1.) of wall-fired boilers similar to LOS #1 that have been retrofitted with SCR and are achieving annual emission rates below 0.06 lb/mmBtu. We were able to find 2006 hourly emissions in EPA's CAM database for 14 of those EGUs, and charts showing those emissions are included in the wall-fired boilers portion of Appendix A. We believe that inspection of the data leads to the conclusion that these SCRs retrofit to eastern EGUs burning bituminous coal can

lb/mmBtu (or lower) on an annual average basis. BEPC has not provided any documentation or justification to support the higher values used in its analyses. Our review of operating data (Appendix A) suggests that a NO_X limit of 0.06 lb/mmBtu is appropriate (with a safety-margin) for LNB/OFA+SCR for a 30-day rolling average, and 0.07 lb/mmBtu for a 24-hour limit and for modeling purposes, but a lower rate (e.g., 0.05 lb/mmBtu or lower) should be used for annual average and annual cost estimates.

Step 4: Evaluate Impacts and Document Results
NDDAQ has estimated a total annual cost for its proposed basic SOFA with SNCR at $3.0 million with cost-effectiveness of $2,487 per ton, which it deemed to be reasonable.

NDDAQ estimates for Basic SOFA + SNCR on LOS #1 Cost Summary

Total Capital Cost:	$ 6,234,000
Total Capital Cost $/kW):	$ 29
O&M Cost:	$ 2,030,000
Total Annual Cost:	$ 3,099,000
Cost per Ton	$ 2,487

According to BEPC:[20]

> The capital costs to implement the various NO_x control technologies were largely estimated from unit output capital cost factors ($/kW) published in technical papers discussing those control technologies. In the cases with SNCR, preliminary vendor budgetary cost information was obtained and used in place of, or to adjust, the published unit output cost factors. The capital costs for combinations of NOx reduction technologies evaluated were typically estimated based upon simple arithmetic addition of the individual unit output capital cost factors for these technologies, multiplied by the nameplate capacity ratings of the steam-electric generating units at Leland Olds Station. These cost estimates were adjusted for inflation where appropriate (to 2005$), and are considered to be study grade, which is + or – 30% accuracy, or better.

For its LOS #1 SCR with reheat cost estimates, NDDAQ simply scaled the costs estimated by BEPC for the ASOFA+tail-end SCR with reheat option at LOS #2 based on the electrical output.[21] (Please see our discussion of the LOS #2 NO_x control cost estimates.) As a result, the $377 - $388/kW capital cost estimates actually used by BEPC are much higher than suggested by available information (Please see Appendix B cost summaries.) which suggests SCR costs ranging from $50 - $267/kW. BEPC has provided no justification for these extraordinarily high costs. Furthermore, neither BEPC nor NDDAQ provide any basis for their operating cost estimates which are roughly double those we estimated by applying the methods recommended by EPA in its Control Cost Manual. (Please see Appendix B.) NDDAQ has estimated a total annual cost for low-dust

---

typically reduce NO_x emissions by 90% and achieve 0.05 lb/mmBtu (or lower) on a 30-day rolling average basis during the eastern ozone season.

[19] Minnesota Power has stated in its Taconite Harbor BART analysis that "The use of an SCR is expected to achieve a NO_X emission rate of 0.05 lb/mmBtu based on recent emission guarantees offered by SCR system suppliers."

[20] from Burns & McDonnel 8/2006 **A2.1 Capital Cost Estimates for NO_x Controls**

[21] However, it is likely that this approach overestimated costs because of the higher cost of ASOFA at LOS #2 relative to SOFA at LOS #1.

SCR with reheat at $21.5 – 31.0 million. The result of NDDAQ's assumptions is that SCR would cost $9,600 - 14,000 per ton, which it deemed to be excessively costly.

NDDAQ estimates for SCR w Reheat on LOS #1 Cost Summary		
Cost	low	high
Total Capital Cost:	$ 81,392,727	$ 83,847,273
Total Capital Cost $/kW):	$ 377	$ 388
Catalyst ($/m^3)	$ 7,500	$ 7,500
Catalyst Life (hours)	$ 8,000	$ 4,000
Electricity ($/MWh)	$ 50	$ 50
Ammonia ($/ton)	$ 750	$ 750
Natural Gas ($/mcf)	$ 8	$ 12
O&M Cost:	$ 12,091,091	$ 19,867,091
Total Annual Cost:	$ 21,517,000	$ 31,011,000
Cost per Ton	$ 9,669	$ 13,936

In the absence of supporting documentation by BEPC or NDDAQ, as recommended by the BART Guidelines, we applied the methods described in Section 4.2 of EPA's Control Cost Manual and estimated a capital cost range of $101 - $142/kW which is much more consistent with available information. (Please see Appendix B.) We also estimated a total annual cost for basic SOFA+SCR with reheat at $6.5 – $15.0 million and $3,275 – $7,563 per ton.[22]

NPS estimates for SCR w Reheat on LOS #1 Cost Summary			
Cost	low	mid	high
Total Capital Cost:	$ 21,792,974	$ 21,792,974	$ 30,606,301
Total Capital Cost $/kW):	$ 101	$ 101	$ 142
Catalyst ($/m^3)	$ 3,000	$ 3,000	$ 7,500
Catalyst Life (hours)	$ 24,000	$ 8,000	$ 4,000
Electricity ($/MWh)	$ 38	$ 38	$ 50
Ammonia ($/ton)	$ 304	$ 304	$ 750
Natural Gas ($/mcf)	$ 8	$ 10	$ 12
O&M Cost:	$ 4,440,089	$ 5,634,987	$ 12,132,706
Total Annual Cost:	$ 6,512,534	$ 7,707,432	$ 15,037,898
Cost per Ton	$ 3,275	$ 3,876	$ 7,563

---

[22] The low end of this range, which we believe to be more representative of likely costs, is based upon an estimated 1,988 tpy reduction (@ 0.05 lb/mmBtu) and these operating costs estimated by NPS:

- Catalyst = $3,000/cubic meter (estimated by PacifiCorp in its BART analyses for its Wyoming EGUs) replaced every 24,000 hours[22]
- Electricity = $38/MWh (estimated by BEPC in its 8/2006 BART report)
- Ammonia = $304.45/ton (estimated by BEPC in its 8/2006 BART report)
- Natural gas = 56,455 mcf/hr @ $8/mcf from EIA forecast to 2030

Step 5: Evaluate Visibility Results
Based upon data supplied by BEPC and by NDDAQ, we have estimated that the proposed basic SOFA+SNCR will result in an approximately 0.1 dv improvement in visibility at Theodore Roosevelt NP and 0.2 dv cumulatively when Lostwood WA is included.

Contrary to the BART Guidelines, NDDAQ did not evaluate the visibility benefits of any of the technically-feasible options except for the proposed basic SOFA+SNCR. However, our review of NDDAQ visibility modeling yields a NO_x control-effectiveness factor for basic SOFA+SNCR of 0.00010 dv/ton at Theodore Roosevelt NP and 0.00019 dv/ton cumulatively when Lostwood WA is included. By applying the NO_x control-effectiveness factor to NDDAQ's estimated 2,225 tpy reduction from basic SOFA+SCR with reheat, we have estimated that addition of basic SOFA+SCR with reheat will result in an approximately 0.2 dv improvement in visibility at Theodore Roosevelt NP and 0.4 dv cumulatively when Lostwood WA is included.

Determine BART
Presumptive BART for this large wall-fired EGU burning lignite is 0.29 lb/mmBtu. NDDAQ is proposing that BART is an emission limit of 0.19 lb/10^6 Btu on a 30-day rolling average basis. Because NDDAQ has proposed no absolute limits on emissions, the proposed BART limits would result in a 30% reduction in current NO_x emissions on a lb/mmBtu basis and a 13% reduction on a ton-per-year basis.

Based upon NDDAQ's analysis, addition of the proposed basic SOFA+SNCR yields a cost-effectiveness of $25.6 million per dv at Theodore Roosevelt NP and $13.2 million per dv cumulatively when Lostwood WA is included.

NDDAQ Cost-Effectiveness Estimates for Basic SOFA+SNCR	**LOS #1**
Annual Cost ($million)	$ 3.10
Visibility Improvement at TRNP (dv)	0.11
Cost-Effectiveness ($million/dv)	$ 27.26
Cumulative Visibility Improvement (dv)	0.23
Cost-Effectiveness ($million/dv)	$ 13.59

NDDAQ rejected tail-end SCR with reheat on the basis of excessive cost. NDDAQ's analysis of addition of SCR with reheat yields a cost-effectiveness of $99.6 – $143.5 million per dv at Theodore Roosevelt NP and $51.2 – $73.8 million per dv cumulatively when Lostwood WA is included.

Cost-Effectiveness for SCR with Reheat on LOS Unit #1	NDDAQ		NPS		
	low	high	low	mid	high
Annual Cost ($million)	$ 21.52	$ 31.01	$ 6.80	$ 7.71	$ 15.04
Visibility Improvement at TRNP (dv)	0.20	0.20	0.62	0.62	0.61
Cost-Effectiveness ($million/dv)	$ 106.01	$ 152.78	$ 7.68	$ 9.16	$ 19.78
Cumulative Visibility Improvement (dv)	0.41	0.41	1.08	1.08	1.08
Cost-Effectiveness ($million/dv)	$ 52.85	$ 76.17	$ 4.37	$ 5.20	$ 11.24

NPS' analysis of addition of basic SOFA+SCR with reheat yields a cost-effectiveness of $7.7 – $19.8 million per dv at Theodore Roosevelt NP and $4.4 – $11.2 million per dv cumulatively when Lostwood WA is included.[23] We would normally consider costs above $20 million/dv to be above the average that most states/sources are proposing, but believe that these results warrant further analysis, as we will discuss in more detail with respect to LOS #2.

<u>Conclusions & Recommendations for LOS #1</u>

- NDDAQ is proposing addition of a new wet scrubber to limit SO_2 emissions to 0.15 lb/mmBtu **<u>or</u>** 95% reduction on a 30-day rolling average basis. We have estimated that the proposed new wet scrubber will result in an approximately 1.2 dv improvement in visibility at Theodore Roosevelt NP and 2.4 dv cumulatively when Lostwood WA is included. We commend NDDAQ for the proposed new wet scrubbers, but recommend that the limits require **<u>both</u>** 95% control **<u>and</u>** 0.15 lb/mmBtu, as well as specific caps on emissions.
- Presumptive NO_x BART for LOS #1 is 0.29 lb/mmBtu. NDDAQ is proposing that BART is an emission limit of 0.19 lb/10^6 Btu on a 30-day rolling average basis; this would improve visibility by 0.12 dv at Theodore Roosevelt NP and 0.24 dv cumulatively when Lostwood WA is included.
- Based upon NDDAQ's analysis, addition of the proposed basic SOFA+SNCR to LOS #1 yields a cost-effectiveness of $25.6 million per dv at Theodore Roosevelt NP and $13.2 million per dv cumulatively when Lostwood WA is included. NDDAQ has not adequately considered the visibility benefits of the control strategies it evaluated. NPS' analysis of addition of basic SOFA+SCR with reheat yields a cost-effectiveness of $12.6 – $32.3 million per dv cumulatively. We would normally consider costs above $20 million/dv to be above the average that most states/source are proposing, but believe that these results warrant further analysis, as we will discuss in more detail with respect to LOS #2.
- NDDAQ underestimated the effectiveness of adding SCR to LOS #1. Outlet emissions projected by NDDAQ for SCR at 0.07 lb/mmBtu represent only a 75% SCR control efficiency We believe that a combination of combustion controls (e.g., SOFA) plus SCR can achieve 0.05 lb/mmBtu, and represents BART.

---

[23] Our estimates were based upon the average NO_x emission rate in the CAM database for 2000 – 2008 and thus are significantly lower than the baseline emission estimated used by NDDAQ. As a consequence, our emission reductions are less, on a tpy basis, and our cost-effectiveness is negatively affected.

- NDDAQ overestimated the costs associated with adding SCR to LOS #1.Our application of the EPA Control Cost Manual yielded much lower cost estimates for SCR. Many of the costs associated with SCR presented by BEPC and NDDAQ were much higher than we have seen presented at similar facilities and were not supported by BEPC's documentation. More reliance should be placed upon use of the EPA Control Cost Manual when the source fails, as BEPC did for LOS, to provide sufficient supporting documentation of its costs.

Leland Olds Unit #2

Unit #2 is a cyclone furnace and is rated at 440 MW (gross) output; current emission control equipment consists of an ESP. Of 3,558 units in EPA's CAM database in 2008, the LOS #2 ranked #34 for SO_2 at 30,022 tons and #49 for NO_x at 8,210 tons. According to modeling results provided by BEPC, emissions from LOS #2 cause 3.4 dv of impairment in visibility at Theodore Roosevelt NP and 6.8 dv cumulatively when Lostwood WA is included.

However, NPS model results predict that emissions from LOS #2 cause 7.9 dv of impairment in visibility at Theodore Roosevelt NP and 13.5 dv cumulatively when Lostwood WA is included.[24]

A. Sulfur Dioxide

Step 1: Identify All Available Technologies

We agree that NDDAQ has chosen a reasonable suite of options.

Step 2: Eliminate Technically Infeasible Options

We agree with NDDAQ's selection of technically feasible options.

Step 3: Evaluate Control Effectiveness of Each Remaining Control Technology

We agree with NDDAQ's estimates of control effectiveness on current lignite. However, we believe that higher control efficiency is warranted for the future lower quality (4.04 lb/mmBtu) lignite.

Step 4: Evaluate Impacts and Document Results

The proposed costs ($335/kW) for adding the scrubbers appear reasonable. However, NDDAQ did not include any estimates of cost-effectiveness because it contends that it chose the most efficient option. We used NDDAQ's data to estimate that the new scrubber would cost $463/ton.

---

[24] Our analysis was based upon the design values presented by BEPC in Table 1.2-1 of its 8/06 BART report. BEPC has determined that historic rates are not representative of future maximum 24-hour emissions and has requested NDDAQ to allow the use of an alternative baseline. NDDAQ agreed to the alternative baseline. The alternative baseline and post-control scenarios are based upon various control technology emission reductions being applied to emissions from burning future coal at a heat input equal to the 100% of the boiler design capacity rating.

NDDAQ Estimates for FGD on LOS #2 Cost Summary

Total Capital Cost:	$ 147,600,000
Total Capital Cost $/kW):	$ 335
O&M Cost:	$ 14,210,000
Total Annual Cost:	$ 29,840,000
Cost per Ton	$ 463

Step 5: Evaluate Visibility Results
Based upon data supplied by BEPC and by NDDAQ, we have estimated that the proposed scrubber will result in an approximately 2.4 dv improvement in visibility at Theodore Roosevelt NP and 4.7 dv cumulatively when Lostwood WA is included. The NDDAQ visibility modeling yields a control-effectiveness factor for the new wet scrubber of 0.00004 dv/ton at Theodore Roosevelt NP and 0.00007 dv/ton cumulatively when Lostwood WA is included.

We re-modeled LOS #2 assuming that the new wet scrubber would reduce SO_2 emissions to 0.15 lb/mmBtu and held all other emissions to their baseline rates. Our results estimate that the scrubber would improve visibility by 5.6 dv at Theodore Roosevelt NP and 9.4 dv cumulatively when Lostwood WA is included. This yields a control-effectiveness factor for the new wet scrubber of 0.00009 dv/ton at Theodore Roosevelt NP and 0.00015 dv/ton cumulatively when Lostwood WA is included. We suggest that we investigate these major differences in modeling results further with NDDAQ.

Determine BART
NDDAQ is proposing to limit SO_2 emissions to 0.15 lb/mmBtu <u>or</u> a 95% reduction on a 30-day rolling average basis. As with Unit #1, sulfur content of the coal was the primary concern.

Because NDDAQ has proposed no absolute limits on emissions, the proposed BART limits would result in a 92% reduction in current SO_2 emissions on a lb/mmBtu basis and an 89% reduction on a ton-per-year basis. If coal quality deteriorates to the anticipated worst-case (4.04 lb/mmBtu[25] uncontrolled), the proposed BART limits would default to a 95% reduction in future SO_2 emissions.

Based upon NDDAQ's analysis, addition of the new wet scrubber yields a cost-effectiveness of $12.6 million, and $6.3 million per dv cumulatively when Lostwood WA is included.

---

[25] assumes unit-specific 38.7S SO_2 emission factor

NDDAQ Cost-Effectiveness for SO_2 from	LOS #2
Annual Cost ($million)	$ 29.84
Visibility Improvement at TRNP (dv)	2.38
Cost-Effectiveness ($million/dv)	$ 12.55
Cumulative Visibility Improvement (dv)	4.74
Cost-Effectiveness ($million/dv)	$ 6.29

We recommend 0.15 lb/mmBtu **and** 95% reduction on a 30-day rolling average basis because NDDAQ has determined that both of these levels are reasonable. Even if coal quality deteriorates to the anticipated worst-case, 96% control would still meet the 0.15 lb/mmBtu limit. We also recommend short and long-term absolute (e.g., lb/hr, tpy) caps on emissions to insure that emissions will not increase greatly over time.

B. Nitrogen Oxides

Step 1: Identify All Available Technologies

We agree that NDDAQ has chosen a reasonable suite of options.

Step 2: Eliminate Technically Infeasible Options

We agree with NDDAQ's selection of technically feasible options.

Step 3: Evaluate Control Effectiveness of Each Remaining Control Technology

Based on the 0.67 lb/mmBtu NO_X baseline emission rate, outlet emissions projected by NDDAQ for SCR at 0.07 lb/mmBtu represent a 90% SCR control efficiency and a reduction of 10,821 tpy. We suggest that, if ASOFSA can reduce emissions to 0.5 lb/mmBtu as estimated by NDDAQ, then addition of SCR at 90% as assumed by NDDAQ could bring emissions down to 0.05 lb/mmBtu.

Step 4: Evaluate Impacts and Document Results

NDDAQ has estimated a total annual cost for ASOFA with SNCR at $10.9 million with cost-effectiveness of $1,659 per ton, which it deemed to be reasonable.

NDDAQ Estimates for ASOFA + SNCR on LOS #2 Cost Summary

Total Capital Cost:	$ 16,800,000
Total Capital Cost $/kW):	$ 38
O&M Cost:	$ 7,830,000
Total Annual Cost:	$ 10,870,000
Cost per Ton	$ 1,659

BEPC submitted a separate analysis of ASOFA+tail-end SCR with reheat to NDDAQ in May 2009. (This became the basis for NDDAQ's scaling approach to its LOS #1 cost estimates.) BEPC based its capital cost estimates upon assumed ranges of costs for the control options evaluated. However, BEPC did not explain the origin of its cost ranges, and we believe that the ">$300/kW" estimate for ASOFA+tail-end SCR with reheat may be too high. In fact, the $377 - $388/kW capital cost estimates actually used by BEPC are much higher than suggested by available information (see Appendix B cost summaries) which suggests SCR costs ranging from $50 - $267/kW. BEPC has provided no justification for these extraordinarily high costs. Furthermore, neither BEPC nor NDDAQ provide any basis for their operating cost estimates which are roughly double those we estimated by applying the methods recommended in the Control Cost Manual. (Please see Appendix B.) NDDAQ has estimated a total annual cost for ASOFA+tail-end SCR with reheat at $43.8 – 63.2 million. The result is that ASOFA+tail-end SCR with reheat would cost over $4,000 - $5,800 per ton, which it deemed to be excessively costly.

NDDAQ Estimates for ASOFA + SCR with Reheat on LOS #2 Cost Summary		
	low	high
Total Capital Cost:	$ 165,800,000	$ 170,800,000
Total Capital Cost $/kW):	$ 377	$ 388
Catalyst ($/m^3)	$ 7,500	$ 7,500
Catalyst Life (hours)	8,000	4,000
Electricity ($/MWh)	$ 50.00	$ 50.00
Ammonia ($/ton)	$ 750.00	$ 750.00
Natural Gas ($/mcf)	$ 8.00	$ 12.00
O&M Cost:	$ 24,630,000	$ 40,470,000
Total Annual Cost:	$ 43,830,000	$ 63,170,000
Cost per Ton	$ 4,051	$ 5,838

In the absence of supporting documentation by BEPC or NDDAQ, as recommended by the BART Guidelines, we applied the methods described in the Control Cost Manual to the ASOFA+tail-end SCR with reheat option and estimated a capital cost range of $84 - $131/kW which is much more consistent with available literature which suggests SCR costs ranging from $50 - $267/kW. We applied the methods recommended by EPA and its Control Cost manual and estimated total annual costs for ASOFA+tail-end SCR with reheat at $13.8 – $28.7 million and $1,773 - $3,807 per ton.[26] (Please see Appendix B.)

---

[26] The low end of this range, which we believe to be more representative of likely costs, is based upon an estimated 7,530 tpy reduction (@ 0.06 lb/mmBtu)[26] and these operating costs estimated by NPS:

- Catalyst = $3,000/cubic meter (estimated by PacifiCorp in its BART analyses for its Wyoming EGUs) replaced every 24,000 hours
- Electricity = $38/MWh (estimated by BEPC in its 8/2006 BART report)
- Ammonia = $304.45/ton (estimated by BEPC in its 8/2006 BART report)
- Natural gas = 115,000 mcf/hr @ $8/mcf from EIA forecast to 2030

NPS Estimates for ASOFA + SCR with Reheat on LOS #2 Cost Summary			
	low	mid	high
Total Capital Cost:	$ 37,089,544	$ 37,089,544	$ 57,541,216
Total Capital Cost $/kW):	$ 84	$ 84	$ 131
Catalyst ($/m^3)	$ 3,000	$ 3,000	$ 7,500
Catalyst Life (hours)	24,000	8,000	4,000
Electricity ($/MWh)	$ 38.00	$ 38.00	$ 50.00
Ammonia ($/ton)	$ 304.45	$ 304.45	$ 750.00
Natural Gas ($/mcf)	$ 8.00	$ 10.00	$ 12.00
O&M Cost:	$ 8,918,956	$ 11,141,667	$ 22,307,414
Total Annual Cost:	$ 13,349,450	$ 15,572,161	$ 28,668,401
Cost per Ton	$ 1,773	$ 2,068	$ 3,807

Step 5: Evaluate Visibility Results

Based upon data supplied by BEPC and by NDDAQ, we have estimated that the proposed ASOFA + SNCR will result in an approximately 0.6 dv improvement in visibility at Theodore Roosevelt NP and 1.2 dv cumulatively when Lostwood WA is included. Our review of NDDAQ visibility modeling yields a NO_x control-effectiveness factor for the proposed combustion controls of 0.0004 dv/ton at Theodore Roosevelt NP and 0.0008 dv/ton cumulatively when Lostwood WA is included.

We re-modeled LOS #2 assuming that the proposed ASOFA + SNCR would reduce NO_X emissions to 0.35 lb/mmBtu. (We modeled SO_2 at 0.15 lb/mmBtu and held all other emissions to their baseline rates.) Our results estimate that ASOFA + SNCR would improve visibility by 1.1 dv at Theodore Roosevelt NP and 1.7 dv cumulatively when Lostwood WA is included.

Based upon data supplied by BEPC and by NDDAQ, we have estimated that addition of ASOFA+tail-end SCR with reheat will result in an approximately 1.1 dv improvement in visibility at Theodore Roosevelt NP and 2.0 dv cumulatively when Lostwood WA is included. Our review of NDDAQ visibility modeling for LOS #2 yields a NO_x control-effectiveness factor for the ASOFA+tail-end SCR with reheat option of 0.00010 dv/ton at Theodore Roosevelt NP and 0.00019 dv/ton cumulatively when Lostwood WA is included.

We re-modeled LOS #2 assuming that ASOFA + SCR would reduce NO_X emissions to 0.06 lb/mmBtu. (We modeled SO_2 at 0.15 lb/mmBtu and held all other emissions to their baseline rates.) Our results estimate that ASOFA + SCR would improve visibility by 2.3 dv at Theodore Roosevelt NP and 4.1 dv cumulatively when Lostwood WA is included. This yields a control-effectiveness factor for ASOFA + SNCR of 0.00031 dv/ton at Theodore Roosevelt NP and 0.00054 dv/ton cumulatively when Lostwood WA is included. Our higher control-effectiveness results show that we are estimating that removing a ton of NO_x has greater benefits than estimated by BEPC/NDDAQ.

Determine BART

Presumptive BART for this large cyclone furnace is based upon application of SCR to achieve 0.10 lb/mmBtu on a 30-day rolling average basis. According to the BART Guidelines, "The use of SCRs at cyclone units burning bituminous coal, sub-bituminous coal, and ***lignite*** [emphasis added] should enable these units to cost-effectively meet NO_x rates of 0.10 lb/mmBtu."

Instead of meeting the presumptive BART limit of 0.10 lb/mmBtu, NDDAQ is proposing application of SNCR and Advanced SOFA (ASOFA) to limit NO_x emissions to 0.35 lb/mmBtu on a 30-day rolling average basis. This equates to a cost-effectiveness of $17.1 million per dv at Theodore Roosevelt NP and $8.8 million per dv cumulatively when Lostwood WA is included.

NDDAQ Cost-Effectiveness for ASOFA+SNCR	**LOS #2**
Annual Cost ($million)	$ 10.87
Visibility Improvement at TRNP (dv)	0.64
Cost-Effectiveness ($million/dv)	$ 17.08
Cumulative Visibility Improvement (dv)	1.24
Cost-Effectiveness ($million/dv)	$ 8.78

Because NDDAQ has proposed no absolute limits on emissions, the proposed BART limits would result in a 43% reduction in current NO_x emissions on a lb/mmBtu basis and a 35% reduction on a ton-per-year basis.

NDDAQ rejected ASOFA+tail-end SCR with reheat on the basis of excessive cost. NDDAQ's analysis of addition of SCR with reheat yields a cost-effectiveness of $41.7 – $60.1 million per dv at Theodore Roosevelt NP and $21.4 – $30.9 million per dv cumulatively when Lostwood WA is included.

Cost-Effectiveness for SCR with Reheat on LOS #2	**NDDAQ**		**NPS**		
	low	**high**	**low**	**mid**	**high**
Annual Cost ($million)	$ 43.83	$ 63.17	$ 13.35	$ 15.57	$ 28.71
Visibility Improvement at TRNP (dv)	0.99	0.99	2.33	2.33	2.33
Cost-Effectiveness ($million/dv)	$ 44.41	$ 64.00	$ 3.83	$ 4.78	$ 9.59
Cumulative Visibility Improvement (dv)	1.98	1.98	4.10	4.10	4.10
Cost-Effectiveness ($million/dv)	$ 22.14	$ 31.91	$ 2.18	$ 2.72	$ 5.45

NPS' analysis of addition of basic ASOFA+SCR with reheat and using NDDAQ modeling results yields a cost-effectiveness of $3.8 – $9.6 million per dv at Theodore Roosevelt NP and $2.2 – $5.5 million per dv cumulatively when Lostwood WA is included.[27] We believe that our cost estimates indicate that addition of SCR with reheat is

---

[27] Our estimates were based upon the average NO_x emission rate in the CAM database for 2000 – 2008 and thus are significantly lower than the baseline emission estimated used by NDDAQ. As a consequence, our emission reductions are less, on a tpy basis, and our cost-effectiveness is negatively affected.

reasonable based upon BART determinations and proposals we have seen nationwide to date. We also believe that the great disparity between modeling results produced by BEPC/NDDAQ and NPS requires resolution.

Conclusions & Recommendations for LOS #2

- NDDAQ is proposing to limit SO_2 emissions to 0.15 lb/mmBtu **or** 95% reduction on a 30-day rolling average basis. We recommend 0.15 lb/mmBtu **and** 95% reduction on a 30-day rolling average basis.
- Based upon data supplied by NDDAQ, we have estimated that the proposed scrubber will result in an approximately 2.4 dv improvement in visibility at Theodore Roosevelt NP and 4.7 dv cumulatively when Lostwood WA is included.
- We re-modeled LOS #2 assuming that the new wet scrubber would reduce SO_2 emissions to 0.15 lb/mmBtu and held all other emissions to their baseline rates. Our results estimate that the scrubber would improve visibility by 5.6 dv at Theodore Roosevelt NP and 9.4 dv cumulatively when Lostwood WA is included.
- Instead of meeting the presumptive NO_x BART limit of 0.10 lb/mmBtu, NDDAQ is proposing application of SNCR and ASOFA to limit NO_x emissions to 0.35 lb/mmBtu on a 30-day rolling average basis.
- Based upon data supplied by BEPC and by NDDAQ, we have estimated that the proposed ASOFA + SNCR will result in an approximately 0.64 dv improvement in visibility at Theodore Roosevelt NP and 1.24 dv cumulatively when Lostwood WA is included.
- We agree with NDDAQ's estimates of control effectiveness, but suggest that, if ASOFSA can reduce emissions to 0.5 lb/mmBtu as estimated by NDDAQ, then addition of SCR at 90% as assumed by NDDAQ could bring emissions down to 0.05 lb/mmBtu.
- NDDAQ overestimated the costs associated with adding SCR to LOS #2.Our application of the EPA Control Cost Manual yielded much lower cost estimates for SCR. Many of the costs associated with SCR presented by BEPC and NDDAQ were much higher than we have seen presented at similar facilities and were not supported by BEPC's documentation. More reliance should be placed upon use of the EPA Control Cost Manual when the source fails, as BEPC did for LOS #2, to provide sufficient supporting documentation of its costs.
- We re-modeled LOS #2 and estimate that ASOFA + SCR would improve visibility by 2.3 dv at Theodore Roosevelt NP and 4.1 dv cumulatively when Lostwood WA is included. Our higher control-effectiveness results show that we are estimating that removing a ton of NO_x has greater benefits than estimated by BEPC/NDDAQ.
- NPS' analysis of addition of ASOFA+SCR with reheat and using NDDAQ modeling results yields a cost-effectiveness of \$4.0 – \$9.6 million per dv at Theodore Roosevelt NP and \$2.3 – \$5.5 million per dv cumulatively when Lostwood WA is included. We believe that our cost estimates indicate that addition of SCR with reheat is reasonable based upon BART determinations and proposals we have seen nationwide to date.
- The great disparity between modeling results produced by BEPC/NDDAQ and NPS requires resolution.

Minnkota Power Cooperative Milton R. Young Station Units #1 & #2

Minnkota Power Cooperative (Minnkota) operates Milton R. Young Station (MRYS) Units #1 and Square Butte Electric Cooperative (Square Butte) operates MRYS Unit #2 near Center, ND. MRYS is located within 300 km of two Class I areas, Lostwood National Wildlife Refuge Wilderness Area (WA) administered by the U.S. Fish & Wildlife Service and Theodore Roosevelt National Park (NP) administered by the National Park Service.

Both units are cyclone boilers fired with ND lignite. Of 1,228 power plants in EPA's Clean Air Markets (CAM) database in 2008, MRYS ranked #75 for sulfur dioxide (SO_2) at 28,910 tons and #41 for nitrogen oxides (NO_x) at 16,793 tons. According to modeling results provided by Minnkota, emissions from MRYS cause 5.8 dv of impairment in visibility at Theodore Roosevelt NP and 10.6 dv cumulatively when Lostwood WA is included.

On April 24, 2006, EPA, the U. S. Department of Justice, NDDAQ, and Minnkota reached a settlement (Consent Decree = CD) of a New Source Review enforcement action. A Best Available Control Technology (BACT) analysis was required to be submitted by Minnkota within the following six months. That BACT analysis was submitted along with the BART analysis and is the basis for the BART analysis. However, a revised BACT analysis is expected soon.

Minnkota claims that the MRYS facility is not a "750 MW power plant" and thus does not have to meet EPA's presumptive BART limits. This claim is based upon the nameplate capacities of the BART-eligible units at MRYS, but it avoids the issue that, by modifying those units, MRYS now substantially exceeds the nameplate capacities. If the presumptive BART limits were triggered only by nameplate capacity, a source such as MRYS would be able to increase its capacity without ever triggering presumptive BART. Because MRYS is capable of generating more than 750 MW, presumptive BART limits apply.

Milton R. Young Station Unit #1

MRYS Unit #1 is a lignite-fired cyclone boiler rated at 257 MW (gross) output; current emission control equipment consists of an ESP. Out of 3,558 units in EPA's CAM database in 2008, MRYS #1 ranked #82 for SO_2 at 19,608 tons and #50 for NO_x at 8,193 tons. According to modeling results provided by Minnkota, emissions from MRYS #1 cause 3.0 dv of impairment in visibility at Theodore Roosevelt NP and 5.3 dv cumulatively when Lostwood WA is included.

A. Sulfur Dioxide

Step 1: Identify All Available Technologies
We agree that NDDAQ has chosen a reasonable suite of options.

Step 2: Eliminate Technically Infeasible Options
We agree with NDDAQ's selection of technically feasible options.

Step 3: Evaluate Control Effectiveness of Each Remaining Control Technology
We agree with NDDAQ's estimates of control effectiveness.

Step 4: Evaluate Impacts and Document Results
The proposed cost ($435/kW) for adding the 95%-efficient wet scrubber appears reasonable. The result of NDDAQ's assumptions is that the new wet scrubber would cost $1,105 per ton, which it deemed reasonable.

NDDAQ estimates for FGD on MRYS #1 Cost Summary

Total Capital Cost:	$ 111,776,000
Total Capital Cost $/kW):	$ 435
O&M Cost:	$ 10,282,000
Total Annual Cost:	$ 22,584,000
Cost per Ton	$ 1,105

Step 5: Evaluate Visibility Results
Our analysis of Minnkota's modeling report determined that the proposed new wet scrubber will result in an approximately 1.8 dv improvement in visibility at Theodore Roosevelt NP and 3.2 dv cumulatively when Lostwood WA is included.

Determine BART
NDDAQ proposed adding a new wet scrubber that achieves 95% reduction on a 30-day rolling average basis.

Based upon NDDAQ's analysis, we estimate that addition of the new wet scrubber yields a cost-effectiveness of $12.3 million per dv at Theodore Roosevelt NP and $7.0 million per dv cumulatively when Lostwood WA is included.

NDDAQ Cost-Effectiveness for SO_2 from	**MRYS #1**
Annual Cost ($million)	$ 22.58
Visibility Improvement at TRNP (dv)	1.83
Cost-Effectiveness ($million/dv)	$ 12.33
Cumulative Visibility Improvement (dv)	3.19
Cost-Effectiveness ($million/dv)	$ 7.09

We recommend addition of short and long-term absolute (e.g., lb/hr, tpy) caps on emissions to insure that emissions will not increase greatly over time.

B. Nitrogen Oxides

Step 1: Identify All Available Technologies
We agree that NDDAQ has chosen a reasonable suite of options.

Step 2: Eliminate Technically Infeasible Options
We agree with NDDAQ's selection of technically feasible options.

Step 3: Evaluate Control Effectiveness of Each Remaining Control Technology
Based on the 0.849 lb/mmBtu NO_X baseline emission rate, outlet emissions projected by NDDAQ for SCR at 0.085 lb/mmBtu represent a 90% SCR control efficiency and a reduction of 8,129 tpy. We agree with NDDAQ's estimates of control effectiveness, but suggest that, if ASOFSA can reduce emissions to 0.513 lb/mmBtu as estimated by NDDAQ, then addition of SCR at 90% could bring emissions down to 0.05 lb/mmBtu.

Step 4: Evaluate Impacts and Document Results
NDDAQ has estimated a total annual cost for its proposed ASOFA with SNCR at $7.4 million with cost-effectiveness of $2,541 per ton, which it deemed to be reasonable.

NDDAQ Estimates for ASOFA + SNCR on MRYS #1

Total Capital Cost:	$ 8,113,000
Total Capital Cost $/kW):	$ 32
O&M Cost:	$ 5,417,000
Total Annual Cost:	$ 7,472,000
Cost per Ton	$ 2,541

For its MRYS #1 SCR cost estimates, NDDAQ scaled the costs estimated for the ASOFA+tail-end SCR with reheat option at Leland Olds Station (LOS) #2 based on the electrical output. (Please see our discussion of the LOS #2 NO_x cost estimates.) As a result, the $377 - $388/kW capital cost estimates used by NDDAQ are much higher than suggested by available information (Please see Appendix B.) which suggests SCR costs ranging from $50 - $267/kW. NDDAQ has provided no justification for these extraordinarily high costs. Furthermore, NDDAQ did not provide any basis for their operating cost estimates which are roughly double those we estimated by applying the methods recommended the Control Cost Manual. NDDAQ has estimated a total annual cost for SCR with reheat at $25.6 – 36.9 million. The result of NDDAQ's assumptions is that SCR would cost $3,100 – 4,600 per ton, which it deemed to be reasonable.

SCR on MRYS #1 Cost Summary	**NDDAQ**		**NPS**
	low	high	
Total Capital Cost:	$ -	$ -	$ 17,762,559
Total Capital Cost $/kW):	$ -	$ -	$ 69
Catalyst ($/m^3)	$ 7,500	$ 7,500	$ 3,000
Catalyst Life (hours)	$ 8,000	$ 4,000	$ 24,000
Electricity ($/MWh)	$ 50	$ 50	$ 38
Ammonia ($/ton)	$ 750	$ 750	$ 304
Natural Gas ($/mcf)	$ 8	$ 12	$ 8
O&M Cost:	$ -	$ -	$ 5,578,686
Total Annual Cost:	$ 25,600,000	$ 36,897,000	$ 9,744,345
Cost per Ton	$ 3,149	$ 4,539	$ 1,028

In the absence of supporting documentation by NDDAQ, as recommended by the BART Guidelines, we applied the methods described in the Control Cost Manual and estimated a capital cost of $69/kW which is much more consistent with available information. (Please see Appendix B.) We also estimated a total annual cost for ASOFA+SCR with reheat at $9.7 million and $1,028 per ton.

Step 5: Evaluate Visibility Results

Based upon data supplied by Minnkota and by NDDAQ, we have estimated that the proposed ASOFA+SNCR will result in an approximately 0.12 dv improvement in visibility at Theodore Roosevelt NP and 0.24 dv cumulatively when Lostwood WA is included.

Contrary to the BART Guidelines, NDDAQ did not evaluate the visibility benefits of any of the technically-feasible options except for the proposed ASOFA+SNCR. However, our review of NDDAQ visibility modeling yields a NO_x control-effectiveness factor for ASOFA+SNCR of 0.00020 dv/ton at Theodore Roosevelt NP and 0.00032 dv/ton cumulatively when Lostwood WA is included. By applying the NO_x control-effectiveness factor to NDDAQ's estimated 8,129 tpy reduction from ASOFA+SCR with reheat, we have estimated that addition of ASOFA+SCR with reheat will result in an approximately 1.7 dv improvement in visibility at Theodore Roosevelt NP and 2.6 dv cumulatively when Lostwood WA is included.

Determine BART

Presumptive BART for this cyclone-fired EGU burning lignite is 0.10 lb/mmBtu. NDDAQ is proposing that BART is an emission limit of 0.36 lb/mmBtu on a 30-day rolling average basis. Because NDDAQ has proposed no absolute limits on emissions, the proposed BART limits would result in a 42% reduction on a ton-per-year basis.

NDDAQ proposes that NO_X emissions be limited to 2,070.2 lb/hr on a 24-hour rolling average basis during startup. According to NDDAQ, the State of Montana in the permit for the Highwood Generating Station, EPA Region 9 in the permit for the Desert Rock Energy Center and the State of Nebraska in the Ag Soy Processing plant permit also included alternative limits for NO_x during startup and shutdown. The normal BART limit of 0.36 lb/10mmBtu will apply during all other periods including malfunctions. This is more than double the 1,152 lb/hr that would be allowed under normal operation.

However, the final (remanded) version of the Desert Rock permit states:

> Emissions from the PC boilers during startup and shutdown events shall not be subject to the emission limits in this permit which are specified in units of lb/MMBtu but shall be subject to all other limits and shall be included in the calculations of emission rates for demonstrating compliance with those limits.

We note that the approach taken by EPA regarding Desert Rock is similar to that taken by other states and limits the mass emission rate (e.g., lb/hr) to the rate under normal operation. We recommend that NDDAQ adopt this approach.

Based upon NDDAQ's analysis, addition of the proposed ASOFA+SNCR yields a cost-effectiveness of $25.6 million per dv at Theodore Roosevelt NP and $13.2 million per dv cumulatively when Lostwood WA is included.

NDDAQ Cost-Effectiveness Estimates for ASOFA+SNCR	MRYS #1
Annual Cost ($million)	$ 8.11
Visibility Improvement at TRNP (dv)	0.12
Cost-Effectiveness ($million/dv)	$ 25.61
Cumulative Visibility Improvement (dv)	0.24
Cost-Effectiveness ($million/dv)	$ 13.17

NDDAQ rejected tail-end SCR with reheat on the basis of excessive cost. NDDAQ's analysis of addition of SCR with reheat yields a cost-effectiveness of $15.4 – $22.2 million per dv at Theodore Roosevelt NP and $9.8 – $14.4 million per dv cumulatively when Lostwood WA is included.

Cost-Effectiveness for SCR with Reheat on MRYS Unit #1	NDDAQ		NPS
	low	high	
Annual Cost ($million)	$ 25.60	$ 36.90	$ 9.74
Visibility Improvement at TRNP (dv)	1.66	1.66	1.94
Cost-Effectiveness ($million/dv)	$ 15.42	$ 22.22	$ 5.03
Cumulative Visibility Improvement (dv)	2.61	2.61	3.04
Cost-Effectiveness ($million/dv)	$ 9.81	$ 14.14	$ 3.20

NPS' analysis of addition of ASOFA+SCR with reheat yields a cost-effectiveness of $5.0 million per dv at Theodore Roosevelt NP and $3.2 million per dv cumulatively when Lostwood WA is included. We believe that our cost estimates indicate that addition of SCR with reheat is reasonable based upon BART determinations and proposals we have seen nationwide to date.

Conclusions & Recommendations for MRYS #1

- NDDAQ proposed adding a new wet scrubber that achieves 95% reduction on a 30-day rolling average basis.
- We have estimated that the proposed new wet scrubber will result in an approximately 1.8 dv improvement in visibility at Theodore Roosevelt NP and 3.2 dv cumulatively when Lostwood WA is included. We commend NDDAQ for the proposed new wet scrubbers, but recommend that the limits require **both** 95% control **and** 0.15 lb/mmBtu, as well as specific caps on emissions.
- Presumptive NO_x BART for MRYS #1 is 0.10 lb/mmBtu. NDDAQ is proposing that BART is an emission limit of 0.36 lb/10^6 Btu on a 30-day rolling average basis to be met by addition of ASOFA+SNCR; this would improve visibility by 1.1 dv at Theodore Roosevelt NP and 1.7 dv cumulatively when Lostwood WA is included.

- NDDAQ proposes that NO_X emissions be limited to 2,070.2 lb/hr on a 24-hour rolling average basis during startup. We recommend that NDDAQ limit the mass emission rate (e.g., lb/hr) to the rate under normal operation.
- NDDAQ underestimated the effectiveness of adding ASOFA+SCR to MRYS #1. We suggest that ASOFSA+SCR can achieve 0.05 lb/mmBtu.
- NDDAQ overestimated the costs associated with adding SCR. In the absence of supporting documentation by NDDAQ, we also estimated a total annual cost for ASOFA+SCR with reheat at $9.7 million and $1,028 per ton.
- NPS' analysis of addition of ASOFA+SCR with reheat yields a cost-effectiveness of $5.0 million per dv at Theodore Roosevelt NP and $3.2 million per dv cumulatively when Lostwood WA is included.
- We believe that ASOFA+SCR with reheat represents BART for MRYS #1.

Milton R. Young Station Unit #2

MRYS Unit #2 is a lignite-fired cyclone boiler rated at 477 MW (gross) output; current emission control equipment consists of an ESP and a wet Flue Gas Desulfurization (FGD) system which treats 78% of the flue gas, while the remainder bypasses the scrubber and is used to reheat the stack gases. Overall sulfur dioxide (SO_2) control for Unit #2 is estimated to be about 75%. Out of 3,558 units in EPA's Clean Air Markets (CAM) database in 2008, MRYS #2 ranked #257 for SO_2 at 9,302 tons and #43 for NO_x at 8,599 tons. According to modeling results provided by Minnkota, emissions from MRYS #2 cause 2.8 dv of impairment in visibility at Theodore Roosevelt NP and 5.2 dv cumulatively when Lostwood WA is included.

A. Sulfur Dioxide

Step 1: Identify All Available Technologies
We agree that NDDAQ has chosen a reasonable suite of options.

Step 2: Eliminate Technically Infeasible Options
We agree with NDDAQ's selection of technically feasible options.

Step 3: Evaluate Control Effectiveness of Each Remaining Control Technology
We agree with NDDAQ's estimates of control effectiveness on current lignite. However, we believe that higher control efficiency is warranted for the future lower quality (3.48 lb/mmBtu) lignite.

Step 4: Evaluate Impacts and Document Results
The proposed costs ($52/kW) for upgrading the scrubber appears reasonable. NDDAQ data estimate that the scrubber upgrade would cost $565/ton.

NDDAQ Estimates for MRYS FGD Upgrade on #2 Cost Summary

Total Capital Cost:	$ 24,989,000
Total Capital Cost $/kW):	$ 52
O&M Cost:	$ 4,993,000
Total Annual Cost:	$ 8,414,000
Cost per Ton	$ 565

Step 5: Evaluate Visibility Results

Based upon data supplied by Minnkota and by NDDAQ, we have estimated that the proposed scrubber upgrade will result in an approximately 1.2 dv improvement in visibility at Theodore Roosevelt NP and 2.2 dv cumulatively when Lostwood WA is included. The NDDAQ visibility modeling yields a control-effectiveness factor for the new wet scrubber of 0.00008 dv/ton at Theodore Roosevelt NP and 0.00015 dv/ton cumulatively when Lostwood WA is included.

Determine BART

NDDAQ proposes that BART is 95% reduction **or** 0.15 lb/10^6 Btu on a 30-day rolling average basis. However, the Consent Decree requires a minimum of 90% reduction. This requirement will also be incorporated into the BART limit.

Because NDDAQ has proposed no absolute limits on emissions, the proposed BART limits would result in a 78% reduction in current SO_2 emissions on a lb/mmBtu basis and a 67% reduction on a ton-per-year basis. If coal quality deteriorates to the anticipated worst-case (3.48 lb/mmBtu uncontrolled), the proposed BART limits would default to a 96% reduction in future SO_2 emissions.

Based upon NDDAQ's analysis, addition of the new wet scrubber yields a cost-effectiveness of $7.1 million at Theodore Roosevelt NP and $3.8 million per dv cumulatively when Lostwood WA is included.

NDDAQ Cost-Effectiveness for SO_2 from	MRYS #2
Annual Cost ($million)	$ 8.41
Visibility Improvement at TRNP (dv)	1.19
Cost-Effectiveness ($million/dv)	$ 7.10
Cumulative Visibility Improvement (dv)	2.20
Cost-Effectiveness ($million/dv)	$ 3.82

We recommend 0.15 lb/mmBtu **and** 95% reduction on a 30-day rolling average basis because NDDAQ has determined that both of these levels are reasonable. Even if coal quality deteriorates to the anticipated worst-case, 96% control would still meet the 0.15 lb/mmBtu limit. We also recommend short and long-term absolute (e.g., lb/hr, tpy) caps on emissions to insure that emissions will not increase greatly over time.

B. Nitrogen Oxides

Step 1: Identify All Available Technologies

We agree that NDDAQ has chosen a reasonable suite of options.

Step 2: Eliminate Technically Infeasible Options

We agree with NDDAQ's selection of technically feasible options.

Step 3: Evaluate Control Effectiveness of Each Remaining Control Technology

We agree with NDDAQ's estimates of control effectiveness, but suggest that, if ASOFSA can reduce emissions to 0.489 lb/mmBtu as estimated by NDDAQ, then addition of SCR at 90% could bring emissions down to 0.05 lb/mmBtu.

Step 4: Evaluate Impacts and Document Results

NDDAQ has estimated a total annual cost for ASOFA with SNCR at $11.4 million with cost-effectiveness of $1,268 per ton, which it deemed to be reasonable.

For its MRYS #2 SCR with reheat cost estimates, NDDAQ simply scaled the costs estimated for the ASOFA+tail-end SCR with reheat option at LOS #2 based on the electrical output. (Please see our discussion of the LOS #2 NO_x control cost estimates.) As a result, the $377 - $388/kW capital cost estimates actually used by NDDAQ are much higher than suggested by available information (Please see Appendix B cost summaries.). NDDAQ has provided no justification for these extraordinarily high costs. Furthermore, NDDAQ did not provide any basis for their operating cost estimates which are roughly double those we estimated by applying the methods recommended by EPA in its Control Cost Manual. (Please see Appendix B.) NDDAQ has estimated a total annual cost for low-dust SCR with reheat at $47.5 – 68.5 million. The result of NDDAQ's assumptions is that SCR would cost $3,400 – 4,900 per ton, which it deemed to be reasonable.

SCR on MRYS #2 Cost Summary	NDDAQ		NPS
	low	high	
Total Capital Cost:	$ -	$ -	$ 28,345,453
Total Capital Cost $/kW):	$ -	$ -	$ 59
Catalyst ($/m^3)	$ 7,500	$ 7,500	$ 3,000
Catalyst Life (hours)	$ 8,000	$ 4,000	$ 24,000
Electricity ($/MWh)	$ 50	$ 50	$ 38
Ammonia ($/ton)	$ 750	$ 750	$ 304
Natural Gas ($/mcf)	$ 8	$ 12	$ 8
O&M Cost:	$ -	$ -	$ 10,434,981
Total Annual Cost:	$ 47,516,000	$ 68,482,000	$ 15,599,591
Cost per Ton	$ 3,405	$ 4,907	$ 898

In the absence of supporting documentation by Minnkota or NDDAQ, as recommended by the BART Guidelines, we applied the methods described in EPA's OAQPS Control Cost Manual to the ASOFA+tail-end SCR with reheat option and estimated a capital cost range of $59 /kW which is much more consistent with available literature which suggests

SCR costs ranging from \$50 - \$267/kW. We also estimated total annual costs for ASOFA+tail-end SCR with reheat at \$15.6 million and \$898 per ton. (Please see Appendix B.)

Step 5: Evaluate Visibility Results
Based upon data supplied by Minnkota and by NDDAQ, we have estimated that the proposed ASOFA + SNCR will result in an approximately 0.7 dv improvement in visibility at Theodore Roosevelt NP and 1.4 dv cumulatively when Lostwood WA is included. Our review of NDDAQ visibility modeling yields a NO_x control-effectiveness factor for the proposed combustion controls of 0.00008 dv/ton at Theodore Roosevelt NP and 0.00015 dv/ton cumulatively when Lostwood WA is included.

Based upon data supplied by Minnkota and by NDDAQ, we have estimated that addition of ASOFA+tail-end SCR with reheat will result in an approximately 1.1 dv improvement in visibility at Theodore Roosevelt NP and 2.0 dv cumulatively when Lostwood WA is included. Our review of NDDAQ visibility modeling for MRYS #1 yields a NO_x control-effectiveness factor for the ASOFA+tail-end SCR with reheat option of 0.00010 dv/ton at Theodore Roosevelt NP and 0.00019 dv/ton cumulatively when Lostwood WA is included.

Determine BART
Presumptive BART for this large cyclone furnace is based upon application of SCR to achieve 0.10 lb/mmBtu on a 30-day rolling average basis. According to the BART Guidelines, "The use of SCRs at cyclone units burning bituminous coal, sub-bituminous coal, and ***lignite*** [emphasis added] should enable these units to cost-effectively meet NO_x rates of 0.10 lb/mmBtu."

Instead of meeting the presumptive BART limit of 0.10 lb/mmBtu, NDDAQ is proposing application of SNCR and Advanced SOFA to limit NO_x emissions to 0.35 lb/mmBtu on a 30-day rolling average basis. This equates to a cost-effectiveness of \$16.1 million per dv at Theodore Roosevelt NP and \$8.4 million per dv cumulatively when Lostwood WA is included.

NDDAQ Cost-Effectiveness for SOFA+SNCR	MRYS #2
Annual Cost (\$million)	\$ 11.41
Visibility Improvement at TRNP (dv)	0.70
Cost-Effectiveness (\$million/dv)	\$ 16.18
Cumulative Visibility Improvement (dv)	1.37
Cost-Effectiveness (\$million/dv)	\$ 8.35

Because NDDAQ has proposed no absolute limits on emissions, the proposed BART limits would result in a 57% reduction in current NO_x emissions on a lb/mmBtu basis and a 34% reduction on a ton-per-year basis.

NDDAQ proposes that NO_X emissions be limited to 3995.6 lb/hr on a 24-hour rolling average basis during startup, for the reasons discussed with respect to MRYS #1. This is almost double the 2,205 lb/hr that would be allowed under normal operation. We again note that the approach taken by EPA regarding Desert Rock is similar to that taken by other states and limits the mass emission rate (e.g., lb/hr) to the rate under normal operation. We recommend that NDDAQ adopt this approach.

NDDAQ rejected ASOFA+tail-end SCR with reheat on the basis of excessive cost. NDDAQ's analysis of addition of SCR with reheat yields a cost-effectiveness of \$43.4 – \$62.6 million per dv at Theodore Roosevelt NP and \$22.4 – \$32.3 million per dv cumulatively when Lostwood WA is included.

Cost-Effectiveness for SCR w Reheat on MRYS #2	**NDDAQ**		**NPS**
	low	**high**	**low**
Annual Cost ($million)	$ 47.52	$ 68.48	$ 15.60
Visibility Improvement at TRNP (dv)	1.09	1.09	1.36
Cost-Effectiveness ($million/dv)	$ 43.45	$ 62.63	$ 11.46
Cumulative Visibility Improvement (dv)	2.12	2.12	2.64
Cost-Effectiveness ($million/dv)	$ 22.42	$ 32.32	$ 5.91

NPS' analysis of addition of basic ASOFA+SCR with reheat and using NDDAQ modeling results yields a cost-effectiveness of \$11.5 million per dv at Theodore Roosevelt NP and \$5.9 million per dv cumulatively when Lostwood WA is included. We believe that our cost estimates indicate that addition of SCR with reheat is reasonable based upon BART determinations and proposals we have seen nationwide to date.

Conclusions & Recommendations for MRYS #2

- NDDAQ is proposing upgrading the existing wet scrubber to limit SO_2 emissions to 0.15 lb/mmBtu **or** 95% reduction on a 30-day rolling average basis. We have estimated that the proposed scrubber upgrade will result in an approximately 1.2 dv improvement in visibility at Theodore Roosevelt NP and 2.2 dv cumulatively when Lostwood WA is included. We commend NDDAQ for the proposed new wet scrubbers, but recommend that the limits require **both** 95% control **and** 0.15 lb/mmBtu, as well as specific caps on emissions.
- Presumptive NO_x BART for MRYS #2 is 0.10 lb/mmBtu. NDDAQ is proposing that BART is an emission limit of 0.35 lb/mmBtu on a 30-day rolling average basis to be met by addition of ASOFA+SNCR; this would improve visibility by 0.7 dv at Theodore Roosevelt NP and 1.4 dv cumulatively when Lostwood WA is included.
- NDDAQ proposes that NO_X emissions be limited to 3,995.6 lb/hr on a 24-hour rolling average basis during startup. We recommend that NDDAQ limit the mass emission rate (e.g., lb/hr) to the rate under normal operation.
- NDDAQ underestimated the effectiveness of adding ASOFA+SCR to MRYS #2. We suggest that ASOFSA+SCR can achieve 0.05 lb/mmBtu.
- NDDAQ overestimated the costs associated with adding SCR. In the absence of supporting documentation by NDDAQ, we estimated total annual costs for ASOFA+tail-end SCR with reheat at \$15.6 million and \$898 per ton.

- NPS' analysis of addition of basic ASOFA+SCR with reheat and using NDDAQ modeling results yields a cost-effectiveness of $11.5 million per dv at Theodore Roosevelt NP and $5.9 million per dv cumulatively when Lostwood WA is included.
- We believe that ASOFA+SCR with reheat represents BART for MRYS #2.

Section Eight: Visibility Modeling

As noted in Section 8.1, NDDAQ used a unique hybrid modeling approach to air quality modeling to project the 2018 reasonable progress goals. This approach involved nesting the local CALPUFF domain within the WRAP CMAQ domain, and applying the Lagrangian CALPUFF model in a retrospective sense to more realistically define plume geometry for local point sources.

We appreciate the effort by NDDAQ to address some of the limitations of the larger (36 km) grid and limited near-field impacts of the WRAP regional modeling. However, we are concerned that the modeling system developed by NDDAQ has shortcomings that limit its usefulness as an alternative modeling approach.

NDDAQ indicates that the purpose of the hybrid modeling is as weight of evidence to discount the impact of international (particularly Canadian) emissions and to better represent plume dispersion from point sources, particularly those closer to the Class I areas. While the CMAQ 36 km grid resolution does allow dilution of the plumes from point sources, ND's hybrid modeling assumptions raise more questions that are answered. CALPUFF does allow tracking of individual plumes but the model chemistry is much simplified compared to CMAQ and the methods required to normalize CMAQ results to CMAQ-CALPUFF hybrid results becomes quite elaborate and questionable.

We raise the following technical issues with the CALPUFF application:

- Ammonia is known to be an important input to determine the amount of ammonium nitrate (NH_4NO_3) formed in CALPUFF. Regional ambient concentrations of ammonia are poorly understood. ND has one ammonia monitor at Beuluh; please describe the type of monitor and the land use at Beuluh compared to other areas of the CALPUFF domain. We question if this monitor is representative of the CALPUFF domain. We note that monthly average NH3 from 2001-2002 was used as background ammonia in CALPUFF after removing days influenced by a source region. The draft Plan should identify that source region.

- EPA disapproved the use of the Ammonia Limiting Method to define NH3 levels in the VISTAS application cited by NDDAQ.

- For POSTUTIL, hourly ammonia data for 2001 -2003 were used and the Plan does not mention removing data. The Plan should identify if different years were used for the two applications. It appears that the ammonia levels at Lostwood were doubled compared to measured values based on the expectation that Lostwood is closer to ammonia sources in Canada. However, that adds a subjective adjustment to the CALPUFF modeling that brings into question the presumption that CALPUFF modeling is more accurate than just using CMAQ at 36 km.

- We note that four ozone monitors in central ND were selected to represent background ozone in CALPUFF. Are there only four ozone monitors in the CALPUFF domain? Table 8.6 says background value for ozone was 30 ppb, but does not link this to monitoring data.

We question the Hybrid model performance evaluation. Model performance evaluations are usually based on raw model output. We understand that the Hybrid model results were normalized before evaluation and then were normalized again to the WRAP baseline results. The need to normalize the CALPUFF relative response factors to the WRAP results, brings into question the value of using the CALPUFF hybrid regional model to discern the benefits of NDDAQ strategies.

In summation, we are not certain that the results from the Hybrid modeling have a substantial impact on the overall result. The conclusions under either the WRAP modeling or the Hybrid model are the same; the two Class I areas in North Dakota do not meet the uniform rate of progress guidance for this first planning period.

Section 8.6, including Figure 8.10, describes a possible way to account for international emissions when assessing the progress toward the goal of natural conditions. While we agree that examining the contribution to extinction for each aerosol species is a good approach to understanding if a State is meeting its fair share of emissions reductions associated with visibility impacts at a Class I area, the method described in this section and in the figure raise concerns since there was no assessment of the international component of the natural condition estimate. The value in 2064 illustrated in Figure 8.10 uses the same natural condition endpoint for the total extinction as well as the "U.S. Source" extinction, yet the 2064 natural condition estimates for aerosol species include some global or international component. We believe that a better way to address reasonable progress by extinction component is to assess the reduction needed for each aerosol species measured in the baseline period to the end of the first planning period and then assess if a state's plan achieves a comparable reduction for its share of extinction at the Class I areas.

Section Nine: Reasonable Progress Goals

The State should rely on WRAP regional modeling as the primary tool for demonstrating progress toward visibility improvement goals. The CMAQ-CALPUFF hybrid modeling is problematic in several ways and gains ND little benefits compared to using WRAP products. Two WRAP products that were omitted but should be included to help ND in making its reasonable progress determination are 1) Weighted Emissions Potential (WEP) and 2) extinction glide paths for SO_4, NO_3, and OC.

The uniform rate of progress glide path cannot be revised to account for contributions from natural sources or international sources under current or 2018 conditions without also removing these contributions from the 2064 endpoint. While the contribution from natural and international sources by 2064 is unknown, it may be comparable to current contributions. Therefore removing the estimated contributions from current conditions without also accounting for those contributions to the 2064 endpoint inappropriately changes the slope of the uniform rate of progress

It would be more appropriate to use the WRAP CAMx-PSAT results to demonstrate the relative contributions to sulfate and nitrate from Canadian and ND emissions at the North Dakota Class I areas. The Plan has already included these results in Table 6.7.

We suggest NDDAQ use the WRAP extinction glide paths to show the improvement in SO_4 or NO_3 due to emissions reductions from all sources in the WRAP 2018 inventory, and compare the ND emissions reductions by 2018 to emissions reductions from Canada and neighboring states. It would be informative for the Plan to include what percent of the State's total SO_2 and NO_X emissions from point sources is being reduced under BART. What other point source or area source reductions are reasonable?

For stationary sources, NDDAQ developed a methodology to look at options for controls for sources, beyond the source subject to BART, contributing to the major components of aerosol extinction on the worst 20 percent days. While we generally agree with the use of emissions over distance (Q/d) as a screening tool, we note that the Heskett facility was not included in Table 9.4 even though NDDAQ proposes to exclude the source from BART requirements.

Based on Q/d and some source process information, NDDAQ narrowed the focus of any additional control measures under the reasonable progress measures to the Basin Electric Antelope Valley Station (AVS) facility, the Otter Tail Power Coyote Station, the Dakota Gasification Great Plains Synfuels Plant, and the Hess Corporation Tioga Gas Plant.

Table 9.9 summarizes the results of assessing the costs and visibility improvement associated with possible controls on these facilities. The two power generation facilities, Coyote and AVS, have emissions and Q/d impacts that are similar, if not greater than, BART sources that will be required to add controls. The methodology to calculate visibility improvements noted in Table 9.9 are not explained in this section but appear to be some calculation of changes in the long-term metric of the 20 percent worst visibility days. These sources likely contribute to higher impacts on a daily basis, and a reduction in their emissions would be part of a broad strategy to reach natural conditions at the Class I areas. As such NDDAQ should examine the total improvement from the suite of sources as part of its reasonable progress assessment, not a simple unit by unit approach.

The assessment of non-air quality impacts on page 181 in the draft SIP does not address the substantial human health benefits associated with reductions in fine particulate concentrations resulting from additional control of SO_2 and NO_X emissions from Coyote and AVS since they would become the newest and highest emitters of these pollutants after implementation the SIP as drafted.

The decision on additional point source controls would be better informed by analysis of the how the emissions from sources within the State contribute to nitrate and sulfate concentrations in Class I areas, both inside and outside of the State, in the baseline period compared with the model projections in 2018. If BART controls on stationary sources as well as expected reductions from Federal mobile source, small engine, and fuel requirements would achieve a reduction that, had all other contributing States and other regions met similarly, would put the total aerosol extinction on the uniform rate of progress path, then the State could better support a limited approach to additional controls in this first planning period. However, based on our review of the information supplied in the draft Plan and its appendices, we believe there are cost-effective controls for the Coyote and AVS facilities that should be implemented under the reasonable progress provisions.

Section Ten: Long-Term Strategy

We appreciate that a description of the State's smoke management activities regarding anthropogenic fire is referenced in the Plan. We agree that current rules are sufficient to address the small extinction associated with this component. We also appreciate the Plan referencing conservation tillage as an approach to reduce windblown dust.

On Page 184, there is discussion of the reduction in sulfur dioxide emissions from the R.M. Heskett Station No. 2. As noted earlier, we believe this facility is subject to BART and should be assessed under the BART provisions. In addition, the reduction in emissions reflect a 21 percent reduction from current emissions. The 70 percent coal-to-stack removal cited in the draft Plan implies a greater reduction from current emissions.

We request that NDDAQ include in the Long-Term Strategy a linkage between the prevention of significant deterioration program and its assessment of visibility impacts and the Regional Haze Plan in the SIP. This will ensure that new sources are reviewed in a manner that does not jeopardize the reasonable progress goals established by this Plan.

Section Eleven: FLM Consultation and Coordination

We appreciate the ongoing efforts of NDDAQ to consult with the federal land management community.

Section Twelve: Public Participation and Review Process

No comment.

TAKE PRIDE IN AMERICA

IN REPLY REFER TO:

October 23, 2009

N3615 (2350)

Mr. Terry L. O'Clair, P.E.
Director, Division of Air Quality
North Dakota Department of Health
918 E. Divide Avenue
Bismarck, North Dakota 58501-1947

Dear Mr. O'Clair:

On August 26, 2009, we received North Dakota's draft implementation plan to address regional haze for review. We appreciate the opportunity to work closely with the State through the initial evaluation, development, and, now, subsequent review of this plan. Cooperative efforts such as these ensure that, together, we will continue to make progress toward the Clean Air Act's goal of natural visibility conditions at all of our most pristine National Parks and wilderness areas for future generations.

This letter acknowledges that the U.S. Department of the Interior, U.S. Fish and Wildlife Service (FWS), and National Park Service (NPS) have received and conducted a substantive review of your revised proposed Regional Haze Rule implementation plan in fulfillment of your requirements under the federal regulations 40 CFR 51.308(i)(2). Please note, however, that only the U.S. Environmental Protection Agency (EPA) can make a final determination regarding the document's completeness and, therefore, ability to receive federal approval from EPA.

As outlined in a letter to each State dated August 1, 2006, our review focused on eight basic content areas. The content areas reflect priorities for the Federal Land Manager agencies, and we have enclosed comments associated with these priorities. Our major concerns with the draft plan include: 1) the separation of Theodore Roosevelt National Park units into separate Class I areas for assessing air quality impacts, 2) the exemption of the Unit #2 at the R.M. Heskett Station from Best Available Retrofit Technology (BART) review, 3) concerns over BART determinations (i.e., our review concludes that additional sulfur dioxide and nitrogen oxide emission reductions are achievable through the BART process), and 4) the methods used for determining reasonable progress at Class I areas affected by emissions from North Dakota sources. For further information regarding our comments, please contact Bruce Polkowsky of the NPS Air Resources Division at 303-987-6944, or Tim Allen of the FWS Branch of Air Quality at 303-914-3802.

Again, we appreciate the opportunity to work closely with the State of North Dakota and compliment you on your hard work and dedication to significant improvement in our nation's air quality values and visibility.

Sincerely,

Christine

Christine L. Shaver
Chief, Air Resources Division
National Park Service

Response to Forest Service
Comments October 14, 2009

General Comments

Comment 1: We agree with previous comments by the National Park Service (NPS) that Theodore Roosevelt National Park should be treated as one Class I area, not three.

Response: North Dakota has two Class I areas within its boundaries: the Theodore Roosevelt National Park which consists of three separate and distinct units and the Lostwood National Wildlife Refuge Wilderness Area. The North Dakota Department of Health (Department) considers the three units of Theodore Roosevelt National Park to be three separate areas for modeling purposes for the following reasons:

A. Theodore Roosevelt National Park (TRNP) as a PSD Class I area consists of three units (see 44 FR (November 30, 1979) at 69125 and 69127, 40 CFR § 81.423 and NDAC § 33-15-15-01.2 (Scope) relating to 40 CFR 52.21(e)). The areas are not contiguous. The North Unit and South Unit are separated by approximately 38 miles.

B. Federal regulation, 40 CFR 51.301, states "*Adverse impact on visibility* **means, for purposes of section 307, visibility impairment which interferes with the management, protection, preservation, or enjoyment of the visitor's visual experience of the Federal Class I area. This determination must be made on a case-by-case basis taking into account the geographic extent,** intensity, duration, frequency and time of visibility impairments and how these factors correlate with (1) times of visitor use of the Federal Class I areas, and (2) the frequency and timing of natural conditions that reduce visibility. This term does not include effects on integral vistas." (Emphasis added) Combining the three units of TRNP into a single area for visibility analysis fails to address the "geographic extent" of any visibility impairment.

C. The North Unit is not visible from the South Unit and vice versa. The commingling of receptors from the units for a visibility analysis misrepresents the ability of a park visitor to observe features in another unit.

Any viewable scenes outside any unit of TRNP from within the unit are "integral vistas". The effects on integral vistas are not considered when determining whether an adverse impact on visibility will occur. There are no geological features, terrain or structures in any unit of TRNP that are viewable from another unit across the land regions separating the units. For example, terrain peaks in the South Unit would have to rise at least 900 feet above terrain in the North Unit, due to the Earth's curvature, to be seen by a visitor in the North Unit. So the visual range of visitors in one unit does not include aspects of another unit.

D. The Department has treated the units as separate Class I areas for 30+ years for purposes of PSD increment consumption without objection from EPA or the FLMs prior to 2006.

E. Treating the three units as a single Class I area effectively extends Class I status to areas between the units which are classified as Class II by rule and law.

F. The units have three different names, the South Unit, the North Unit and the Elkhorn Range Unit.

Comment 2: In a number of places in the RH SIP, ND characterizes its impact on its own class CIAs as "small." We note that this is a subjective term. Based on our review of RH SIPs from other states, we do not consider ND's percent contribution to visibility impairment in its own CIAs as being significantly different (i.e. smaller) than the other CIA owner states. For example ND's contribution to its CIAs is very similar to Minnesota's contribution to its CIAs. If ND feels this is not true, ND should include data to support this position. Nevertheless each State must demonstrate that it is obtaining "*its share of the emission reductions needed to meet the progress goal for the area*," per 40 CFR 51.308 (d) 3.

Response: We agree that "small" is a subjective term. However, Canada and sources outside the WRAP's modeling domain are larger contributors to visibility impairment in North Dakota's Class I areas. North Dakota sources contribute 21% or less of the visibility degradation to TRNP and LWA. We believe the word "small" is an appropriate descriptor.

Comment 3: The RH SIP should explain how the reasonable progress goals (RPGs) will be revised once the RH SIPs from the neighboring contributing states are available.

Response: The following paragraph has been added to Section 11.3.
In addition, North Dakota commits to revise the implementation plan, including the reasonable progress goals, once RH SIPs from neighboring states become available and are approved by EPA, or if the unexpected or unforeseen occurs. This would include, but not limited to, projected future emissions reductions that do not occur, are distributed differently over an alternate geographic area, or are found to be incorrect or flawed. These revisions will be made within one year as required by §51.308(d)(4). North Dakota also commits to accelerate this revision schedule if the present RH SIP is found to be significantly flawed and the 2018 reasonable progress goals cannot be reasonably attained.

Comment 4: We note that the State of Minnesota specifically asked ND to analyze the feasibility of reducing electrical generating unit (EGU) emissions in the state to less than 0.25 pounds per million Btu (lb/MMBtu) for sulfur dioxide (SO_2) and less than 0.22 lb/MMBtu for nitrogen oxides (NOx). We found a response from ND that outlined their disagreement with the premise of Minnesota's "ask." Additional information would be helpful comparing the emission level of ND's EGUs after the installation of controls prescribed under the Best Available Retrofit Technology (BART) and Reasonable Progress (RP) analyses.

Response: We believe the lb/10^6 Btu metric proposed by Minnesota is inappropriate since it is not based on the four factors that must be considered as required by rule and law. We believe cost must be considered, especially on a dollar per deciview basis.

Comment 5: We ask US EPA Regions 5 and 8 to arbitrate the disagreement between ND and Minnesota regarding Minnesota's "ask," as well as working with Canada on reducing emissions from sources in that country, especially the power plants mentioned by ND on page 53 of the RH SIP. This is especially relevant since power is sent across the US-Canada border.

Response: None required

General BART

Comment 6: We feel the decision to make Heskett Unit 2 not subject to BART is based on inappropriate modeling. Technical reasons were discussed on the call between ND and the Federal Land Managers (FLMs) on September 22, 2009, including the use of using fine grid (1 km) modeling. Department of Interior modeling staff will provide more details. Please complete a full BART analysis for this unit. Alternatively, if Heskett is not found to be subject to BART it should be included in the State's reasonable progress analysis and a complete suite of possible control options examined in detail.

Response: Heskett Unit 2 is being reevaluated. This source will be addressed in a future supplement to this SIP revision.

Comment 7: We would also like to note that the statement that Heskett is proposing a 70% SO_2 emission reduction is misleading. Baseline SO_2 emissions were reported as 2400 tons and the reduction project was reported to reduce emissions by 740 tons. This results in a 31% reduction.

Response: So noted

Comment 8: EPA BART guidelines (Federal Register, July 6, 2005) on page 39170 directs the State to compare the 98 percentile days, pre-control versus post-control, so we disregarded the 90 percentile days presented in the RH SIP on page 67.

Response: The affected sources and the Department have provided both the 90th and 98th percentile results for the reader. The only facility in North Dakota that is subject to the BART guideline is Coal Creek Station for NO_x only. The BART Guideline states "For sources other than 750 MW power plants, states retain the discretion to adopt approaches that differ from the guideline." Therefore, the Department is allowed to consider any type of visibility improvement information in determining BART.

Comment 9: On page 68 ND states "Though single-source modeling is specified in the BART guidance for determining degree of visibility improvement, it is clear that this modeling overstates the real single-source visibility impact." Please add a reference or basis for this statement. ND also adds "an observer's perception of visibility change is affected by the total loading of visibility-affecting species in the atmosphere." We agree. On clean days visibility can be impaired by a small amount of air pollution. That is why it is important to use clean days as a baseline from which to measure impairment from a source. Otherwise clean days are not protected.

Response: Visibility on clean days is being protected, as demonstrated by WRAP and NDDH results for the 20% cleanest days. The modeling results for the 20% cleanest days indicate no deterioration of visibility on the 20% cleanest days at North Dakota Class I areas. But according to the Regional Haze Rule, the focus of visibility improvement demonstrations is the *20% worst visibility days*, not the cleanest days. There is no requirement to make the cleanest days cleaner, the Rule specifies only that visibility on cleanest days should not degrade. A calculated visibility change using single-source modeling is only accurate or applicable during clean visibility background conditions, when a Class I area is impacted by a single source's plume. This is certainly not the case for the 20% worst visibility days. For the 20% worst visibility days, a realistic change in visibility must be calculated with respect to current baseline conditions, which include the cumulative impact of many sources. Given that the deciview calculation is based on the observer's perception, single source modeling will overstate perceived visibility change on the 20% worst days.

The basis for the NDDH statement on single-source modeling overstating the real impact relates also to the cumulative visibility improvement analyses conducted by WRAP and NDDoH for 2018. These sophisticated analyses indicate that overall visibility improvement (20% worst days) will actually be much lower than the additive impact of single-source modeling associated with BART degree of visibility improvement. In other words, the single-source modeling results conflict with the results obtained by WRAP. You cannot claim the single-source modeling is accurate for depicting real visibility improvement without disparaging the results obtained by WRAP. The NDDoH believes the sophisticated WRAP modeling is more accurate.

Comment 10: In the BART section of the SIP ND appears to disregard the importance of EPA's presumptive BART limits. EPA considers these limits to be "generally cost effective" and in the case of scrubbers states, "We expect that scrubber technology will continue to improve and control costs continue to decline" (FR, 7/6/07, pg 39171).

Response: The Department did not disregard the presumptive BART emission rates. As pointed out earlier, only Coal Creek Station (for NO_x only) is subject to the BART guideline and presumptive BART emission rates. Coal Creek Station will meet the presumptive limits for NO_x. Although not subject to the presumptive levels, Leland Olds 1 will be below the NO_x presumptive level. All sources except Stanton 1 will be required to meet the presumptive level for SO_2 even though the presumptive levels do not apply.

SO_2 BART

Comment 11: MR Young Unit 2

A. We feel the form of the emission limit needs to be reviewed. For example, the emission limit is specified as 95% control efficiency (CE). Therefore the pounds per million Btu (lb/MMBtu) limit should be 0.1 or else the effective limit becomes 0.15 lb/MMBtu which is 90% control. MR Young Unit 1 is specified as having just a CE limit and no alternative lb/MMBtu. If Unit 1 can comply with just a CE limit we see no reason why Unit 2 can't also do the same.

B. At the end of the BART analysis, ND changes the baseline emission level from 2.0 lb/MMBtu to 3.5 lb/MMBtu, which effectively raises the final BART limit. We feel the same baseline emission level should be used throughout the whole BART analysis, which includes calculating the costs per ton, as well as setting the limits.

Response:

A. The commenter is incorrect in the assertions on the SO_2 emission rates. If average sulfur content coal is burned, 95% removal efficiency will be 0.11 lb/10^6 (annual average) and 0.17 lb/10^6 Btu based on a reasonable worst-case sulfur content of 1.46% (worst-case sample was 5.6%). To obtain a 30-day rolling average emission limit, the annual average would have to be adjusted up approximately 33%. This yields a 30-day rolling average based on 95% reduction of 0.15 lb/10^6 Btu for the average coal and 0.23 lb/10^6 Btu for a reasonable worst-case. Minnkota has agreed to limit emissions to 0.15 lb/10^6 Btu or 95% reduction. The Consent Decree for the facility requires a minimum of 90% reduction. Therefore, when Minnkota chooses to comply with the 0.15 lb/10^6 Btu, they will also have to achieve at least 90% reduction. Based on average coal sulfur 95% reduction will be required to comply with the 0.15 lb/10^6 Btu limit. Under the Consent Decree, Unit 1 does not have the option of meeting a 0.15 lb/10^6 limit.

B. The calculations in the Department's analysis have been revised based on the projected increase in sulfur content to 0.93% from the baseline of 0.86%. The annual average sulfur content was used for the analysis and the projected emission rate of 0.11 lb/10^6 Btu (annual average) was then adjusted to a 30-day rolling average of 0.15 lb/10^6 Btu. The higher "reasonable worst-case" sulfur content was not used to determine the emission limit of 0.15 lb/10^6 Btu on a 30-day rolling average basis."

Comment 12:

A. It is unclear why this unit can't install a wet scrubber and meet the same limit as the Leland Olds Unit 1 (95% CE) which is a boiler of similar size, age, firing type, and is also along the Missouri river. Please include a discussion of how the relevant BART factors are different for the two units. The costs for a wet scrubber at Stanton appear to be reasonable ($1480/ton).

Response: The Department eliminated a wet scrubber from consideration as BART at Stanton Unit 1 based upon a combination of factors. These include the relatively high incremental cost of $4,179 per ton of SO_2 removed when burning lignite and $6,302 per ton of SO_2 removed when burning PRB, the additional environmental impacts of a wet scrubber and the fact that a wet scrubber will remove a relatively small amount of SO_2 when compared to a spray dryer (with a small corresponding visibility improvement).

The additional environmental considerations are further outlined below:

- A wet scrubber is estimated by Great River Energy (GRE) to use as much as 20% more water or approximately 15 million gallons per year of additional water.

- It is assumed that a wet scrubber system will require additional on-site ponding. GRE has identified two potential areas on site that could be used for the additional ponding. The areas include the existing ash pile, which would have to be excavated and moved, or the abandoned ash disposal area adjacent to the river, which reportedly has geotechnical deficiencies.

- Dry scrubbers are purported to achieve higher mercury control efficiency on lignite and PRB as compared to a wet scrubber. In addition, future mercury control requirements could result in high concentrations of mercury in the ponds and prove problematic to discharge.

Although Leland Olds Unit 1 and Stanton Unit 1 are both located on the Missouri river, the facilities are not located at the exact same location. As indicated above, site-specific factors were considered when making the determination to eliminate a wet scrubber from consideration as BART at Stanton Unit 1. Basin Electric, operator of Leland Olds 1, also has a much larger area available for siting a dewatering pond.

B. Again, for this source, ND adjusted the baseline emission rate up for both fuels (i.e. from 1.8 to 2.4 lb/MM Btu for lignite and from 1.2 to 1.6 lb/MM Btu for sub-bituminous). As stated above we feel the baseline emission rate should be the same throughout the analysis. If the baseline emission rate were the same throughout the analysis, it would reduce the cost per ton presented, which already appears to be reasonable.

Response: The Department's economic analyses were based on uncontrolled annual SO_2 emissions of 1.81 lb/million Btu for lignite and 1.2 lb/million Btu for PRB coal. The proposed BART emission limits for SO_2 are based on a 30-day rolling average (as opposed to an annual average) with 90% reduction and also includes emissions from startups, shutdowns and malfunctions. Based upon historical SO_2 emissions data for spray dryers and fabric filters at facilities burning North Dakota lignite, we have determined that an increase of 33% is warranted to adjust from an annual average SO_2 emission rate to a 30-day rolling average emission rate. The discussion regarding potential SO_2 emissions as high as 2.4 lb/million Btu for lignite and 1.6 lb/million Btu for PRB coal was intended to show that higher sulfur coal could be encountered (see Appendix E, Sulfur Content Statistical Analysis, of the GRE BART Analysis). The Forest Service states that the cost per ton for SO_2 removal already appears to be reasonable. The Department agrees that the wet scrubber cost effectiveness of $1,480/ton of SO_2 removed when burning lignite and $2,232/ton of SO_2 removed when burning PRB are reasonable. However, the Forest Service chooses to ignore the relatively high incremental cost of $4,179 per ton of SO_2 removed when burning lignite and $6,302 per ton of SO_2 removed when burning PRB. As indicated in the response to comment #12.a. above, the Department appropriately considered the five factors when making the decision to remove a wet scrubber from consideration as BART at Stanton Unit 1.

NO_x BART

Comment 13: We would like to comment on an ancillary issue. ND states in the individual BART determinations, "The Department believes pilot scale testing would prove to be very beneficial in addressing the items of concern and provide a more detailed professionally reliable cost estimate. However, the BART process cannot mandate pilot testing be conducted to determine costs." We agree and suggest that should a decision be made not to apply SCR with this SIP, additional pilot testing would be useful and encourage ND to include enforceable schedules in the long term strategy portion of its RH SIP. Minnesota took just such an approach in its RH SIP for the taconite industry which, like lignite fired power plants in North Dakota, had little data on NOx controls and is almost entirely in one state.

Response: Although we believe it would be beneficial to have pilot test data, the Department must make its decision regarding BART based on available data. The U.S. EPA, Region 8 has indicated that such "commitments" within the regional haze SIP are unacceptable and would not be considered in determining whether to approve the SIP.

The Department has been working with industry to get pilot testing completed. By the next planning period, we expect to have much more data.

Comment 14: We note that Leland Olds Unit 2 and MR Young Units 1 and 2 do not meet presumptive BART, which as noted above is described by EPA as "generally cost effective."

Response: These sources are not subject to the BART guidelines or the presumptive BART emission limits. EPA did not address the flue gas characteristics of North Dakota lignite when determining the presumptive levels. The BART guideline states "As with other presumptive limits established in this guideline, you may determine that an alternative level of control is appropriate based on your consideration of the relevant statutory factors." The Department has based its BART decision on the relevant factors and selected a level of control different from the presumptive level. Our explanation for our selection is found in the SIP, Appendix B.

Comment 15: The startup/shutdown BART exemptions proposed for MR Young Units 1 and 2 are not necessary since the limit will be in the format of a 30 day rolling average. We have not seen such exemptions in BART determinations in other states. Four other BART units in ND are also using SNCR and are not asking for similar treatment. If these exemptions are allowed they should be severely limited by enforceable permit conditions, otherwise the integrity of the BART limit will be compromised.

Response: The BART exemption for startup is necessary since Minnkota did not build excess emissions during startup into the proposed BART limit (see discussion in Minnkota's October 2006 analysis – Appendix C). Minnkota prepared a BART analysis which is consistent with the BACT analysis required by their Consent Decree. The Consent Decree, paragraph 66 requires Minnkota to address startup NO_x emissions separately. Therefore, the BART limit is being proposed to be consistent with the BACT limits. Other facilities have included startup/shutdowns in their proposed BART limits. Leland Olds Unit 2 has a baseline emission rate of 0.67 lb/10^6 Btu compared to Minnkota Unit 1 which has a baseline of 0.78 lb/10^6 Btu.

The proposed BART limits are identical at 0.35 lb/10^6 Btu except for a separate limit for Minnkota during startup.

Comment 16: We applaud ND for the process it took to identify sources for which additional controls could be potentially applied under reasonable progress. Based on the Q/d metric, clearly Coyote and Antelope Valley Station (AVS) have visibility impacts that are on par with, or exceed many of the subject to BART sources. These subject to BART sources were all prescribed to install additional SO_2 and NO_x controls by ND in the draft SIP.

a. SO_2 - Improvements to the existing spray dryer system should be included as an option, and costs determined, in the control technology analyses done for the AVS units. EPA states the following for existing flue gas desulfurization systems in their BART guidelines, "There are numerous scrubber enhancements available to upgrade the average removal efficiencies of all types of existing scrubber systems…" This is the approach taken by ND for the Coal Creek units and MR Young Unit 2.

b. NO_x - When comparing the emission rates from AVS and Coyote to the rest of the State's EGUs, AVS and Coyote would be the newest and the dirtiest. We note that ND states that moderate control options such as LNB/SNCR at 65% CE for AVS and ASOFA/SNCR at 55% CE at Coyote are reasonable (page 180 of the RH SIP).

ND claims that the improvement in visibility from installing controls at AVS and Coyote is too small to require their installation. It is unclear which modeling method/protocol was used to produce the visibility results in Table 9.9, which makes their use problematic. Nevertheless AVS and Coyote are of the same general size, and located in the same general area, as the BART sources. Therefore we feel reductions at AVS and Coyote are equally important to those at the BART sources. ND required controls at the BART sources. The amount of reductions from AVS and Coyote are significant – in the range of 30,000 tons of combined NO_x and SO_2, not including any additional SO_2 that could be reduced from upgrading the spray dryers at AVS. Please consider controls on AVS and Coyote such as LNB/SNCR at 65% CE for AVS and ASOFA/SNCR at 55% CE at Coyote.

Response:

a. Improvements to the spray dryers at AVS I and II are underway. This has been noted in the revised SIP. The Department looked at the improvements to the scrubber system at Antelope Valley Station. This included meeting the presumptive emission rate of 0.15 lb/10^6 Btu. When this emission rate was modeled with the presumptive NO_x emission limit, it only improved visibility 0.045 deciviews at LWA and 0.031 deciviews at TRNP during the 20% worst days (total for the two units). For the Coyote Station, visibility improved only 0.04 deciviews at LWA and 0.02 deciviews at TRNP when the scrubber efficiency was 95% and NO_x emissions were reduced 55%. The Department considers this amount of improvement to be unsubstantial.

b. The Department considered the cost to be reasonable on a dollar per ton basis. However, EPA's guidance for determining reasonable progress states "Therefore, in assessing additional emissions reduction strategies for source categories or individual large scale sources, simple cost effectiveness estimates based on a dollar-per-ton calculation may not be as meaningful as a dollar-per-deciview calculation." The Department evaluated the cost on a dollar-per-deciview basis and found it to be unreasonable.

The modeling in Table 9.9 was based on a cumulative analysis of the improvement in the 20% worst days. The Department will further describe the modeling procedure in the SIP.

Comment 17: Under the section on "Energy and non-air quality environmental impacts," we encourage ND to include the environmental and health *benefits* of installing additional controls. In general, the benefits of installing controls on EGUs far outweigh the costs.

a. For example the report EC/R did for Midwest RPO (http://www.ladco.org/reports/rpo/consultation/index.php) shows that the health benefits of reducing SO_2 and NO_x emissions under a region-wide SO_2 and NO_x control strategy are generally expected to outweigh the costs of control. These health benefits stem from the reduced ambient levels of PM and ozone which would result from the control of SO_2 and NO_x. "When benefits in the entire modeling domain were considered, the estimated values of these benefits outweighed the projected costs of control by more than a factor of 10" (page 106). This does not include other environmental benefits of controls which are harder to quantify but nonetheless important (e.g. reduction in mercury deposition).

b. In the original Clean Air Interstate Rule (CAIR), the range of annual *net* benefits (benefits less costs) to society were calculated to be approximately \$71.4 to \$60.4 billion in 2010 and \$98.5 to \$83.2 billion in 2015 (FR 5/12/05, pg 25305).

Response: (a & b)

The Energy and Non-Air Quality Environmental Impacts Analysis does not address health effects from air emissions. As stated in the BART guideline "In the non-air quality related environmental impacts portion of the BART analysis, you address impacts **other than air quality** [emphasis added] due to emissions of the pollutant in question. Such environmental impacts include solid or hazardous waste generation and discharges of polluted water from a control device."

Even though health effects are not evaluated under this section of the BART analysis, the Department reviewed ambient monitoring day in the vicinity of Antelope Valley Station and Coyote Station. Five ambient monitors are operated in the immediate area. In 2008, the maximum 3-hour SO_2 concentration was 39 ppb (7.8% of the NAAQS), the maximum 24-hour SO_2 concentration was 9 ppb (6.4% of the NAAQS) and the maximum annual average was 1.8 ppb (6% of the NAAQS). For NO_2, the maximum annual average was 2.7 ppb (5.1% of the NAAQS). Given the low concentration of these pollutants, any benefits to health would be extremely hard to quantify.

Comment 18: We do not support the method used to adjust the glidepath to account for Canadian emissions used in the RH SIP. We do support DOIs suggesting of using species-specific information provided by the Western Regional Air Partnership (WRAP).

Response: Regarding the statement, "we do not support the method used to adjust the glidepath for Canadian emissions used in the RH SIP", the commenter does not state what is wrong with the method, nor is any alternative provided. Therefore, the NDDoH has no basis to respond to this comment. As indicated in the SIP, the NDDoH approach for the adjusted glidepath is intuitive and consistent with proposals from other organizations (e.g., CENRAP Policy Oversight Group – Summary of PM Source Apportionment Modeling and 2018 Projection Approaches, March 2007).

WRAP species-specific information is included in Section 8 of the SIP.

Comment 19: We found no specific discussion in the draft SIP that considered contingency measures or procedures which could be triggered if the unexpected or unforeseen occurs. For example, if projected future emissions reductions do not materialize, or are distributed differently over an alternate geographic area, emission inventories could be found to be incorrect or flawed. Are there adaptive management strategies or increased review strategies which could be implemented in those situations? What will be done in five-years if North Dakota is over their projected emissions inventory? The SIP should provide a contingency plan to address these concerns.

Response: The following paragraph has been added to Section 11.3.
In addition, North Dakota commits to revise the implementation plan, including the reasonable progress goals, once RH SIPs from neighboring states become available and are approved by EPA, or if the unexpected or unforeseen occurs. This would include, but not limited to, projected future emissions reductions that do not occur, are distributed differently over an alternate geographic area, or are found to be incorrect or flawed. These revisions will be made within one year as required by §51.308(d)(4). North Dakota also commits to accelerate this revision schedule if the present RH SIP is found to be significantly flawed and the 2018 reasonable progress goals cannot be reasonably attained.

Comment 20: We request that ND note that there is a linkage between the PSD program, its visibility impacts, and the need to protect the 20 percent best visibility days. An adequate relationship between the SIP and ND's PSD program also helps ensure that new sources do not jeopardize the reasonable progress goals established by the RH SIP.

Response: A discussion of the linkage between the PSD program and Regional Haze Program will be added in Section 10 as Paragraph 10.7.

10.7 Prevention of Significant Deterioration

In North Dakota, new and modified existing major stationary sources triggering significance thresholds are analyzed under the Prevention of Significant Deterioration (PSD) permitting program. The PSD program rules are found in NDAC Chapter 33-15-15 and have been approved as a part of the North Dakota SIP by EPA. The PSD permitting program is a integral part of North Dakota's long term strategy for meeting its regional haze goals.

Among other things, the PSD permit program is designed to protect air quality and visibility in Class I areas by requiring best available control technology (BACT) and involving the public in permit decisions. The PSD permitting process requires a technical air quality analysis and additional analyses to assess the potential impacts of emissions on soils, vegetation and visibility. The cumulative impacts of emissions subject to the PSD program will be evaluated to ensure there is no degradation from baseline conditions on the 20 percent worst days and the 20 percent best days.

Therefore, North Dakota's current PSD program ensures that visibility at the Class I areas will not be impacted by growth in stationary sources.

Response to DOI Comments
October 23, 2009

Comment 1: (Section Two: Overview)

We disagree with the statement on page 8 claiming that North Dakota has four mandatory federal Class I areas as defined under the Clean Air Act. Based on the legislation establishing Theodore Roosevelt National Park and the Clean Air Act, North Dakota has two mandatory federal Class I areas (i.e., Theodore Roosevelt NP and the Lostwood Wilderness Area). The entire acreage of Theodore Roosevelt NP is one Class I area under the Clean Air Act, and should be treated as such for all protection purposes, such as assessing for increment consumption and calculating visibility impacts.

Response: North Dakota has two Class I areas within its boundaries: the Theodore Roosevelt National Park which consists of three separate and distinct units and the Lostwood National Wildlife Refuge Wilderness Area. The Department considers the three units of Theodore Roosevelt National Park to be three separate areas for modeling purposes for the following reasons:

A. Theodore Roosevelt National Park (TRNP) as a PSD Class I area consists of three units (see 44 FR (November 30, 1979) at 69125 and 69127, 40 CFR § 81.423 and NDAC § 33-15-15-01.2 (Scope) relating to 40 CFR 52.21(e)). The areas are not contiguous. The North Unit and South Unit are separated by approximately 38 miles.

B. Federal regulation, 40 CFR 51.301, states "*Adverse impact on visibility* **means, for purposes of section 307, visibility impairment which interferes with the management, protection, preservation, or enjoyment of the visitor's visual experience of the Federal Class I area. This determination must be made on a case-by-case basis taking into account the geographic extent,** intensity, duration, frequency and time of visibility impairments and how these factors correlate with (1) times of visitor use of the Federal Class I areas, and (2) the frequency and timing of natural conditions that reduce visibility. This term does not include effects on integral vistas." (Emphasis added) Combining the three units of TRNP into a single area for visibility analysis fails to address the "geographic extent" of any visibility impairment.

C. The North Unit is not visible from the South Unit and vice versa. The commingling of receptors from the units for a visibility analysis misrepresents the ability of a park visitor to observe features in another unit.

   Any viewable scenes outside any unit of TRNP from within the unit are "integral vistas". The effects on integral vistas are not considered when determining whether an adverse impact on visibility will occur. There are no geological features, terrain or structures in any unit of TRNP that are viewable from another unit across the land regions separating the units. For example, terrain peaks in the South Unit would have to rise at least 900 feet above terrain in the North Unit, due to the Earth's curvature, to be seen by a visitor in the North Unit. So the visual range of visitors in one unit does not include aspects of another unit.

D. The Department has treated the units as separate Class I areas for 30+ years for purposes of PSD increment consumption without objection from EPA or the FLMs prior to 2006.

E. Treating the three units as a single Class I area effectively extends Class I status to areas between the units which are classified as Class II by rule and law.

F. The units have three different names, the South Unit, the North Unit and the Elkhorn Ranch Unit.

Comment 2: (Section Three: Plan Development and Consultation)

The plan addresses the State of Minnesota's request for NDDAQ to analyze the feasibility of reducing electrical generating unit (EGU) emissions in North Dakota to less than 0.25 pounds per million Btu (lb/MMBtu) for sulfur dioxide (SO_2) and less than 0.22 lb/MMBtu for nitrogen oxides (NO_X). While NDDAQ listed reasons why it did not believe the State of Minnesota's request was supported by assessments of impact, we request that ND supply the emission rates established by the regional haze plan from EGUs across the State so we and the public can be informed of any differences between the request from Minnesota and the final requirements of the NDDAQ plan.

The U.S. Environmental Protection Agency (EPA) will need to review any discrepancy between the Minnesota regional haze plan and the North Dakota regional haze plan during its review and approval process. In addition, we agree with NDDAQ that the EPA should address the significant contribution of international emissions, particularly from power generation in Canada, in support of NDDAQ's efforts for reasonable progress.

Response: We believe the lb/10^6 Btu metric proposed by Minnesota is inappropriate since it is not based on the four factors that must be considered for a reasonable progress analysis as required by rule and law. We believe cost must be considered, especially on a dollar per deciview of improvement basis.

Comment 3: (Section Four: Monitoring Strategy and Other Implementation Plan Requirements)

We note that the language in the footnote of Table 4.1 implies that the visibility monitoring conducted under the cooperative Inter-Agency Monitoring of Protected Visual Environments (IMPROVE) system at Theodore Roosevelt NP is covering more than one Class I area. While the monitoring is at one unit, it is representative of all three units of that one Class I area.

We appreciate NDDAQ's efforts to enhance monitoring of visibility with additional collection of data. We support the ongoing efforts to collect and periodically update state-wide inventories of pollutant emissions that may contribute to the visibility impairment noted on page 24 of the Plan.

Response: The footnote to Table 4.1 will be changed.

Comment 4 (Section Five: Baseline and Natural Conditions and Uniform Rate of Progress for North Dakota Class I Areas)

As previously noted, we do not agree with the statement on page 30 that North Dakota has four distinct Class I areas. We do agree that the IMPROVE data collected at Theodore Roosevelt NP sufficiently tracks the long-term visibility conditions across the entire park and can be used for implementing the requirements of the regional haze rule.

Response: See response to Comment 1.

Comment 5: (Section Six: Sources of Visibility Impairment in North Dakota Class I Areas)

We appreciate the presentation of the Western Regional Air Partnership (WRAP) assessment of sources of visibility impairment at the two North Dakota Class I areas. In particular, Table 6.6 is a useful summary of North Dakota's contribution to impairment listed by component of light extinction. This forms a baseline to compare projected conditions in the reasonable progress section of the Plan. We ask that NDAQ clarify in the narrative that the sulfate and nitrate results are based on regional modeling using the CAMx-PSAT source apportionment tool, while the analyses of weighted emissions potential for organic carbon (OC), elemental carbon (EC), and particulate matter (PM) are based on emissions and residence time, not modeling. Figures 6.1, 6.2, 6.7, and 6.8 would be more informative if they also included 2018 results for sulfate and nitrate as is shown in the other figures for OC, EC, and PM.

Response: The Department will clarify that sulfates and nitrates are based on WRAP's tracer analysis modeling results and the results for the other pollutants are based on WRAP's weighted emissions potential analysis.

WRAP does not provide results for Case PRP18b using their tracer analysis (only Base 18b). We have included the weighted emission potential (WEP) analysis for SO_2 and NO_x that includes 2002 and PRP18b results. However, we disagree with the WRAP's estimate of oil and gas NO_x emissions in 2018.

Comment 6: (Purpose of the BART Program)

The core purpose of the BART program is to improve visibility in our Class I areas. BART is not necessarily the most cost-effective solution. Instead, BART represents a broad consideration of technical, economic, energy, and environmental (including visibility improvement) factors. We believe that it is essential to consider both the degree of visibility improvement in a given Class I area as well as the cumulative effects of improving visibility across all of the Class I areas affected.

Response: The determination of Best Available Retrofit Technology (BART) is based on the assessment of five factors: 1) Cost of compliance, 2) the energy and nonair quality environmental impacts of compliance, 3) any existing pollution control technology in use at the source, 4) the remaining useful life of the source and 5) the degree of improvement in visibility which may be reasonably be anticipated to result from the use of such technology (CAA, Sec. 169A(g)(2)). The Department has considered all five factors in its BART determinations. EPA, in Step 5 of the BART Guideline states "…you are free to determine the weight and significance to be assigned to each factor". In determining BART, visibility improvement was generally not weighted as heavily as the cost of compliance because we believe the single source modeling required by the BART guideline does not give a true representation of the degree of improvement in visibility **which may reasonably be anticipated to result from the use of the technology**.

We believe the cumulative visibility effects analysis promoted by DOI is scientifically unsound and not in accordance with rule or law. Adding the maximum improvement value (or 98th percentile) at one Class I area to the maximum improvement at another Class I area does not account for these maximums happening at different times. In addition, DOI has not defined which Class I areas should be added together to achieve the cumulative impact. This makes the analysis arbitrary. The single source modeling under BART does not provide a realistic estimate of visibility improvement of a given technology. Creating a "cumulative effects" analysis based on the flawed BART analysis only compounds the inaccuracy and misleads the reader of the SIP. In addition, the BART Guideline only requires an evaluation of the change at each receptor. It does not require adding these changes together.

Comment 7: (Five-Step BART Process)

Step 1: IDENTIFY AVAILABLE RETROFIT CONTROL TECHNOLOGIES
Except for Great River Energy's (GRE's) analysis for NO_x from Coal Creek, all of the other SO_2 and NO_x analyses included a reasonable suite of options.

We also have some general comments that apply to all of the PM_{10} analyses. We believe that the BART analyses are deficient in that they neither address upgrades to the existing Electrostatic Precipitators (ESPs) or propose limits that realistically reflect the capabilities of those existing ESPs, as well as the proposed new baghouses, to control filterable PM. EPA's BART Guidelines (Guidelines) advise:

- "…it is important to include control options that involve improvements to existing controls and not to limit the control options only to those measures that involve a complete replacement of control equipment."
- "…for retrofitting existing sources in addressing BART, you should consider ways to improve the performance of existing control devises, particularly when a control device is not achieving the level of control that other similar sources are achieving in practice with the same device. For example, you should consider requiring those sources with electrostatic precipitators (ESPs) performing below currently achievable levels to improve their performance."

Although all of these sources have ESPs in place, none of them except Stanton Unit #1 is currently achieving a level of performance equivalent to the 0.015 lb/mmBtu proposed for ESPs at sources such as Peabody's Thoroughbred and LG&E's Trimble County projects in Kentucky. Furthermore, EPA has recently issued a permit limiting the Desert Rock facility to 0.010 lb/mmBtu filterable PM_{10}, new baghouses are being permitted at 0.009 – 0.012 lb/mmBtu in

Virginia (Virginia Hybrid Energy Center) and Wyoming (Dry Fork, WYGEN 3), and ND DOH proposed to permit the Gascoyne project at 0.012 lb/mmBtu. Instead, the limits on filterable PM_{10} proposed by NDDAQ are two – to – three times the emission rates measured by stack testing and cited by NDDAQ. While we understand that a certain "safety margin" must be allowed, we believe that the BART limits should be set to encourage continued good operation and maintenance of the pollution control equipment.

Response: The comment regarding the suite of options evaluated for NO_x controls at Coal Creek will be addressed later under the specific comments on the Coal Creek BART determination.

Regarding BART for PM at the BART eligible sources, in 2008 the emission rate at these sources ranged from 0.004 lb/10^6 Btu to 0.015 lb/10^6 which is generally comparable to levels achieved under BACT. The Department evaluated recent stack tests at the various power plants and found that emissions could vary up to 0.061 lb/10^6 Btu at Leland Olds Unit 1. The variation in the PM emission rate is probably due to a variation in the coal combusted (i.e. higher ash, different ash resistivity, etc.) and/or variations in the boiler and ESP operations. Sources must be able to comply with a BART limitation at all times unless specifically exempted. The Department chose to reduce the current allowable down from 0.10 lb/10^6 to 0.07 lb/10^6 Btu. This allows the sources to maintain continuous compliance yet requires the source to assure the ESP is working properly. The Department also reviewed the effect of PM from the BART sources on visibility. Based on the maximum 24-hour emission rate for the baseline period (5 years) the maximum impact was 0.027 deciviews (98th percentile). This amount of impact is considered very small and inconsequential. The newest ESP at the BART sources is 30 years old. The Department's review found that it was not cost effective to replace them and any improvement would not provide appreciable visibility improvement. We have concluded that 0.07 lb/10^6 Btu is a reasonable emission limit after considering the five statutory factors.

Comment 8:

Step 3: EVALUATE EFFECTIVENESS OF REMAINING CONTROL TECHNOLOGIES The ability of SCR to reduce emissions, as assumed by NDDAQ, was inconsistent and sometimes underestimated. For example, for the LNB/OFA+SCR option, GRE, Basin Electric Power Cooperative (BEPC), and NDDAQ sometimes assumed 0.07 lb/mmBtu for all averaging periods. However, for example, the WY Department of Environmental Quality has issued permits for new EGUs requiring that they meet 0.05 lb/mmBtu over averaging periods of 24-hours and 30-days. Furthermore, EPA's Clean Air Markets (CAM) data (Appendix A) and vendor guarantees show that SCR can typically meet 0.05 lb/mmBtu (or lower) on an annual average basis. GRE, BEPC, and NDDAQ have not provided any documentation or justification to support the higher values used in their analyses. Our review of operating data (Appendix A) suggests that a NO_X limit of 0.06 lb/mmBtu is appropriate (with an adequate "safety-margin") for LNB/OFA+SCR for a 30-day rolling average, and 0.07 lb/mmBtu for a 24-hour limit and for modeling purposes, but a lower rate (e.g., 0.05 lb/mmBtu or lower) should be used for annual average and annual cost estimates. When the annual NO_x reductions are underestimated, the cost-effectiveness of the control option is negatively affected.

Response: The 0.05 lb/10^6 Btu limit in Wyoming was for the Dry Fork Plant which is a new plant and has not demonstrated that it can meet that limit.

DOI claims that SCR can achieve 90% removal efficiency. The Department believes this is true for new units but not for retrofits. The EPA Air Pollution Control Cost Manual states "In practice, SCR systems operate at efficiency in the range of 70% to 90%." EPA's Air Pollution Control Technology Fact Sheet for SCR states "SCR is capable of NO_x reduction efficiencies in the range of 70% to 90%." In the ANPR for the Four Corners Power Plant (Federal Register 8/28/09) EPA states "APS estimated that SCR could achieve NO_x control of approximately 90% or greater from the baseline emissions. For new facilities, 90% or greater reduction in NO_x from the SCR can be reasonably expected. See May 2009 White Paper on SCR from Institute of Clean Air Companies. For SCR retrofits on an existing coal-fired power plant, Arizona Department of Environmental Quality (ADEQ) determined that 75% control from SCR (following upstream reductions by LNB) was appropriate for the Coronado Generating Station in Arizona. Based on this data, EPA has determined that an 80% control efficiency for SCR alone, rather than the 90+% control assumed by APS, is appropriate". The Department believes 80% is a reasonable estimate that allows the source to comply with the expected emission limit on a continuous basis.

Comment 9:

Step 4: EVALUATE IMPACTS AND DOCUMENT RESULTS

The cost of SCR was consistently overestimated. EPA's BART Guidelines recommend use of the OAQPS Control Cost Manual. Neither Minnkota Power Cooperative (Minnkota), GRE, BEPC, nor NDDAQ provided justification or documentation for their cost estimates. We were not provided with any vendor estimates or bids, and none used the recommended Control Cost Manual. This resulted in much-higher SCR costs than suggested by available literature (see Appendix B cost summaries) which shows SCR costs ranging from \$50 - \$267/kW. As recommended by the BART Guidelines, we applied the OAQPS Control Cost Manual to the EGUs and derived costs that fell within the Appendix B cost-survey range. As a result, we believe that capital and annual costs are overestimated by NDDAQ.

According to EPA's BART Guidelines, "the basis for equipment cost estimates should be documented, either with data supplied by an equipment vendor (i.e., budget estimates or bids) or by a referenced source (such as the OAQPS Control Cost Manual, Fifth Edition, February 1996, 453/B-96-001). In order to maintain and improve consistency, cost estimates should be based on the OAQPS Control Cost Manual, where possible. The Control Cost Manual addresses most control technologies in sufficient detail for a BART analysis. The cost analysis should also take into account any site-specific design or other conditions identified above that affect the cost of a particular BART technology option."

EPA's belief that the Control Cost Manual should be the primary source for developing cost analyses that are transparent and consistent across the nation and provide a common means for assessing costs is further supported by this November 7, 2007, statement from EPA Region 8 to NDDAQ:

> The SO_2 and PM cost analyses were completed using the CUECost model. According to the BART Guidelines, in order to maintain and improve consistency, cost estimates should be based

on the OAQPS Control Cost Manual. Therefore, these analyses should be revised to adhere to the Cost Manual methodology.

We are especially concerned about the lack of justification and support for the estimates of costs for reheating the exhaust gas streams to facilitate addition of "tail-end" SCR. Reheat costs are a critical issue affecting the economic feasibility of SCR, and, even in those cases where some data were presented (by GRE), it was still not adequate for us to be able to understand the assumptions that formed the bases for the natural gas usage estimates. Furthermore, we are concerned that the costs of catalyst, ammonia, electricity, and natural gas were inflated beyond what we typically see, or what is projected by the Energy Information Administration (EIA) with respect to future natural gas prices. Finally, we are concerned that this critical cost was simply scaled from a few examples and applied to other SCR analyses—we believe that it deserves individual analyses specific to each case.

Response: The DOI used the EPA Air Pollution Control Cost Manual (February 1996) to estimate the capital cost and operating costs for the SCR system. The DOI did not use the most current version of this manual which is dated January 2002. The EPA Air Pollution Control Cost Manual (both versions) is significantly out-of-date for estimating costs for SCR. This can be seen from the recently published results of EPA's review of the Four Corners Power Plant BART analysis. In the Advanced Notice of Proposed Rulemaking (August 28, 2009), EPA published the Consultant's, EPA's and the National Park Service's estimate of the cost for NO_x controls. The annualized cost of SCR was as follows:

Unit	Consultant	EPA	NPS
1	$22,297,000	$16,599,600	$2,983,000
2	$23,634,000	$17,851,500	$3,052,010
3	$23,173,000	$16,962,000	$3,497,117
4	$55,755,000	$39,810,900	$9,838,997
5	$55,755,000	$39,810,900	$9,213,942

The NPS cost estimate is 4-6 times lower than EPA's estimate.

For SCR alone the cost effectiveness was:

Unit	Consultant ($/ton)	EPA Cost ($/ton)	NPS Cost ($/ton)
1	4,343	3,758	1,558
2	5,484	4,803	1,469
3	4,582	3,646	1,684
4	4,872	4,341	1,185
5	4,872	4,330	1,357

It would appear the NPS is underestimating annualized SCR costs by as much as a factor of 6 and cost effectiveness by as much as a factor of 3. The discrepancy between the annualized cost and the cost effectiveness is apparently due to the NPS overestimating the effectiveness of SCR.

Based on this apparent underestimation, it appears the costs provided by the consultants and the Department's estimates are similar to EPA estimates and are reasonable. Any estimate by the FLM of cost on a dollar per deciview basis would be similarly flawed.

As pointed out earlier, the OAQPS Control Cost Manual is out-of-date. EPA accepted estimates based on the CUE Cost Model for the Four Corners Power Plant BART analysis. Since the OAQPS Control Cost Manual is out-of-date and drastically underestimates control costs, we believe the CUE Cost Model provides a more realistic estimate of the costs.

Comment 10: (Step 5: Visibility Improvement)

A) DOI believes it is appropriate to consider both the degree of visibility improvement as well as cumulative effects.

B) DOI is concerned that the Department did not provide the total improvement for each BART option.

Response: The total improvement under BART is not the best metric for addressing visibility associated with each option since the single source modeling under BART overpredicts (by a factor of 5-7) the actual improvement in North Dakota. Incremental differences in improvement provides an easy way to evaluate the visibility improvement benefits of one option over another. The difference is equivalent to the total improvement of one option minus the total improvement of the other option. Providing the total improvement will mislead the reader of the SIP because of the overprediction. However, this information can be extracted from the analyses conducted by the operators of the BART sources.

C) DOI is concerned about the difference in their modeling for Leland Olds Unit 2 and the Department's and Basin Electric's modeling results (the latter two sets of results agree closely).

Response: There are bound to be differences in modeling results when different model settings and options are used as well as different receptor grids. One error noted in the DOI modeling results was the input for the maximum 24-hour SO_2 emission rate for Unit 2. DOI used 17,610 lb/hr plus 1,581 lb/hr for sulfate. Unit 2 had a maximum 24-hour SO_2 (includes SO_4) of 12,205 lb/hr during the baseline period (2000-2004). DOI apparently used an SO_2 + SO_4 emission rate based on maximum future sulfur content. This is incorrect since current visibility conditions (12,205 lb/hr) are compared to conditions after controls are applied. The BART Guideline states "Use the 24-hour average actual emission rate from the highest emitting day of the meteorological period modeled (for the pre-control scenario)". The meteorological data used by the Department is from 2000-2004. Use of potential future uncontrolled emissions for the pre-control scenario is inconsistent with the BART guideline. The Department also noted that this error carried over into the emission rates for other pollutants. This error will provide a much greater improvement in visibility as found by the DOI.

Comment 11: It appears to be more beneficial to reduce NO_x than to reduce SO_2 in this cool climate.

Response: The Department does not necessarily agree with this statement. There are situations in North Dakota where reduction in NO_x has very little impact on visibility. This can be seen from the AVS I analysis. A 65% reduction NO_x (2,356 tpy) only provided a 0.01 deciview improvement in the average of the 20% worst days.

Comment 12: DOI recommends more emphasis on the dollar per deciview metric.

Response: There was no established data base for this metric when the BART analyses were developed and when the Department was making its decisions. Even the DOI's data is not very useful since the EPA has not approved the BART determinations in that database. Again, the single source modeling does not reflect the true visibility improvement. It may be more realistic in some states than in others. Therefore, the comparison of $/deciview in North Dakota to $/deciview in another State is not an apples-to-apples comparison. The Department has considered the incremental visibility improvement between BART options. We believe this is the best metric given the limitations of single source modeling to provide realistic estimates of visibility improvement.

Comment 13: For several units, NDDOH is proposing alternative sulfur dioxide (SO_2) limits that are similar to the presumptive BART limits because they allow a source to choose between a limit in terms of pounds of emissions per million Btu of heat input, or percent reduction of that pollutant. While EPA presented its BART Guidelines for SO_2 in that format, we do not believe that it was EPA's intention to allow the source to choose the more favorable limit. By definition, BART represents the highest degree of control that meets the five-factor test. Where NDDOH has determined that a lb/mmBtu limit is reasonable, it should require that that limit be met. Similarly, where NDDOH has determined that a percent reduction limit is reasonable, it should require that that limit be met. If both limits are determined to be reasonable, then to allow the source to choose only one clearly does not represent the most stringent reasonable degree of control. Therefore, where NDDOH has proposed alternative limits, both should be required.

There is also a fundamental problem with setting only a percent-reduction limit on SO_2 emissions. If fuel sulfur content increases, emissions can increase correspondingly. Unless sulfur content is limited, or a cap is placed on mass emissions (e.g., lb/hr, tons/yr as proposed by Wyoming, for example), the actual amount of SO_2 emitted is unlimited.

Response: The DOI has requested that the sulfur dioxide limitations be written as 95% reduction and 0.15 lb/10^6 Btu instead of 95% reduction or 0.15 lb/10^6 Btu. Coal quality data suggests that the source may not be able to comply with the 0.15 lb/10^6 Btu limit when the maximum sulfur coal is received. This would make the requested standard impossible to meet for high sulfur coal. The BART guidelines (40 CFR 51, Appendix Y, Section IV.E.4) states "you must require 750 MW power plants to meet specified levels of SO_2 of either 95 percent control **or** [emphasis added] 0.15 lb/10^6 Btu". The guidance does not indicate both standards apply. In addition, the BART presumptive levels are not applicable to any source in North Dakota except for NO_x at Coal Creek Station.

The DOI has also asked that a mass per unit of time limit be placed on the permit for SO_2. The Department believes this is unnecessary since the Department's evaluation of visibility impacts was based on full load and worst case sulfur (i.e. highest 24-hour emissions). The Department asked the EPA if a mass per unit of time limit (24-hour basis to ensure the accuracy of the modeling) was necessary in the permit that establishes the BART limits. In a November 21, 2005 response from Laurel Dygowski of Region 8, it was stated "we think that a 24-hour limit is unnecessary and may not be of much value". Based on EPA's guidance and the Department's determination that mass per unit of time units are not necessary, the Department will not include such limits in the permit that establishes the BART limits.

Comment 14: DOI does not believe Heskett Unit 2 should be exempt from the BART requirement.

Response: The Department is reevaluating the status of Heskett Unit 2. This unit will be addressed in a supplement to this SIP revision.

Comment 15: DOI believes the 70% reduction requirement at Heskett Unit 2 is misleading.

Response: The 70% reduction is a requirement that was placed in the draft Permit to Construct. The calculations that were provided are accurate based on the coal quality expected. The Department will clarify that the permit requirement (70% reduction) is not an actual reduction from current emissions.

Coal Creek BART Determination

Comment 16: Low NO_x burners and Over-Fire Air should have been considered coupled with SCR.

Response: The Department evaluated SCR at an emission rate of 0.043 $lb/10^6$ Btu (annual average) which is equivalent to 0.05 $lb/10^6$ Btu on a 30-day rolling average basis. This is the same as the lowest emission rate in the RBLC. We believe a lower emission rate is not achievable on a continuous basis. Because Coal Creek is already equipped with LNB and a form of overfire air, the modifications of these systems is not expected to reduce emissions below 0.043 $lb/10^6$ Btu.

Comment 17: NDDAQ is proposing upgrading the existing wet scrubber to limit SO_2 emissions to 0.15 lb/mmBtu **or** 95% reduction on a 30-day rolling average basis. The proposed scrubber upgrades will each result in an approximately one dv improvement in visibility at Theodore Roosevelt NP and 1.9 dv cumulatively when Lostwood WA is included. We commend NDDAQ for the proposed new wet scrubber, but recommend that the limits require **both** 95% control **and** 0.15 lb/mmBtu, as well as specific caps on emissions.

Response: The Department's BART determination is based on upgrading the existing wet scrubber to 95% efficiency, not the addition of a new wet scrubber. See response to Comment 13 regarding the BART limit.

Comment 18: NDDAQ is proposing LNB + SOFA at 0.17 lb/mmBtu on a 30-day rolling average basis as BART for NO_X. As a result, visibility would improve by 0.10 dv at Lostwood and 0.19 dv cumulatively.

Response: See response to Comment 6, Paragraph 2.

Comment 19: NDDAQ has underestimated the effectiveness of SCR at only 80% control efficiency.

Response: See response to Comment 8.

Comment 20: NDDAQ has overestimated the costs of SNCR and SCR. Many of the costs associated with SNCR and SCR presented by GRE and NDDAQ were not supported by GRE's documentation. Costs associated with lost ash sales and ash disposal were not adequately justified. More reliance should be placed upon use of the EPA Control Cost Manual when the source fails, as GRE did, to provide sufficient supporting documentation of its costs. Our application of the EPA Control Cost Manual yielded much lower cost estimates for SNCR and SCR.

Response: See response to Comment 9.

Concerning the inclusion of sunk costs of ash sales infrastructure, an assessment of the effect of removing sunk costs from the calculations has been performed and added to the BART determination. If the sunk costs for the ash sales infrastructure are disregarded, then the annualized cost for SNCR would be $21,750,000; the cost effectiveness would be $8,122 per ton; and the incremental cost would be $19,692 per ton. This change improves the favorability of the SNCR alternative by only 5%, an insignificant improvement that does not change the choice for BART.

On the matter of the possibility of lost ash sales, DOI stated elsewhere in its comments: "If ash sales are not adversely affected, addition of SNCR becomes a reasonable BART selection." However, neither DOI, EPA nor others have provided evidence to support the opinion that SNCR and its associated use of ammonia will not negatively impact GRE's ash sales; in fact, there is some evidence to the contrary. GRE emails dated 8/8/08 and 8/17/08 provide additional information on this issue, as does a summary of a University of Kentucky study on the matter. After considering all the information available, NDDAQ reached the following conclusions.

- SCR and SNCR use at Coal Creek Station will likely result in ammonia in the fly ash.
- The level of ammonia in the fly ash cannot be predicted with a reasonable certainty.
- The maximum level of ammonia in fly ash that would still avoid negative impacts on the salability of the ash cannot be predicted.

Therefore, NDDAQ cannot determine with reasonable certainty that SCR or SNCR will not result in a level of ammonia in the ash that could reduce or eliminate future ash sales. Any regulator who determines that SCR or SNCR will not jeopardize ash sales would be obligated to present the evidence in support of that position. While another regulator might determine that even a small improvement in visibility is worth GRE taking the risk of lost ash sales, making a wrong decision will inflict a significant financial penalty on GRE and send ash to a landfill, or be treated as a hazardous waste (depending on current rule development), instead of it being used beneficially. Having considered all of the information available, the NDDAQ BART determination on this matter remains unchanged.

Furthermore, in a BART and PSD analysis for the Omaha Public Power District Nebraska City Station Unit #1 coal boiler (Construction Permit Number CP07-0049, 2/26/09 fact sheet, pg. 17), Nebraska DEQ determined SCR was not BART in part because … "ammonia used in the system would cause the ash to be contaminated, thereby jeopardizing the current beneficial reuse of a portion of the ash produced by NCS Unit 1."

Comment 21: We conclude that SNCR is BART for control of NO_X emissions from GRE Coal Creek Units #1 and #2.

Response: See Comment 20 and response concerning lost ash sales.

Comment 22: NDDAQ has not adequately considered the visibility benefits of the control strategies it evaluated.

Response: Tables showing the visibility impacts of the cost effective control strategies will be added to the GRE Coal Creek BART analysis.

Comment 23: NPS' analysis of addition of SNCR indicates that visibility would improve by 0.17 dv at Lostwood and 0.32 dv cumulatively. This yields a cost-effectiveness of $17.2 million per dv at Lostwood WA and $9.2 million per dv cumulatively when Theodore Roosevelt NP is included, which we believe to be reasonable based upon BART determinations and proposals we have seen nationwide to date. NPS' estimates for addition of SNCR show cost-effectiveness values below the $17 - $21 million per cumulative dv that NDDAQ accepted for adding SNCR at Stanton #1. Considering that the BART program is intended to improve visibility, it follows that any cost-effectiveness value below the costs per dv accepted by NDDAQ at Leland Olds #1 and Stanton should also be acceptable at Coal Creek.

Response: See response to Comment 6.

Stanton Unit 1 Bart Determination

Comment 24: On page 15 of the comments, the DOI states that "Great River Energy (GRE) operates the 256 MW Stanton Station near Stanton, ND."

Response: The nameplate capacity of the Stanton Station is 200 MWe, not 256 MW as stated by DOI. The National Park Service was informed by the Department in an October 21, 2009 email that the nameplate capacity of the Stanton Station is 200 MWe. It should be noted that the BART determination is being conducted for Stanton Station Unit 1, not the entire Stanton Station (which consists of Stanton Station Unit 1 and Unit 10). Stanton Unit 1 can supply steam that will produce 140 – 170 MWe.

Comment 25: On page 16 of the comments, the DOI states, "We believe that higher control efficiency is warranted for both the lignite and PRB sub-bituminous scenarios". The DOI goes on to state that a facility burning coal with an uncontrolled SO_2 emission rate of 2.4 lb/MM Btu for lignite and 1.6 lb/MMBtu on PRB "should be capable of at least 93% control and achieve an emission limit of 0.09 lb/MMBtu on a 30-day rolling average basis[11]". Footnote 11 in the DOI comments states, "Please see the entry in Appendix D for the permit issued by Wyoming to Black Hills Power for its WYGEN3 project".

Response: The DOI states a SD/FF at Stanton #1 "should be capable of" at least 93% control and an emission limit of 0.09 lb/MMBtu on a 30-day rolling average basis. The DOI attempts to support this position by referencing the WYGEN3 facility permit. Although the WYGEN3 facility does have a 0.09 lb/MMBtu SO_2 emission limit, according to the EPA RACT/BACT/LAER clearinghouse, the 0.09 lb/MM Btu SO_2 emission limit is on a <u>12-month rolling average</u> basis, not a <u>30-day rolling average</u> basis. Also, the RACT/BACT/LAER clearinghouse does not list a required SO_2 removal efficiency. If the WYGEN3 facility burns low-sulfur coal, the facility could comply with the 0.09 lb/MMBtu emission limit with SO_2 control efficiencies below 90%. Furthermore, it is the Department's understanding that the WYGEN3 facility has yet to operate and demonstrate that the SO_2 emission limit can be achieved. Based upon these facts, the WYGEN3 facility permit does not support the DOI position that a SD/FF at Stanton Station Unit 1 "should be capable of" at least 93% control and an emission limit of 0.09 lb/MMBtu on a 30-day rolling average basis.

The Department maintains the position that a SD/FF operating at Stanton Station Unit 1 is capable of achieving an SO_2 control efficiency of 90%.

Comment 26: On page 16 of the DOI comments, the DOI states, "Because the larger Stanton Unit #10 also located at this site is achieving less 0.06 lb/MMBtu on an annual basis (presumably burning PRB coal) using the same SD/FF technology proposed for Stanton Unit #1, NDDAQ should explain why a newer installation of that technology at Stanton #1 cannot perform as well, at least on PRB coal".

Response: The DOI incorrectly states that Stanton #10 is larger than Stanton #1. In fact, Stanton #10 (with a heat input of approximately 642 MM Btu/hr) is approximately 2.8 times <u>smaller</u> than Stanton #1 (with a heat input of approximately 1,800 MM Btu/hr).

The DOI states that Stanton #10 emitted SO_2 at an emission rate of 0.06 lb/MM Btu and asks the Department to explain why Stanton #1 cannot perform as well as Stanton #10 when burning PRB coal. Although the Stanton #10 facility has recently emitted SO_2 at an emission rate of 0.06 lb/MM Btu, based upon the average sulfur content of the coal burned the SO_2 removal efficiency at Stanton #10 is estimated to be approximately 90%. The dry scrubber technology proposed as BART for Stanton #1 is expected to achieve an SO_2 control efficiency of 90%, so Stanton #1 <u>will be</u> expected to perform as well as Stanton #10.

Comment 27: On page 16 of the DOI comments, the DOI states, "It is likely that increasing the SD/FF efficiency to achieve 0.09 lb/mmBtu would be even more cost effective on a $/ton basis."

Response: The DOI provides no basis for this comment. The Department maintains the position that 90% control is a reasonable control efficiency for a SD/FF system and that the Stanton Station Unit 1 would not be able to meet an SO_2 emission limit of 0.09 lb/MM Btu when combusting higher sulfur coals.

Comment 28: On page 17 of the DOI comments, the DOI states, "We recommend limits of 0.09 lb/mmBtu and 93% reduction on a 30-day rolling average for both fuels based upon recent determination by other states for EGUs burning coals with similar uncontrolled emissions. Even if coal quality deteriorates to the anticipated worst-case 2.4 lb/mmBtu, 96% control would still meet the 0.09 lb/mmBtu limit. We also recommend short and long-term absolute (e.g., lb/hr, tpy) caps on emissions to insure that emissions will not increase greatly over time". The DOI reiterates this comment on page 20 of the DOI comments.

Response: DOI has requested that the sulfur dioxide limitations be written as 93% reduction <u>and</u> 0.09 lb/MM Btu for both fuels instead of 90% reduction <u>or</u> 0.16 lb/MM Btu for PRB <u>or</u> 0.24 lb/MM Btu for lignite. Coal quality data suggests that the source would not be able to comply with the 0.09 lb/MM Btu limit when the maximum sulfur content coal is received and emissions are controlled at 90%. This would make the requested standard impossible to meet for high sulfur coal with a 90% reduction requirement. The DOI suggests that the facility can simply control at efficiencies greater than 90% (i.e. 96%); however, the Department's position is that a SD/FF operating at Stanton Station #1 is capable of 90% SO_2 control on an on-going basis, not greater than 90% control as suggested by DOI.

The BART guidelines (40 CFR 51, Appendix Y, Section IV.E.4) states, "you must require 750 MW power plants to meet specified levels of SO_2 of either 95 percent control <u>**or**</u> [emphasis added] 0.15 lb/10^6 Btu". The guidance does not indicate both standards apply. In addition, the BART presumptive levels are not applicable to this source.

The DOI has also asked that a mass per unit of time limit be placed on the permit for SO_2. The Department believes this is unnecessary since the Department's evaluation of visibility impacts were based on full load. The Department asked the EPA if a mass per unit of time unit (24-hour basis to ensure the accuracy of the modeling) was necessary in the permit that established the BART limits. In a November 21, 2005 response from Laurel Dygowski of Region 8, it was stated, "We think that a 24-hour limit is unnecessary and may not be of much value". Based on EPA's guidance and the Department's determination that mass per unit of time units are not necessary, the Department will not include such limits in the permit that established the BART limits.

Comment 29: On page 17, the DOI states, "We believe that NDDAQ should have included SOFA with tail-end SCR with reheat in its analysis".

Response: The Department analyzed SCR with reheat in the BART analysis. A 90% control efficiency for SCR with reheat was assumed. For retrofits, the Department believes that a 90% control efficiency for SCR with reheat is highly optimistic and that 80% control is reasonable. It should be noted that conducting the BART analysis using an 80% control efficiency would make the cost of SCR with reheat even more cost prohibitive.

In the Department's judgment, SOFA with SCR with reheat would not attain greater than 90% NO_x control at Stanton #1. Since SOFA with SCR with reheat would be more expensive than SCR with reheat (which has already been determined to be cost prohibitive assuming a 90% control efficiency), it can be concluded that an analysis of SOFA with SCR with reheat would also be considered to be cost prohibitive.

Comment 30: On pages 18 and 20 the DOI indicates that the expected costs for SCR with reheat included in the BART analysis for Stanton #1 are higher than the cost estimates prepared by the DOI. The DOI requests that the Department document and justify the SCR with reheat cost estimate.

Response: The DOI requests that the Department document and justify the SCR with reheat cost estimate for Stanton #1. The Department considers the cost estimate of SCR with reheat submitted with the GRE BART analysis to be extensively documented and the Department has verified the cost estimates.

The DOI states that the expected costs for SCR with reheat included in the BART analysis for Stanton #1 are higher than the cost estimates prepared by the DOI. See response to Comment 9.

Comment 31: On page 21 of the comments, the DOI states, "We believe that SCR may represent BART, especially when the modeling issues identified in other reviews are resolved".

Response: The Department has eliminated high-dust SCR as technically infeasible and low-dust SCR with reheat has been eliminated based on cost. The DOI has questioned the Department's cost estimates for SCR with reheat and the Department has demonstrated that the costs as presented are reasonable (see response to Comment 9). Based upon a consideration of all of the factors, the Department maintains the position that SCR does not represent BART at Stanton Station Unit 1.

Leland Olds Unit 1 BART Determination

Comment 32: NDDAQ did not evaluate the impact of the new wet scrubber at Unit 1 versus the baseline condition.

Response: The Department evaluated the difference in visibility impact between the top two SO_2 control technologies, a wet scrubber and spray dryer. As indicated by the BART Guideline, Step 5, a determination of the net visibility improvement is to be made. Our analysis is consistent with the BART Guideline. The most efficient control option (wet scrubber) was selected as BART. The amount of visibility improvement versus the baseline may be extracted from BEPC's analysis. The Department did not present this result since we believe it is incorrect and misleads the reader.

Comment 33: DOI recommends that the SO_2 limit be written as 0.15 lb/10^6 Btu and 95% reduction.

Response: See response to Comment 13.

Comment 34: DOI believes SOFA + SCR can achieve 83% NO_x removal.

Response: As pointed out in the Advanced Notice of Proposed Rulemaking for the Four Corners Power Plant, the Arizona DEQ determined that 75% control was appropriate following low NO_x burners at the Coronado Generating Station. Leland Olds 1 is equipped with low NO_x burners. We believe 75% reduction for the retrofit of a 43 year old plant is appropriate. Reducing the emission rate to 0.05 lb/10^6 Btu achieves 212 tons per year additional NO_x reduction. The cost effectiveness is then $8,888/ton to $12,784/ton. These costs are still considered excessive and SCR + SOFA is not BART.

Comment 35: NDDAQ did not evaluate the visibility benefits of any of the technically feasible options except for the proposed basic SOFA + SCR.

Response: The cost analysis eliminated SCR, coal reburn + SCR, coal reburn + SOFA and SNCR + boosted SOFA on either a very high cost effectiveness basis or a very high incremental cost basis. This left SOFA + SNCR as the most efficient control option. This option was then modeled to determine the visibility effects.

Comment 36: NDDAQ is proposing addition of a new wet scrubber to limit SO_2 emissions to 0.15 lb/mmBtu **or** 95% reduction on a 30-day rolling average basis. We have estimated that the proposed new wet scrubber will result in an approximately 1.2 dv improvement in visibility at Theodore Roosevelt NP and 2.4 dv cumulatively when Lostwood WA is included. We commend NDDAQ for the proposed new wet scrubbers, but recommend that the limits require **both** 95% control **and** 0.15 lb/mmBtu, as well as specific caps on emissions.

Response: See response to Comment 13.

Comment 37: Based upon NDDAQ's analysis, addition of the proposed basic SOFA+SNCR to LOS #1 yields a cost-effectiveness of $25.6 million per dv at Theodore Roosevelt NP and $13.2 million per dv cumulatively when Lostwood WA is included. NDDAQ has not adequately considered the visibility benefits of the control strategies it evaluated. NPS' analysis of addition of basic SOFA+SCR with reheat yields a cost-effectiveness of $12.6 – $32.3 million per dv cumulatively. We would normally consider costs above $20 million/dv to be above the average that most states/source are proposing, but believe that these results warrant further analysis, as we will discuss in more detail with respect to LOS #2.

Response: SOFA + SCR has an estimated cost of $8,888 - $12,784/ton of NO_x removed. The incremental cost would be approximately $15,748/ton to $25,319/ton over the next most efficient option. It is clear that SOFA + SCR, or SCR alone, is not cost effective for this unit.

Comment 38: NDDAQ underestimated the effectiveness of adding SCR to LOS #1. Outlet emissions projected by NDDAQ for SCR at 0.07 lb/mmBtu represent only a 75% SCR control efficiency We believe that a combination of combustion controls (e.g., SOFA) plus SCR can achieve 0.05 lb/mmBtu, and represents BART.

Response: See response to Comment 8. This is consistent with other BACT determinations, especially for retrofits.

Comment 39: NDDAQ overestimated the costs associated with adding SCR to LOS #1.Our application of the EPA Control Cost Manual yielded much lower cost estimates for SCR. Many of the costs associated with SCR presented by BEPC and NDDAQ were much higher than we have seen presented at similar facilities and were not supported by BEPC's documentation. More reliance should be placed upon use of the EPA Control Cost Manual when the source fails, as BEPC did for LOS, to provide sufficient supporting documentation of its costs.

Response: See response to Comment 9.

Leland Olds Unit 2

Comment 40: DOI suggests we investigate the differences in their modeling results and the Department's and BEPC results.

Response: The Department has investigated the DOI modeling – See response to Comment 10(c). The DOI modeling is not consistent with the BART Guideline. The Department's and BEPC modeling is consistent with the guideline.

Comment 41: NDDAQ is proposing to limit SO_2 emissions to 0.15 lb/mmBtu **or** 95% reduction on a 30-day rolling average basis. We recommend 0.15 lb/mmBtu **and** 95% reduction on a 30-day rolling average basis.

Response: See response to Comment 13.

Comment 42: We re-modeled LOS #2 assuming that the new wet scrubber would reduce SO_2 emissions to 0.15 lb/mmBtu and held all other emissions to their baseline rates. Our results estimate that the scrubber would improve visibility by 5.6 dv at Theodore Roosevelt NP and 9.4 dv cumulatively when Lostwood WA is included.

Response: See response to Comment 10(c). The much higher future emission rate, which is not consistent with the BART Guideline which requires use of the baseline emission rate, yielded the higher inaccurate result.

Comment 43: We agree with NDDAQ's estimates of control effectiveness, but suggest that, if ASOFSA can reduce emissions to 0.5 lb/MMBtu as estimated by NDDAQ, then addition of SCR at 90% as assumed by NDDAQ could bring emissions down to 0.05 lb/mmBtu.

Response: As pointed out in our response to Comment 8, 80% efficiency is a better number for retrofit of SCR. The Department did use 90% efficiency for SCR + ASOFA.

Comment 44: NDDAQ overestimated the costs associated with adding SCR to LOS #2.Our application of the EPA Control Cost Manual yielded much lower cost estimates for SCR. Many of the costs associated with SCR presented by BEPC and NDDAQ were much higher than we have seen presented at similar facilities and were not supported by BEPC's documentation. More reliance should be placed upon use of the EPA Control Cost Manual when the source fails, as BEPC did for LOS #2, to provide sufficient supporting documentation of its costs.

Response: See response to Comment 9.

Comment 45: We re-modeled LOS #2 and estimate that ASOFA + SCR would improve visibility by 2.3 dv at Theodore Roosevelt NP and 4.1 dv cumulatively when Lostwood WA is included. Our higher control-effectiveness results show that we are estimating that removing a ton of NO_x has greater benefits than estimated by BEPC/NDDAQ.

Response: The DOI modeling is inaccurate – see response to Condition 10(c). We believe the cumulative results are inappropriate – see response to Comment 6, Paragraph 2.

Comment 46: NPS' analysis of addition of ASOFA+SCR with reheat and using NDDAQ modeling results yields a cost-effectiveness of $4.0 – $9.6 million per dv at Theodore Roosevelt NP and $2.3 – $5.5 million per dv cumulatively when Lostwood WA is included. We believe that our cost estimates indicate that addition of SCR with reheat is reasonable based upon BART determinations and proposals we have seen nationwide to date.

Response: See response to Comments 10(c), Comment 6 and Comment 9.

Comment 47: The great disparity between modeling results produced by BEPC/NDDAQ and NPS requires resolution.

Response: See response to Comment 10(c).

M.R. Young Station Unit 1

Comment 48: We have estimated that the proposed new wet scrubber will result in an approximately 1.8 dv improvement in visibility at Theodore Roosevelt NP and 3.2 dv cumulatively when Lostwood WA is included. We commend NDDAQ for the proposed new wet scrubbers, but recommend that the limits require **both** 95% control **and** 0.15 lb/mmBtu, as well as specific caps on emissions.

Response: See response to Comment 13.

Comment 49: NDDAQ proposes that NO_x emissions be limited to 2,070.2 lb/hr on a 24-hour rolling average basis during startup. We recommend that NDDAQ limit the mass emission rate (e.g., lb/hr) to the rate under normal operation.

Response: The proposed limit is under normal operating conditions without the ASOFA and SNCR, since the SNCR cannot be operated until the proper boiler temperature is reached. The actual startup emissions will be much higher (>1.0 lb/10^6 Btu). Therefore, limiting startup emissions based on normal operations with SNCR ($\leq$0.35 lb/10^6 Btu) will provide no relief to the source during startup.

Comment 50: NDDAQ underestimated the effectiveness of adding ASOFA + SCR to MRYS #1. We suggest that ASOFSA + SCR can achieve 0.05 lb/mmBtu.

Response: See response to Comment 8. The Department used 90% for ASOFA + SNCR.

Comment 51: NDDAQ overestimated the costs associated with adding SCR. In the absence of supporting documentation by NDDAQ, we also estimated a total annual cost for ASOFA + SCR with reheat at $9.7 million and $1,028 per ton.

Response: Minnkota has provided its own estimate of the cost of SCR as part of the BACT process under their Consent Decree. Minnkota's estimate has been included in the BART determination.

Comment 52: We believe that ASOFA + SCR with reheat represents BART for MRYS #1.

Response: Based on the Department's evaluation of the five statutory factors, we believe SCR + ASOFA is not BART. As explained in the Department's analysis, the cost effectiveness is excessive, the incremental cost over the next most efficient control option (ASOFA + SNCR) is excessive and there is very little visibility improvement especially when the Department's cumulative visibility modeling is considered (0.01 deciviews average in the 20% worst days). The cumulative modeling results represents the most realistic degree of improvement in visibility which may reasonably be anticipated to result from the use of such technology.

M.R. Young Station Unit 2

Comment 53: NDDAQ is proposing upgrading the existing wet scrubber to limit SO_2 emissions to 0.15 lb/mmBtu **or** 95% reduction on a 30-day rolling average basis. We have estimated that the proposed scrubber upgrade will result in an approximately 1.2 dv improvement in visibility at Theodore Roosevelt NP and 2.2 dv cumulatively when Lostwood WA is included. We commend NDDAQ for the proposed new wet scrubbers, but recommend that the limits require **both** 95% control **and** 0.15 lb/mmBtu, as well as specific caps on emissions.

Response: See response to Comment 13.

Comment 54: NDDAQ proposes that NO_x emissions be limited to 3,995.6 lb/hr on a 24-hour rolling average basis during startup. We recommend that NDDAQ limit the mass emission rate (e.g., lb/hr) to the rate under normal operation.

Response: See response to Comment 49.

Comment 55: NDDAQ underestimated the effectiveness of adding ASOFA + SCR to MRYS #2. We suggest that ASOFSA + SCR can achieve 0.05 lb/mmBtu.

Response: See response to Comment 8.

Comment 56: NDDAQ overestimated the costs associated with adding SCR. In the absence of supporting documentation by NDDAQ, we estimated total annual costs for ASOFA+tail-end SCR with reheat at $15.6 million and $898 per ton.

Response: Minnkota has provided a much more detailed cost estimate of SCR with reheat as part of their BACT process under their Consent Decree. This estimate has been used in the Department's BART determination.

Comment 57: We believe that ASOFA + SCR with reheat represents BART for MRYS #2.

Response: Based on the Department's analysis of BART for MRYS Unit 2, we believe the cost effectiveness of ASOFA + SCR is excessive, the incremental cost over the next most efficient option (ASOFA + SNCR) is excessive and the visibility improvement is very small going from ASOFA + SNCR to ASOFA + SCR (see Department's final analysis). Therefore, we believe ASOFA + SCR is not BART.

Modeling

Comment 58: NDDAQ indicates that the purpose of the hybrid modeling is as weight of evidence to discount the impact of international (particularly Canadian) emissions and to better represent plume dispersion from point sources, particularly those closer to the Class I areas. While the CMAQ 36 km grid resolution does allow dilution of the plumes from point sources, ND's hybrid modeling assumptions raise more questions that are answered. CALPUFF does allow tracking of individual plumes but the model chemistry is much simplified compared to CMAQ and the methods required to normalize CMAQ results to CMAQ-CALPUFF hybrid results becomes quite elaborate and questionable.

Response: To address commenter's concerns, Sections 8.5.6 ("Normalizing Hybrid Model RRF to WRAP CMAQ RRF") and 8.6 ("The Impact of International Sources on North Dakota Class I Areas") of the draft SIP have been combined and extensively rewritten in a new Section 8.5.6. The purpose of this revision is to clarify the usage and purpose of the NDDoH hybrid modeling system. The emphasis of the rewrite is that the hybrid model was used only to adjust WRAP CMAQ results, and not as a "stand alone" system. We believe the new language helps to clarify the intent and legitimacy of the NDDoH hybrid modeling approach. The NDDoH also notes that values used for background ammonia and other input settings for CALMET-CALPUFF (including "alternative protocol" settings of ongoing concern to EPA and FLMs) become less critical as the effect of values used both in the numerator and denominator to a significant extent "cancel out" in the adjustment ratio applied to WRAP CMAQ results. Certainly, these settings will have less impact than if the hybrid model was used in a "stand alone" sense.

We raise the following technical issues with the CALPUFF application:

A) Ammonia is known to be an important input to determine the amount of ammonium nitrate (NH_4NO_3) formed in CALPUFF. Regional ambient concentrations of ammonia are poorly understood. ND has one ammonia monitor at Beulah; please describe the type of monitor and the land use at Beulah compared to other areas of the CALPUFF domain. We question if this monitor is representative of the CALPUFF domain. We note that monthly average NH3 from 2001-2002 was used as background ammonia in CALPUFF after removing days influenced by a source region. The draft Plan should identify that source region.

Response: The ammonia monitor at Beulah is a Thermo Scientific 17c continuous sampler, based on the chemiluminescence analytical process. Land use in the vicinity of the Beulah monitoring site is predominantly rangeland and cropland, which is typical for most of North Dakota. Land use in the State is relatively homogenous, with cropland slightly more common than rangeland in eastern and northern parts of the State, and rangeland slightly more common than cropland in the southwest part of the State. As such, the Beulah ammonia monitor should be representative of the Calpuff domain. When processing Beulah monthly background ammonia values to use with CALPUFF, hourly observations associated with the northwest wind-direction quadrant were filtered from the 2001-2002 data set. This was done to avoid bias due to the Great Plans Synfuels plant located about eight kilometers northwest of the monitor site. This plant produces significant amounts of ammonia as a result of its production process.

B) EPA disapproved the use of the Ammonia Limiting Method to define NH3 levels in the VISTAS application cited by NDDAQ.

Response: The NDDoH did not use the Ammonia Limiting Method (ALM) to define ammonia levels. Background ammonia for NDDoH hybrid modeling was based on actual ambient ammonia monitoring data. The NDDoH used the ALM simply to avoid double-counting of ammonia by multiple puffs in the modeling domain.

C) For POSTUTIL, hourly ammonia data for 2001 -2003 were used and the Plan does not mention removing data. The Plan should identify if different years were used for the two applications. It appears that the ammonia levels at Lostwood were doubled compared to measured values based on the expectation that Lostwood is closer to ammonia sources in Canada. However, that adds a subjective adjustment to the CALPUFF modeling that brings into question the presumption that CALPUFF modeling is more accurate than just using CMAQ at 36 km.

Response: Based on consultation with Joe Scire (TRC Atmospheric Studies Group), the NDDoH elected to use hourly background ammonia data (Beulah monitor) with POSTUTIL. Use of the hourly data (rather than monthly) tended to improve hybrid model agreement with sulfate and nitrate observations in the performance evaluation. As was the case in the ammonia data set used with CALPUFF, hourly data associated with the northwest wind direction quadrant were removed from the data set used with

POSTUTIL, because of bias due to a large ammonia source (Great Plains Synfuels Plant) located northwest of the Beulah monitor site. Due to resultant missing data periods, the three year period 2001-2003 of hourly ammonia data was averaged to prepare a composite hourly data set for 2002. The NDDoH considers this a refinement of the monthly data used with CALPUFF, and notes that ammonia background used with POSTUTIL completely supersedes the ammonia background used in CALPUFF (this conclusion is the result of extensive testing).

Regarding adjustment of Beulah monitoring data for the Lostwood location, the assumption of higher ammonia background at Lostwood is consistent with predominant land use and other anecdotal evidence (see Section 8.5.4), and it provided better agreement with observations in hybrid model performance evaluations for sulfate and nitrate. We note again that NDDoH hybrid modeling is not as sensitive to the specific ammonia background applied because of the ratio approach used to adjust WRAP CMAQ results (see response to Comment 58).

D) We note that four ozone monitors in central ND were selected to represent background ozone in CALPUFF. Are there only four ozone monitors in the CALPUFF domain? Table 8.6 says background value for ozone was 30 ppb, but does not link this to monitoring data.

Response: The four ozone monitors used to represent background ozone in the hybrid model (CALPUFF) are located near the primary transport path between larger North Dakota point sources and Class I areas. Though the NDDoH operates additional ozone monitors in the State, ozone observations are relatively homogeneous across North Dakota with little spatial variability. It is not likely that the inclusion of data from additional ozone monitors would have provided any meaningful difference in results. The NDDoH used hourly ozone data from the four monitors for year 2002 with CALPUFF. The 30 ppb background ozone number in Table 8.6 represents a typical annual average monitored value, and applied only in those rare cases when the hourly value was missing.

Comment 59: We question the Hybrid model performance evaluation. Model performance evaluations are usually based on raw model output. We understand that the Hybrid model results were normalized before evaluation and then were normalized again to the WRAP baseline results. The need to normalize the CALPUFF relative response factors to the WRAP results, brings into question the value of using the CALPUFF hybrid regional model to discern the benefits of NDDAQ strategies.

Response: The performance evaluation was based on raw model output from the hybrid system. Model output was not normalized or adjusted in any way prior to comparing with observations. Language has been added to Section 8.6 to clarify this point.

Comment 60: Section 8.6, including Figure 8.10, describes a possible way to account for international emissions when assessing the progress toward the goal of natural conditions. While we agree that examining the contribution to extinction for each aerosol species is a good approach to understanding if a State is meeting its fair share of emissions reductions associated with visibility impacts at a Class I area, the method described in this section and in the figure raise concerns since there was no assessment of the international component of the natural condition estimate. The value in 2064 illustrated in Figure 8.10 uses the same natural condition endpoint for the total extinction as well as the "U.S. Source" extinction, yet the 2064 natural condition estimates for aerosol species include some global or international component. We believe that a better way to address reasonable progress by extinction component is to assess the reduction needed for each aerosol species measured in the baseline period to the end of the first planning period and then assess if a state's plan achieves a comparable reduction for its share of extinction at the Class I areas.

Response: In its approach for discounting the impact of Canadian source visibility-affecting emissions, the NDDoH modified the emissions inventories used in the adjustment of WRAP CMAQ modeling results (see revised Section 8.5.6). The modification involved elimination of all Canadian sources, except for the Canadian component of natural background, which was retained through adjustment of boundary conditions in CALPUFF. Therefore, the modified emissions inventories accounted for all non-Canadian sources, including all components of natural background. Thus, there was no need to adjust the end point for the "U.S. sources" glide path. For clarification, however, further description regarding the context of "U.S. sources" has been added to Section 8.6, and labels for "U.S. sources" glide paths in Figures 8.10, 8.24, 8.26 and 8.27 have been changed to "Canadian Sources Discounted Glide Path".

Reasonable Progress Goals

Comment 61: The State should rely on WRAP regional modeling as the primary tool for demonstrating progress toward visibility improvement goals. The CMAQ-CALPUFF hybrid modeling is problematic in several ways and gains ND little benefits compared to using WRAP products. Two WRAP products that were omitted but should be included to help ND in making its reasonable progress determination are 1) Weighted Emissions Potential (WEP) and 2) extinction glide paths for SO_4, NO_3, and OC.

The uniform rate of progress glide path cannot be revised to account for contributions from natural sources or international sources under current or 2018 conditions without also removing these contributions from the 2064 endpoint. While the contribution from natural and international sources by 2064 is unknown, it may be comparable to current contributions. Therefore removing the estimated contributions from current conditions without also accounting for those contributions to the 2064 endpoint inappropriately changes the slope of the uniform rate of progress

It would be more appropriate to use the WRAP CAMx-PSAT results to demonstrate the relative contributions to sulfate and nitrate from Canadian and ND emissions at the North Dakota Class I areas. The Plan has already included these results in Table 6.7.

We suggest NDDAQ use the WRAP extinction glide paths to show the improvement in SO_4 or NO_3 due to emissions reductions from all sources in the WRAP 2018 inventory, and compare the ND emissions reductions by 2018 to emissions reductions from Canada and neighboring states.

It would be informative for the Plan to include what percent of the State's total SO_2 and NO_X emissions from point sources is being reduced under BART. What other point source or area source reductions are reasonable?

Response: The usage and purpose of the NDDoH hybrid modeling system was clarified in the response to Comment 58, and in the revision of Section 8.5.6 of the SIP. The NDDoH does not agree that the NDDoH modeling provides little benefit compared to using WRAP products. Through use of the hybrid model to adjust WRAP CMAQ results, the NDDoH was able to produce a suite of analyses related to weight of evidence, none of which were available in the original WRAP products. The NDDoH regards these weight of evidence analyses more useful than the additional WRAP products suggested by the commenter.

Regarding the uniform rate of progress glide path 2064 endpoint, see response to Comment 60.

The SIP already includes the WRAP Cam_x-PSAT results, demonstrating the relative contributions to sulfate and nitrate from Canadian and ND emissions at North Dakota Class I areas, in Table 6.7 and 9.12.

A comparison of North Dakota emissions reductions by 2018 with emission reductions from Canada and neighboring states has been added to Section 9.

The Department has reviewed other point sources, agricultural tillage operations, smoke management techniques and oil and gas operations for possible air pollution control requirements. The Department determined that additional controls were not reasonable during this planning period. However, all sources of emissions will be reevaluated during future planning periods.

Comment 62: For stationary sources, NDDAQ developed a methodology to look at options for controls for sources, beyond the source subject to BART, contributing to the major components of aerosol extinction on the worst 20 percent days. While we generally agree with the use of emissions over distance (Q/d) as a screening tool, we note that the Heskett facility was not included in Table 9.4 even though NDDAQ proposes to exclude the source from BART requirements.

Response: The status of Heskett Unit 2 is being reevaluated and will be addressed in a supplement to this SIP revision.

Comment 63: Table 9.9 summarizes the results of assessing the costs and visibility improvement associated with possible controls on these facilities. The two power generation facilities, Coyote and AVS, have emissions and Q/d impacts that are similar, if not greater than, BART sources that will be required to add controls. The methodology to calculate visibility improvements noted in Table 9.9 are not explained in this section but appear to be some calculation of changes in the long-term metric of the 20 percent worst visibility days. These sources likely contribute to higher impacts on a daily basis, and a reduction in their emissions would be part of a broad strategy to reach natural conditions at the Class I areas. As such

NDDAQ should examine the total improvement from the suite of sources as part of its reasonable progress assessment, not a simple unit by unit approach.

Response: The improvement in the 20% worst days was used to indicate the amount of visibility improvement. The SIP was revised to better explain this. Addressing individual days under reasonable progress is inconsistent with the reasonable progress goals in 40 CFR 51.308(d)(1) which states "The reasonable progress goals must provide for improvement in visibility for the most impaired days over the period of the implementation plan and ensure no degradation in visibility for the least impaired days over the same period." 40 CFR 51.301 defines the most impaired days as meaning "the average visibility impairment (measured in deciviews) for the 20% of monitored days in a calendar year with the highest amount of visibility impairment." 40 CFR 51.301 defines the least impaired days as the average visibility impairment (measured in deciviews) for the 20% of monitored days in a calendar year with the lowest amount of visibility impairment." It is clear that reasonable progress goals should be established based on the average of the "most impaired days" and the "least impaired day", not individual days.

The Department did evaluate the cumulative effects of the most efficient remaining options. As stated on p. 182, the cumulative visibility improvement was 0.11 deciviews at LWA and 0.03 deciviews at TRNP. The less efficient control options would provide even less improvement.

Comment 64: The assessment of non-air quality impacts on page 181 in the draft SIP does not address the substantial human health benefits associated with reductions in fine particulate concentrations resulting from additional control of SO_2 and NO_X emissions from Coyote and AVS since they would become the newest and highest emitters of these pollutants after implementation the SIP as drafted.

Response: Reasonable progress is evaluated based on four stationary factors 1) the cost of compliance, 2) the time necessary for compliance, 3) the energy and nonair quality environmental impacts of compliance, and 4) the remaining useful life of the source.

The Energy and Non-Air Quality Environmental Impacts Analysis does not address health effects from air emissions. As stated in the BART guideline "In the non-air quality related environmental impacts portion of the BART analysis, you address impacts **other than air quality** [emphasis added] due to emissions of the pollutant in question. Such environmental impacts include solid or hazardous waste generation and discharges of polluted water from a control device."

Even though health effects are not evaluated under this section of the BART analysis, the Department reviewed ambient monitoring data in the vicinity of Antelope Valley Station and Coyote Station. Five ambient monitors are operated in the immediate area. In 2008, the maximum 3-hour SO_2 concentration was 39 ppb (7.8% of the NAAQS), the maximum 24-hour SO_2 concentration was 9 ppb (6.4% of the NAAQS) and the maximum annual average was 1.8 ppb (6% of the NAAQS). For NO_2, the maximum annual average was 2.7 ppb (5.1% of the NAAQS). Given the low concentration of these pollutants, any benefits to health from additional controls and these facilities would be extremely hard to quantify.

Comment 65: The decision on additional point source controls would be better informed by analysis of the how the emissions from sources within the State contribute to nitrate and sulfate concentrations in Class I areas, both inside and outside of the State, in the baseline period compared with the model projections in 2018. If BART controls on stationary sources as well as expected reductions from Federal mobile source, small engine, and fuel requirements would achieve a reduction that, had all other contributing States and other regions met similarly, would put the total aerosol extinction on the uniform rate of progress path, then the State could better support a limited approach to additional controls in this first planning period. However, based on our review of the information supplied in the draft Plan and its appendices, we believe there are cost-effective controls for the Coyote and AVS facilities that should be implemented under the reasonable progress provisions.

Response: The Department reviewed these sources based on the four statutory factors. We looked at the visibility improvement using an emissions inventory that included all contributing sources (cumulative analysis). This analysis showed very little improvement if additional air pollution controls (SO_2 and NO_x controls) are installed. We believe an individual analysis for SO_4 and nitrate will show the same result.

Although the Department found (using the four statutory factors) that additional controls are not reasonable, Otter Tail Power Company has committed to reduce NO_x emissions at the Coyote Station by approximately 35%. This requirement will be included as part of this SIP revision. In addition, all sources will be reevaluated during the next planning period.

Long-Term Strategy

Comment 66: On Page 184, there is discussion of the reduction in sulfur dioxide emissions from the R.M. Heskett Station No. 2. As noted earlier, we believe this facility is subject to BART and should be assessed under the BART provisions. In addition, the reduction in emissions reflect a 21 percent reduction from current emissions. The 70 percent coal-to-stack removal cited in the draft Plan implies a greater reduction from current emissions.

Response: The status of Heskett 2 is being reevaluated and will be addressed in a supplement to this SIP revision.

Comment 67: We request that NDDAQ include in the Long-Term Strategy a linkage between the prevention of significant deterioration program and its assessment of visibility impacts and the Regional Haze Plan in the SIP. This will ensure that new sources are reviewed in a manner that does not jeopardize the reasonable progress goals established by this Plan.

Response: As part of the PSD program, the Department will evaluate the cumulative effect of all sources on the 20% worst and 20% cleanest days to ensure there is no degradation from baseline conditions. This has been added to the Long-Term Strategy as Paragraph 10.7.

TO: Participants in the Northern Class I Areas Consultation Process

RE: Northern Class I Areas Consultation Conclusion

As you are aware, Minnesota is home to two federal Class I areas, Voyageurs National Park (VNP) and the Boundary Waters Canoe Area Wilderness (BWCAW), located in the northern portion of the state. Under the federal Regional Haze Rule (40 CFR 51.300-309), the State of Minnesota is required to work to improve visibility in these two areas, with a goal of no man-made visibility impairment by 2064.

Under the portion of the Regional Haze regulations at 40 CFR 51.308(d)(1)(iv), states with Class I areas are required to develop reasonable progress goals (RPG) for visibility improvement at their Class I areas and associated measures to meet those goals, in consultation with any other State or Tribe that may reasonably cause or contribute to visibility impairment in those areas. This letter provides information on how Minnesota intends to address the reasonable progress goals, identification of the states that cause or contribute to visibility impairment in Minnesota's Class I areas, and our expectations for continued coordination with those states on haze-reducing strategies.

Beginning in 2004 and 2005, a number of discussions were held between state and tribal representatives in the upper Midwest concerning air quality planning to address regional haze in the four Class I areas in Michigan and Minnesota. Formal discussions geared toward the State Implementation Plans (SIP) consultation requirements began in July 2006, in a conference call among representatives from Iowa, Michigan, Minnesota, North Dakota, Wisconsin, the Mille Lacs and Leech Lake bands of Ojibwe, and Federal Land Managers (FLM), Regional Planning Organization (RPO) and U.S. Environmental Protection Agency (EPA) personnel. It was decided that other potentially contributing states should be asked to participate in the consultation process, and that consultation should continue through ongoing conference calls during the development of the regional haze SIP. Minutes of the conference calls and other documentation can be found on the Lake Michigan Air Directors Consortium/Midwest Regional Planning Organization (LADCO/MRPO) Web site.[1]

The group consulted on technical information, producing a document entitled *Regional Haze in the Upper Midwest: Summary of Technical Information*, which lays out the basic sources that cause and contribute to haze in the four Northern Class I areas, as agreed to by all the participating states.[2]

---

[1] http://www.ladco.org/Regional_haze_consultation.htm
[2] http://www.ladco.org/Final%20Technical%20Memo%20-%20Version%205d1.pdf

Based on the technical information contained in this document and other supporting analyses, Minnesota has determined that, in addition to Minnesota, Illinois, Iowa, Missouri, North Dakota, and Wisconsin are significant contributors to visibility impairment in VNP and the BWCAW. Attachment 1 to this letter provides a summary of how Minnesota reached this conclusion.[3]

The Minnesota Pollution Control Agency (MPCA) has not yet completed modeling to determine the RPG for these two Class I Areas. However, because of the varying timelines and different non-attainment issues impacting Minnesota and other contributing states, Minnesota intends to submit a RPG resulting from implementation of the minimum interim control measures Minnesota would consider to be reasonable. This decision reflects the need for more in-depth analysis before additional control measures can be determined to be reasonable. The RPG would be revised in the Five Year SIP Assessment to reflect final control measures.

In addition to on-the-books controls, such as the Clean Air Interstate Rule (CAIR), Minnesota expects the RPG to reflect Best Available Retrofit Technology (BART) determinations in Minnesota and surrounding states (where known), the plan for a 30 percent reduction in combined sulfur dioxide (SO_2) and nitrogen oxides (NO_X) emissions in Northeastern Minnesota, voluntary emission reductions planned by Minnesota utilities beyond those predicted from CAIR, and, where known, any additional control measures undertaken in other states for regional haze or attainment purposes. The MPCA expects that the modeling information needed to set the RPG would be available by October 2007.

Minnesota commits to evaluating additional control measures and implementing those that are reasonable under the four factors listed in 40 CFR 51.308(d)(1)(i)(A) in the 2008 SIP. Minnesota expects that additional control measures may be found to be reasonable, and commits to including a plan for implementation of those additional reasonable measures in the Five Year SIP Assessment. Minnesota asks the five other significantly contributing states to make these same commitments for further evaluation and implementation of reasonable control measures.

In particular, Minnesota asks Iowa, Missouri, North Dakota, and Wisconsin to evaluate further reductions of SO_2 from electric generating units (EGU) in order to reduce SO_2 emissions by 2018 to a rate that is more comparable to the rate projected in 2018 for Minnesota, approximately 0.25 lbs/mmBtu. Minnesota believes that Illinois is already in the process of meeting this goal. Emission reductions in Wisconsin are particularly important, as Wisconsin is the highest contributor outside Minnesota to visibility impairment in Minnesota's Class I areas.

Minnesota also asks North Dakota to evaluate the potential for reductions of NO_X from EGUs due to predicted higher NO_X emission rates compared with Minnesota and other contributing states. Illinois, Missouri, and Wisconsin are in the process of evaluating NO_X emission

---

[3] Minnesota is relying primarily on data analysis and technical work done by MRPO and CENRAP.

reductions for their ozone SIPs. Minnesota would expect these three states to share information on the NO_X controls being undertaken as part of those ozone SIPs.

Minnesota acknowledges that each state is in a unique position; for example, North Dakota has a different regulatory background and a different fuel mix than other contributing states. Minnesota's use of emission rates to point towards areas where additional emission control strategies should be investigated does not mean that Minnesota expects all the contributing states to achieve the same emission rates. However, the contributing states with higher emission rates should evaluate potential control measures, and should, in their initial SIPs or Five Year SIP Assessments, show either enforceable plans to reduce emissions or a rationale for why such emission reductions are not reasonable (e.g., an overly high cost in $/ton or $/deciview, or lack of visibility improvement).

Minnesota, in turn, also commits to a more detailed review of potential emission reductions from large Industrial, Commercial, and Institutional (ICI) Boilers and other point sources (such as reciprocating engines and turbines) with regulations or permit limits developed by 2013 and included in the Five Year SIP Assessment if control measures on these source categories appear to be reasonable. Minnesota asks the five contributing states to make a similar commitment.

It is the intent of Minnesota to proceed with the development and submittal of a Regional Haze Plan which includes the aforementioned RPG and expectations for contributing states. Minnesota commits to continuing work with the other states to review and analyze potential region-wide control strategies and emission reductions plans and to continue on-going assessments of progress towards visibility improvement goals.

Minnesota asks that any additional control measures found to be reasonable will be included in each state's SIP or Five Year SIP Assessment in an enforceable form. This will ensure that the control measures are on track to be implemented by the 2018 deadline for submittal of SIPs covering the second phase of the Regional Haze process.

Minnesota believes that the consultations conducted to date satisfy the consultation process requirements, providing for consistency between state SIPs and allowing each state to move forward with SIP preparation and submittal. As necessary, Minnesota will engage in future consultation to address any issues identified in the review of the Regional Haze SIPs, any additional technical information, and to ensure continued coordinated efforts among the Midwestern states.

Attached to this letter is an outline of the reasonable progress discussion to appear in our SIP and additional supporting tables and graphs.

In order to document the consultation process, the MPCA is asking that the State and Tribal recipients of this letter respond within 30 days with a letter documenting that these consultations have taken place to the satisfaction of your State or Tribe, or detailing areas where additional consultation should occur. Those states that Minnesota has identified as additional contributing states should respond with your agreement or disagreement with the determination of contributing states and the additional controls strategies that will be evaluated.

Thank you for your participation and contributions in this consultation process. Your time and efforts are appreciated. If you require additional information regarding this matter, please contact John Seltz at 651-296-7801 or john.seltz@pca.state.mn.us.

Sincerely,

Brad Moore
Commissioner

Attachment 1: Supporting Technical Information – Determination of Contributing States

Minnesota used the LADCO 2002 – 2003 Trajectory Analyses and the LADCO 2018 PSAT analysis, using a 5% threshold of contribution from either analysis to either of Minnesota's Class I areas, to define a contributing state. Based on this information, the States identified as contributing to visibility impairment in Minnesota's Class I Areas are: Minnesota, Wisconsin, Illinois, Iowa, Missouri, and North Dakota.

The table below documents the percent contribution to visibility impairment by the States that have participated in the Northern Class I consultation process, estimated from 2000 – 2003 LADCO trajectory analysis, with supporting information from the CENRAP 2002 PSAT model of the 20% worst days.[4]

State Impacts on Minnesota's Class I Areas – Baseline Period

	LADCO Trajectory Analyses (2000-2003)		CENRAP PSAT Modeling (2002)	
	BWCAW	VNP	BWCAW	VNP
Michigan	0.7%	1.6%	2.6%	1.4%
Minnesota	37.6%	36.9%	25.4%	27.6
Wisconsin	11.1%	9.7%	8.6%	5.6%
Illinois	2.7%	1.2%	7.3%	3.7%
Indiana	1.2%		3.8%	1.8%
Iowa	7.4%	10.2%	3.9%	3.8%
Missouri	3.3%	0.3%	2.7%	2.1%
N. Dakota	5.9%	7.1%	4.8%	7.1%
TOTAL	69.9%	67.0%	59.2%	53.1%

The following table documents the percent contribution from these same states projected for the future based on LADCO's 2018 Particulate Matter Source Apportionment Technology (PSAT) analysis, with supporting information from the CENRAP 2018 PSAT model of the 20% worst days.[5] Although in some cases the percentage impacts predicted by CENRAP are lower than those predicted by the MRPO PSAT analysis (Iowa, Missouri), the identified states remain the higher contributors. The relative order of contributing states does not change much between 2002 and 2018.

---

[4] Environ. (2007, July 18). *CENRAP PSAT Visualization Tool.* (Corrected Version). Available on the CENRAP Projects webpage

[5] Ibid.

State Impacts on Minnesota's Class I Areas – Future Year (2018 PSAT)

	LADCO PSAT Modeling (2018)		CENRAP PSAT Modeling (2018)	
	BWCAW	VNP	BWCAW	VNP
Michigan	2.6%	1.3%	2.2%	1%
Minnesota	30.5%	35.0%	19.8%	18.0%
Wisconsin	10.4%	6.3%	6.0%	3.1%
Illinois	5.2%	3.0%	3.7%	1.6%
Indiana	2.9%	1.6%	1.8%	0.8%
Iowa	7.6%	7.4%	2.9%	2.5%
Missouri	5.2%	4.3%	2.3%	1.6%
N. Dakota	5.7%	10.3%	3.7%	4.7%
TOTAL	70.1%	69.2%	42.5%	33.3%

The states with contributions over 5% to the Class I areas in these analyses generally match well with the impacting states shown in the Area of Influence (AOI) analysis done by Alpine Geophysics for CENRAP.

AOIs for Minnesota's Class I Areas[6]

Attachment 2: Outline of an Approach to Defining Reasonable Progress for Minnesota Class I Areas in the Minnesota Regional Haze SIP

Under EPA rules, Minnesota has a responsibility to set a Reasonable Progress Goal (RPG) for visibility in the Boundary Waters and Voyageurs Park. Because the states that contribute to our Class I areas will submit their SIPs at different times, Minnesota sets forth the following proposal for setting a RPG for our two Class I areas. This document lays out the elements that we plan to include.

Minnesota's Long Term Strategy section will include those control strategies which we plan to undertake and which we consider to be reasonable. It will also include any known controls that are being undertaken in the nearby states, particularly the five states (IL, WI, ND, IA, and MO) that have been identified as contributors to BWCAW and VNP.

- Minnesota's LTS Contains
  - BART
    - For Minnesota: Minimal emission reductions
    - As known for other states
  - CAIR and resulting EGU reductions
    - For Minnesota
    - As known for other states
  - Control strategies for $PM_{2.5}$ and Ozone attainment SIPs
    - As known for other states
  - Other federal on-the-books (OTB) controls:
    - Tier II for on-highway mobile sources
    - Heavy-duty diesel (2007) engine standards
    - Low sulfur fuel standards
    - Federal control programs for nonroad mobile sources
  - Additional Emission Limitations
    - NE Minnesota Plan (30% reduction in combined SO_2/NO_X as a fair share)
    - Additional voluntary reductions as a result of MN Statutes 216B.1692 (emission reduction rider)
    - Anything known for other states
  - Other long term strategy (LTS) Components (without specific emission reductions)
    - Measures to mitigate emissions from construction
    - Source retirement and replacement
    - Smoke management for prescribed burns in Minnesota

After documenting all the components of the LTS, Minnesota will lay out the RPG determined for the best and worst days at VNP and BWCAW.

Reasonable Progress Goals

Once determined, the RPG submitted in Minnesota's SIP will represent an **interim**, **minimum** visibility improvement Minnesota would consider to be reasonable, and contain emission reductions resulting from the elements of the long term strategy.

At this time, Minnesota believes that this is an appropriate goal because other impacting states are working on a multi-SIP approach and have yet to determine what reductions are reasonable in their states for both haze and attainment purposes. Although we cannot compel the states to undertake reductions, Minnesota would expect further emissions reductions than are documented here, resulting in larger visibility improvement. Minnesota intends to revise the RPG for 2018 in the Five Year SIP Assessment, in order to reflect the additional control strategies found to be reasonable.

Steps in Reviewing Control Strategies and Revising RPG

In reviewing additional control strategies to determine those that are reasonable under the Regional Haze rule, Minnesota will focus on strategies that will result in emission reductions in those states that are significant contributors to visibility impairment in either BWCAW or VNP: Minnesota, Wisconsin, Iowa, N. Dakota, Missouri and Illinois.

The MPCA commits to further evaluation of reasonable control strategies that are possible within Minnesota. Minnesota will work with the other contributing states through their submittals of the first haze SIP and through 2013 to develop reasonable control strategies.

In the Five Year SIP Assessment, the MPCA would submit enforceable documents for any additional control measures found to be reasonable within Minnesota. In addition, that report would contain a listing of the additional control measures to be implemented by the other contributing states. Minnesota would then submit modeling that includes all these enforceable measures and would revise the 2018 RPG to reflect the larger degree of visibility improvement expected from the chosen control strategies.

Specific Control Strategies to Be Reviewed

Minnesota will use the EC/R five factor analysis report, the control cost analysis carried out by Alpine Geophysics for CENRAP and the CENRAP Control Sensitivity Model run to identify reasonable region-wide emission reduction strategies. (*See Attachment 3*).

The specific strategies that at this time appear to potentially be reasonable, and Minnesota's expectation for each of these strategies for other states, are outlined below.

EGU SO_2 Reductions

Minnesota will ask the contributing states to look at their EGU emissions of SO_2; Minnesota will particularly focus on possible reductions in states with emission rates that appear to be higher than the average among the Midwestern states. Since contributor states face a variety of regulatory demands and fuel types, it may not be possible to attain uniform emission performance. An emission rate of about 0.25 lb/mmBTU should be achievable in a cost-effective manner; this is the level being achieved in Minnesota and Illinois, and the EC/R report shows that the "EGU1" scenario, a 0.15 lb/mmBTU emission rate, is generally achievable in the Midwest at a reasonable $/ton figure. (See Attachment 3).

Minnesota asks the identified states to demonstrate that reductions are occurring or being undertaken that will allow the state to reach at least the 0.25 lb/mmBTU emission rate, or to describe in their SIPs or Five-Year SIP Assessments why further reductions of SO_2 from EGU are not reasonable. Further reductions may not be reasonable due to the cost of implementation in $/ton or $/deciview or lack of impact on visibility impairment, but they should be evaluated.

At present, it appears as though Illinois has planned or proposed reductions that appear reasonable. It appears that more cost effective reductions are possible in Iowa, Missouri, North Dakota, and Wisconsin. Since Wisconsin is the largest non-Minnesota contributor to Minnesota's Class I areas, their efforts to reduce EGU SO_2 emissions are particularly important.

EGU NO_X Reductions

Wisconsin, Missouri, and Illinois have already reduced NO_X emissions to alleviate ozone standard violations, and Iowa appears to already have relatively low EGU NO_X emissions.

Minnesota will ask North Dakota to look at their EGU emissions of NO_X and to describe in their SIP or Five-Year SIP Assessment why further reductions of NO_X from EGU are not reasonable. Again, an emission rate of approximately 0.25 lb/mmBTU appears to be a reasonable benchmark. Further reductions may not be reasonable due to the cost of implementation in $/ton or $/deciview or lack of impact on visibility impairment, but they should be evaluated.

ICI Boiler Emission Reductions

Minnesota will commit to a more detailed review of potential NO_X and SO_2 reductions from large ICI boilers. Regulations or permit limits will be developed by 2013 if significant cost effective reductions prove feasible from this sector. Minnesota will expect the five contributing states to make at least this level of commitment.

Other Point Source Emission Reductions

Reciprocating engines and turbines appear to be a sector with potential cost effective NO_X controls. Minnesota commits to review this sector in more detail and if, after consideration of planned federal control programs, cost effective reductions appear feasible, Minnesota commits to develop regulations or permit limits for major sources by 2013. Minnesota will expect the five contributing states to make a similar commitment.

Mobile Source Emission Reductions

There appear to be relatively few cost effective NO_X controls for transportation available to states. Minnesota commits to work with LADCO states to implement appropriate cost effective NO_X controls to improve visibility and lower ozone levels in non-attainment areas.

NO_X Modeling, Ammonia, Agricultural Sources

It is not appropriate to commit to control of ammonia sources at this time. However, there is a clear need to improve 1) our understanding of the role of ammonia in haze formation, 2) our understanding of potential ammonia controls, and 3) the accuracy of particulate nitrate predictions. Minnesota does not consider it our responsibility to conduct such research. Minnesota therefore encourages EPA and the regional planning organizations to continue work in these areas and commits to work with EPA and the RPOs to these ends.

Timeline for Reviewing Control Strategies

Minnesota commits to reviewing these control strategies on such a timeline that the 2013 SIP Report will include the four factor analysis for these control strategies, and that any control strategies deemed to be reasonable will be in place with an enforceable document (state rule, order, or permit conditions). Although any control measures ultimately deemed to be reasonable may not be fully implemented by 2013, they will be clearly "on the way" and the SIP Report will include estimates of emission reductions and projected 2018 visibility conditions.

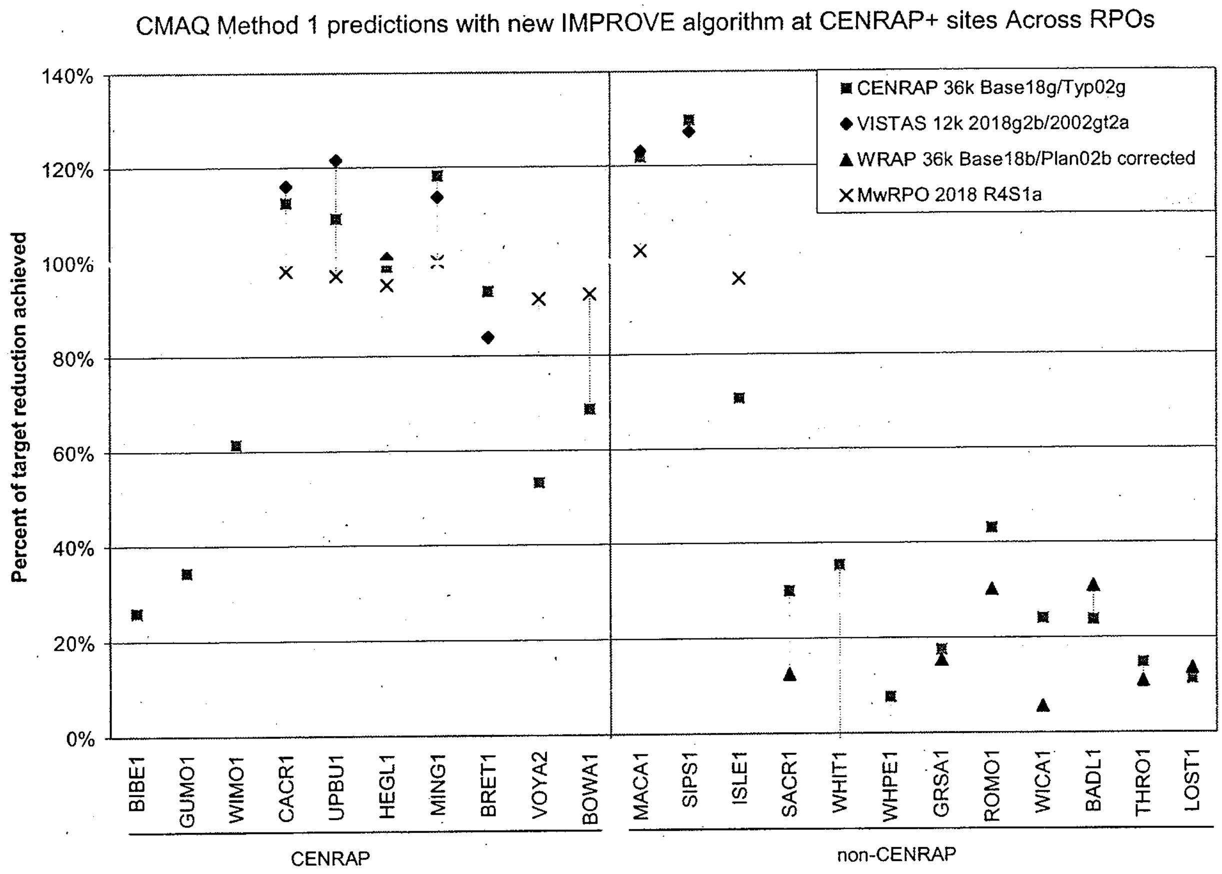
Acknowledging that most states are far along in the process of writing their Regional Haze SIPs, Minnesota would expect that all other contributing states would commit to a timeline that would allow reasonable predictions of the emission reductions and visibility improvement by 2018 from those states in the 2013 SIP Report.

Attachment 3: Supporting Technical Information – Need for Additional Control Strategies

Although there are some fairly major differences in the degree of visibility improvement expected at VNP and BWCAW due to on- the- books controls, projections by both CENRAP and Midwest RPO show that Minnesota's Class I areas are not yet projected to meet the Uniform Rate of Progress, as shown in the graph below.[7] In this graph, the URP is the "target reduction."

EPA's recent guidance on determining the reasonable progress goal (RPG) indicates that states may set a RPG that provides for more, less, or equivalent improvement as the URP. However, the guidance continues to emphasize that an analysis of control strategies with the four factors is necessary; Minnesota believes this is particularly true in light of the lesser degree of visibility improvement shown from on- the- books controls in Minnesota's Class I Areas.

The EGU 2018 Summary table, following, shows projected 2018 EGU SO2 and NOX emissions. Highlighted cells indicate specific states and pollutants of concerns, where Minnesota has requested evaluation of potential reasonable control measures.[8]



CMAQ Method 1 predictions with new IMPROVE algorithm at CENRAP+ sites Across RPOs

Minnesota also used the cost-curve analysis performed for CENRAP by Alpine Geophysics, originally included in the *CENRAP Regional Haze Control Strategy Analysis Plan* and updated in March 2007, to determine which states might have additional reasonable control strategies. The cost curves were used to perform a modeling run (the "Control Sensitivity Run") in order to determine the visibility improvement that could result from implementing certain control strategies.[9]

The following tables show which point sources are controlled in the CENRAP states that the MPCA has identified as contributing to visibility impairment in BWCAW and VNP (Iowa, Minnesota, Missouri) under the following assumptions: 1) a cost less than $5000/ton, and 2) facility emissions divided by the facility's distance from any Class I area, is greater than or equal to five (often called the Q/5D criteria). The tables include sources that are within Q/5D of either VNP or BWCAW.

The report prepared for the MPCA and Midwest RPO by EC/R, entitled "Reasonable Progress for Class I Areas in the Northern Midwest – Factor Analysis," also provides documentation that the various control strategies mentioned in Attachment 2 are likely to be reasonable, at least for some states. A summary table follows the tables of units controlled in the CENRAP control sensitivity run.[10]

---

[9] Information on the Control Sensitivity run is available on CENRAP's Project website, http://www.cenrap.org/projects.asp, under the link entitled *Results from Control Sensitivity Run, Base18Gc1 - Cost Curve Criteria of 5k per ton, Q over 5D*

Re: Northern Class I Areas Consultation
Conclusion Memorandum

Dear Mr. Moore:

We have reviewed your memorandum of September 19, 2007 regarding consultation with States that have sources which emit air contaminants which impact visibility (regional haze) in the Voyageurs National Park and Boundary Waters Canoe Area Wilderness. The State of North Dakota is committed to addressing regional haze in accordance with the requirements of the Clean Air Act. This includes an evaluation of appropriate emission limitations under the Best Available Retrofit Technology (BART) requirements [40 CFR 51.308(e)] as well as the other requirements [40 CFR 51.208(d)-(i)]. This will include an assessment of additional emission reductions from electric utility steam generating units and other source categories unaffected by the BART requirements. This assessment will be conducted as prescribed in the Regional Haze rule.

In your memorandum, you requested that North Dakota "evaluate further reductions of SO_2 from electric generating units (EGU) in order to reduce SO_2 emissions by 2018 to a rate that is more comparable to the rate projected in 2018 from Minnesota, approximately 0.25 lbs/MMBTU". You also requested that North Dakota evaluate the potential for reductions of NO_x from EGUs due to predicted higher NO_x emission rates compared with Minnesota and other contributing states. We believe that the use of lb/MMBtu as the metric for seeking additional emission reductions is flawed. The North Dakota EGUs are located more than 500 kilometers from Voyageurs National Park and further from the Boundary Waters Canoe Area Wilderness. The EGUs in Minnesota are located much closer and will have a much greater impact on visibility in the Minnesota Class I areas for a given emission rate (e.g. lb/MMBtu or tons/yr). Given the proximity of the sources located in Minnesota and the major contribution those sources have on the Class I areas in

Minnesota, we believe Minnesota should closely examine the impact on visibility of those sources as compared to the impact of sources in neighboring states. Additional reductions from Minnesota sources may provide much greater reduction of visibility impacts. The lb/MMBtu metric, if retained, should be adjusted to take into account the actual visibility impact of the neighboring states sources.

In reviewing your memorandum, the EGU Summary for 2018 (p.12) indicated that the "IPM3.0-will do" scenario predicts a reduction of SO_2 and NO_x emissions from Minnesota EGUs of 83,757 tons per year (44.7%) while North Dakota EGUs will reduce emissions by 106,859 tons per year (48.2%). Yet, Attachment 1 to your memorandum indicates Minnesota sources contribute 25.4-37.6% of the baseline visibility impairment (depending on the Class I area, the time period, and the group doing the modeling) while North Dakota sources only contribute 4.8-7.1%. We believe the substantial reductions of sulfur dioxide and nitrogen oxides from North Dakota EGUs will assist Minnesota in making reasonable progress toward the national visibility goal.

The lb/MMBtu metric is also flawed because it does not account for the type of fuel burned or the firing configuration of the EGU. The EGUs in North Dakota primarily fire lignite which has a higher sulfur content than subbituminous coal. This requires a higher removal rate of SO_2 to achieve MPCA's 0.25 lb/MMBtu benchmark than it would for Minnesota sources. In addition, four of the EGUs in North Dakota are cyclone fired units which have much higher uncontrolled NO_x emission rates than other pulverized coal fired units. The constituents of the North Dakota lignite (e.g. soluble sodium in the ash) makes it much more difficult and expensive to control NO_x emissions. Again, greater reductions would be required for North Dakota sources to achieve the MPCA's benchmark than for Minnesota EGUs.

Your memorandum of September 19, 2007 suggests that Minnesota is counting on reductions from the Clean Air Interstate Rule (CAIR) by stating "In addition to on-the-books controls, such as the Clean Air Interstate Rule (CAIR), Minnesota expects....". Given the recent vacature of CAIR, such reliance on reductions may be premature. In addition, your request for additional reductions from other states should be reevaluated.

In summary, we believe the metric (lb/MMBtu) for asking other states to make additional emission reductions is inappropriate. North Dakota will continue to seek appropriate emissions reductions commensurate with the law and available technology. Through the effort of each state significant improvements in air quality will be achieved. As we work through the process, we will afford you more opportunities to discuss our State Implementation Plan (SIP) and the emission reductions that will be achieved. North Dakota's SIP is expected to be available by the end of this year.

If you have any questions, please feel free to contact me at (701)328-5150.

Respectfully,

L. David Glatt, Chief

RE: EPA Region 8 Comments on May 2008 Draft BART SIP (FLM Consultation Version)

Dear Terry:

EPA has completed a preliminary review of North Dakota's May 2008 draft Regional Haze SIP to meet Best Available Retrofit Technology (BART) requirements ("BART SIP"), as requested via email by Tom Bachman on June 2, 2008. Our comments and questions are detailed in Enclosure 1 to this letter. For the record, we are also including the numerous comments we've made previously on the company BART analyses that are now contained in Appendix C of the BART SIP (see Enclosure 2). We understand that you intend to consider all comments received on this Federal Land Manager (FLM) consultation version of the BART SIP prior to finalizing the documents. The final draft of the BART SIP, which will include a summary of the FLMs' comments and your responses, will then undergo a broader public hearing process prior to adoption and submission to EPA. We emphasize that we will only come to a final conclusion regarding the adequacy of North Dakota's BART determinations and SIP when we act on the North Dakota Regional Haze SIP revision, through our own public notice and comment rulemaking.

We want to acknowledge your tremendous efforts in developing BART for the subject-to-BART electric generating units in North Dakota and in working up front with us as issues arose. For the most part, your draft SIP is comprehensive and contemplates commendable reductions - approximately 90,000 tons/year SO_2 and 21,000 tons/year NO_x based on our calculations using current actual annual emissions minus BART emission limits. Our comments are meant to ensure that the relevant BART analyses and determinations are robust and well-supported and that the SIP is in a form we can approve. We hope that you will give consideration to our comments to assure truly "best available" BART levels and reasonable progress toward the National visibility goal.

You have previously indicated that the remainder of the Regional Haze SIP requirements, including reasonable progress and the long-term strategy, will be addressed separately, and we look forward to working with you on those SIP revisions. Please be aware that a BART SIP alone probably will not be adequate to avoid a finding of failure to submit the Regional Haze SIP by the required due date. Such a finding would initiate a 2-year clock for the completion of a Federal Implementation Plan to address any outstanding regional haze requirements.

We have appreciated working with you during the review of this FLM consultation version of the draft BART SIP and look forward to continued communications during the public hearing process. If you have any questions on EPA's comments, please contact me at 303-312-6434, or have your staff contact Amy Platt at 303-312-6449.

Sincerely,

Callie A. Videtich, Director
Air Program

ENCLOSURE 1

EPA Region 8 Preliminary Comments on May 2008 Draft BART SIP (FLM Consultation Version)

Summary of Major Concerns - (see detailed comments for more information):

1. There are numerous inconsistencies between the SIP text, North Dakota Department of Health (NDDH) BART determinations, and proposed permits regarding the BART limits. Please clarify/resolve.
2. We disagree regarding the technical feasibility of SCR for NO_x control at the 3 cyclone units burning North Dakota lignite (Milton R. Young Units 1 & 2 and Leland Olds Unit 2).
3. NDDH's Leland Olds 5-factor analysis lacks SO_2 cost and visibility analyses for Unit 2.
4. NDDH's Milton R. Young 5-factor analysis lacks NO_x visibility analyses entirely and relies on an incomplete BACT process to satisfy BART analysis requirements.
5. Startup/shutdown exemption for Milton R. Young NO_x limit is not acceptable.
6. We believe that the inferior control technology proposed for Stanton Unit 1 (spray dryer/fabric filter), coupled with what we find to be an inflated uncontrolled emission rate, produces too high of an SO_2 limit (0.24 for lignite, 0.16 for PRB). Although this is the smallest of the subject-to-BART units in terms of megawatts, this and other power plants are among the largest emitters in the State. It may be more cost-effective to consider further controls now in order to meet reasonable progress requirements, rather than waiting to address these requirements with other sources during the development of the remainder of your Regional Haze SIP.

Detailed Comments

BART SIP text:

1. Definitions, pp. 11-15: Definitions are accurately cited from 40 CFR 51.301, however, each definition is designated by letter (*e.g.*, hh, e, w, d, l, m, etc.). Since 40 CFR 51.301 does not assign letters to the definitions, what is the basis for these letter designations? In addition, we suggest rewording 1st sentence on p. 13 to clarify that the definition for "existing stationary facility" is much broader than simply "a stationary source."
2. Screening Impact Threshold, pp. 16-17: A more robust discussion regarding NDDH's process for selection of the 0.5 deciview threshold should be provided to justify your selection. For example, the addition of a discussion of the number and relative impacts of BART-eligible units above and below 0.5 deciviews, and the potential for plume overlap due to the relative clustering of sources, would be useful.

3. Exclusion of Montana Dakota Utilities Heskett Unit No. 2, p. 23:
   (A)We have concerns with ENSR's CALPUFF modeling. They reduce the CALMET/CALPUFF grid size from 3 km to 1 km. EPA has recently seen data indicating that Calpuff may inappropriately reduce predicted concentrations with such grid size manipulation. In addition, ENSR's use of annual average background visibility conditions will also decrease delta deciview impacts. According to NDDH's approved "Protocol for BART-Related Visibility Impairment Modeling Analyses in North Dakota," the 20% cleanest days should be used. Given that ENSR's refined results move Heskett from "subject-to-BART" to "exempt," a more robust discussion is necessary regarding why NDDH found ENSR's analysis "acceptable," including an explanation of why you think this approach will not lead to underestimates of visibility impacts.
   (B) NDDH notes that MDU has committed to increase SO_2 removal efficiency to a minimum of 70% by 2013. How is this voluntary agreement formalized? We note that in a June 9, 2006 letter from MDU to Terry O'Clair, they commit to "control SO_2 emissions by installing and operating the necessary equipment to use limestone as the bed material in the boiler." They state that they will agree to include a condition in their Title V permit implementing this change, including a permit shield pertaining to BART applicability. Is NDDH taking credit for these emissions reductions in the BART SIP, *i.e.*, are these reductions included in the 99,000 tons/year figure provided in the SIP text? Does NDDH intend to use these reductions to satisfy reasonable progress requirements? If so, how do you intend to make this agreement federally enforceable?
4. SO_2 BART Determinations, pp. 24-26: As we have commented previously, we would like you to consider establishing limits that require the BART units to meet both lb/MMBtu emission rates *and* control efficiencies, rather than just one *or* the other. The potentially cost-effective additional reductions you can achieve now by having both limits apply to these large sources will be beneficial toward meeting reasonable progress requirements during the development of the remainder of your Regional Haze SIP.
5. SO_2 discussion on p. 25-26 doesn't match the table on p. 33, *e.g.*, the 90% reduction requirement for Milton R. Young Unit 2 is not included in the text, nor is the separate PRB limit for Stanton included in the table (see more detail below under source BART determination specific comments).
6. NO_x discussion on p. 27 states that "[t]he seven BART sources determined SCR is not technically feasible for installation on boilers in North Dakota burning lignite coal." However, this statement is inconsistent with the Great River Energy BART analyses which found low-dust SCR feasible for the units burning lignite at their Coal Creek and Stanton Station facilities.
7. NO_x BART section: In the absence of a final NO_x BACT determination under the Consent Decree process for Minnkota's Milton R. Young facility, a full 5 factor NO_x BART analysis is required for Milton R. Young in the BART SIP. If a final BACT decision is reached, and NDDH wants to rely on the BACT determination to satisfy BART, NDDH will need to include a discussion of BACT as a surrogate for BART in this section of the BART SIP text.
8. Tables 3 & 4, regarding SO_2 and NO_x emissions reductions, pp. 32-34: These tables are

confusing in that the BART level of control (% reduction) column is not easily reproduced from the data presented. These tables should be revised for more transparent public review.

9. Section 3.5, Air Pollution Control Permit to Construct for Subject-to-BART Sources, pp. 34-36: (A) NDDH indicates that emission limits, monitoring, recordkeeping, and reporting requirements specified in the BART determinations are included in federally enforceable permits to construct that will be issued to the owner/operator of the facility before the SIP is submitted to EPA. Later, the text indicates that the four permits are included in Appendix D. As we have commented previously, the limits, monitoring, recordkeeping, and reporting requirements must be part of the SIP. For the sake of clarity, the text in section 3.5 should state that the four permits are included in Appendix D and are incorporated "as part of this SIP." (B) The public notice for the BART SIP needs to include notification that the BART permits are included.
10. Section 4.3, Consultation with Other States, pp. 37-38: We note that in its September 19, 2007 Northern Class I Areas Consultation Conclusion, the Minnesota Pollution Control Agency determined that North Dakota is a significant contributor to visibility impairment at both Voyageurs National Park and Boundary Waters Canoe Area Wilderness. As a result, Minnesota requested that North Dakota evaluate further reductions of SO_2 and NO_x emissions from its electric generating units (EGUs). We understand that you were a participant in that process, in part to meet the state-to-state consultation requirements under the regional haze rule. EPA will be evaluating Minnesota's and North Dakota's Regional Haze SIPs to assess both Minnesota's request that you evaluate further reductions of emissions from EGUs, and your response to that request.
11. Appendix B.5, BART SCR Technical Feasibility Analysis for ND Lignite: As we have commented previously, we do not agree with your rationale for determining that SCR is technically infeasible when burning North Dakota lignite. We have done a thorough review of the technical feasibility analyses submitted by Minnkota for Units 1 and 2 at Milton R. Young Station and NDDH's preliminary BACT determination published for public notice on June 11, 2008. Our comments and supplemental information were provided in a July 31, 2008 letter from Andrew M. Gaydosh, Assistant Regional Administrator, Office of Enforcement, Compliance, and Environmental Justice, to Terry O'Clair, Director, North Dakota Department of Health, Division of Air Quality. Our letter provided substantial information and evidence that the SCR technology is technically feasible at facilities burning North Dakota lignite.
12. Appendix E, Public Hearing Record: need to ensure that E.8, Response to Public Comments, includes a summary of all public comments received as well as the State's response.

Chapter 33-15-25 Regional Haze Requirements:

13. 33-15-25-02.2: insert "part 51" before "section 301."
14. 33-15-25-04: This section cross references the State's Acid Rain Program (33-15-21) and Title V Program (33-15-14-06), neither of which is included in the federally approved SIP.

This may not be problematic if the specific requirements are spelled out in the SIP text and permits. If the requirements are not spelled out in the SIP text and permits, then the specific requirements need to be specified in this rule or the rule should cite to the federal regulations.

NDDH BART Determinations – Pertaining to All 4 Determinations

15. SO_2 analyses, Step 2: Eliminate Technically Infeasible Options: The arguments presented for Coal Cleaning/Washing and K-Fuel go more to environmental impacts and economic concerns than to technical feasibility. In addition, NDDH provides only a cursory discussion of the commercial history of the K-Fuel technology and vendor and source experiences. It's not clear whether the technology has been successfully employed elsewhere, or why or whether coal type, or the specific source mine, is really a significant distinguishing factor. Also, for TurboSorp, NDDH cites lack of commercial availability in the U.S., but this begs the question whether it's been in commercial use elsewhere. Based on the limited discussion presented, EPA wouldn't necessarily concur with NDDH's conclusion that these options are technically infeasible. Additional information should be provided to support the technical infeasibility determination, or it may be more appropriate to discuss your concerns under the analysis sections for cost effectiveness and/or energy and non-air quality impacts.
16. The References section should include a cite to the company BART analyses that were relied upon by NDDH in preparing these determinations. While we realize that Appendix C of the BART SIP incorporates the company analyses, the BART determinations should also reference them for ease of public review.

NDDH Proposed Permit to Construct for BART – Pertaining to All 4 Permits

The proposed permits were reviewed against the draft "model" BART permit format NDDH developed in March 2008. Concerns with deviations from that format are discussed here as applicable to all four proposed permits. Deviations of concern to specific proposed permits are addressed below under comments for the specific facilities.

17. II.A.1., 1st paragraph: Added a new last sentence citing to 40 CFR Part 60, Subpart Da. As our staffs have discussed, we recommend deleting all references to Da since the relevant language from Da on how to calculate 30-day rolling averages is already spelled out in the permit, and since the references to Da are problematic. The specific subsections of Da that describe how to calculate 30-day rolling averages also contain exemptions from emission limits for startup, shutdown and malfunction. We are concerned that the references to Da could be construed by permittees to mean BART sources get those same exemptions from BART limits, even though the permits say elsewhere that the BART limits apply at all times. An alternative would be to put a statement in the permits that the exemptions in Da do not apply to BART limits, but as we have noted, the references to Da do not appear to be necessary in the first place. The references to Da are also problematic since Da explicitly

prohibits use of Part 75 for data substitution procedures, whereas condition II.A.4.b.(3) of the BART permits allows it.

18. II.A.4.b.(7), Notes: Added a reference to Condition II.A.1. under 30-day rolling average which refers back to Da. This reference is problematic if the concerns noted above in II.A.1. are not corrected. However, if II.A.1. is corrected as described above, then the reference in II.A.4.b.(7), Notes, is a good idea.
19. II.A.6.g.: To avoid the implication that the source can determine the effective date of the BART emission limits, the phrase "and the effective date of the BART emission limits" should be deleted from the end of the sentence. Based on conversations between our staffs, we understand that you have agreed to this change.

Leland Olds:

NDDH BART Determination

20. Unit 1 SO_2 BART evaluation: On p. 8, the emission factor for SO_2 is incorrectly stated as 35S. EPA's AP-42 states that for lignite firing (either wall-fired or cyclone boilers), the emission rate is 30S. It appears that NDDH's calculations for both the corrected and uncorrected emission rates are too high.
21. Unit 2 SO_2 BART evaluation: NDDH determines that because the "most efficient control option" was selected for SO_2 control, no evaluation of costs or visibility impacts is necessary. This approach does not meet the BART Guideline requirements for analysis. In fact, a full 5-factor analysis may find that even stricter controls would be cost effective and/or provide greater visibility benefits.
22. Unit 1 NO_x BART evaluation: It is not clear how some of the 16 control options listed were eliminated from further consideration. However, the selection of SNCR plus SOFA at 0.19 lbs/MMBtu is a commendable level of control.
23. Unit 2 NO_x BART evaluation: NDDH determined that SCR is not technically feasible. As you know, we disagree with this conclusion, based on our analyses related to Milton R. Young NO_x BACT, analyses performed to support the BART Guidelines, and other sources of information. We note that NDDH, in reaching its conclusion regarding technical infeasibility of SCR, relies on the Milton R. Young NO_x BACT evaluation; however, the Milton R. Young BACT process has not been completed.
24. Page 39: Typo in table heading – should be Unit 2?
25. Summary, p. 44-45: Units 1 and 2 PM limits are listed as 0.05 lbs/MMBtu; however, the text of the PM BART evaluation and the proposed Permit to Construct for BART lists 0.07 lbs/MMBtu. Please clarify.
26. Summary, p. 44-45: Unit 1 NO_x limit is listed as 0.18 lbs/MMBtu with 849 tons/yr emissions reductions; however, the NO_x BART evaluation lists 0.19 lbs/MMBtu as the limit and the BART SIP text, Table 4, lists 757 tons/yr emissions reduction. The proposed Permit to Construct for BART also lists the limit as 0.19. Please clarify.

27. We appreciate the revision to the visibility impacts analysis to present the required 98th percentile results, as previously requested.

NDDH Proposed Permit to Construct for BART – Leland Olds

28. II.A.1.c., PM emission limits: The expression "Unit 1 and Unit 2" is problematic since it could be construed to mean emission averaging across both units is allowed. For clarity, we recommend NDDH list the Units and the applicable PM limits individually.
29. II.A.4.b.(5): The phrase "EPA-approved" was deleted from the last sentence regarding other test methods and should be corrected.
30. II.A.4.b.(8): Added "Average AER" equation and allowable emission rate. Based on a conversation between our staffs, we understand that you have agreed to add a footnote clarifying that "Average ER = average actual emission rate," so as not to confuse it with "AER" which is "allowable emission rate."
31. II.A.6.d.: There appears to be an inadvertent deletion of the phrase "or portable analyzer test." Based on a conversation between our staffs, we understand that this will be corrected.

Coal Creek:

NDDH BART Determination

32. We believe there may be an error in the computation used in the Future Case table, p. 10. Uncontrolled SO_2 emissions are scaled up by the ratio of 1.1%/0.61%, to account for dried vs. as-received lignite, to yield 76,888 tons/yr. This fails to recognize that Btu content will increase by the same ratio, thus, requiring less total tonnage of lignite to be burned. If an error was made, these calculations should be redone. The Future Case table also has 2 rows labeled "Existing Scrubber & 27% Bypass," having control efficiencies of 68% and 83.1%. The first label should be changed and the scenario should be described.
33. SO_2 analyses, Step 6: Select BART, p. 12: We do not agree with NDDH's characterization of the degree of visibility improvement (0.263 deciviews) achieved by selecting wet scrubber replacement versus wet scrubber modification as a "negligible improvement." We note that NDDH selected a wet scrubber over a spray dryer in the Leland Olds BART determination, with a visibility improvement of 0.198 deciviews. In addition, it may be difficult to achieve similar visibility improvement more cost effectively for purposes of reasonable progress.
34. The NPS has raised concerns over Great River Energy's (GRE's) inclusion of almost $14 million infrastructure "sunk costs" in its analysis of future economic costs for SCR and SNCR. We understand that you are continuing your discussions with GRE regarding the potential loss of future ash sales and cost of future ash disposal and expect to provide additional information. We will review any additional information when it becomes available.

NDDH Proposed Permit to Construct for BART – Coal Creek

35. II.A.1.c.: We note that the PM limit is worded as applicable to "either Unit 1 or Unit 2." The expression "either Unit 1 or Unit 2" is problematic since it could be construed to mean that compliance must be demonstrated at only one of the two units. For clarity, we recommend that NDDH list the Units and the applicable PM limits individually.

Milton R. Young

NDDH BART Determination

36. Minnkota's August 2007 analyses appear to rely heavily on Consent Decree (CD) options. As we have noted in previously submitted comments, the language of the CD does not indicate that EPA considered the controls to be BACT or BACT-equivalent. The BART analyses need to be a robust review of control technologies – not a validation of what was already agreed to in the CD.
37. SO_2 BART evaluation: Unit 1 visibility impacts for the 90th percentile are referenced from the source's August 2007 BART analysis, and the reader is directed to extrapolate the required 98th percentile results from Appendix A of that document. This is not an adequate presentation of the required 98th percentile results. See previously submitted comments.
38. NO_x BART evaluation:
(A) The startup/shutdown exemption and separate limits for these periods are not acceptable. The BART Guidelines contemplate pounds per million Btu limits that apply continuously, with a 30-day rolling average period. Minnkota argues that SNCR does not function properly during startup and shutdown periods when operating outside of a specified temperature range. We understand that various types of control technologies, including SNCR, may not be fully effective outside specified temperature ranges. However, one of the purposes of a 30-day averaging period for the BART limits is to accommodate potential short-term fluctuations in the emissions rate that may result during startups and shutdowns and other conditions. NDDH indicates that, if historical worst-case startup durations occur, compliance with the 30-day rolling average limits will be "extremely difficult;" NDDH does not say it would be impossible. It is not clear what steps, if any, Minnkota may have taken historically to reduce emissions during startups or to limit the duration or frequencies of startups. NDDH does not indicate why startups lasted 61 or 115 hours, whether such durations were typical, or how frequently they occurred. We are concerned that NDDH's proposed approach could result in a very large NO_x emission event with resultant visibility impacts and no real incentive for Minnkota to minimize its emissions during startup and shutdown. We do not believe that startup/shutdown exemptions are necessary or appropriate for Milton R.Young's 30-day NO_x BART limits and that the exemptions should be eliminated. We also note that the same exemptions have not been sought by, or provided to, other facilities (Leland Olds & Stanton) for which SNCR is proposed as BART, and we know of no reason Milton R. Young warrants

special treatment. Leland Olds Unit 2 is also a cyclone unit.

(B) No visibility impacts analyses are provided since the source proposed the "most efficient technology." First, we do not agree that the most efficient technology was selected since SNCR is proposed instead of SCR. Second, this approach does not meet the BART Guidelines requirements for a full 5-factor analysis and should be corrected. A full analysis may find that stricter controls provide greater visibility benefits.

(C) We believe that the presumptive limits should apply since the total generating capacity is actually greater than the reported nameplate capacity of 734 MW, in fact, > 750 MW (see previously submitted comments).

(D) On p. 21, NDDH refers to a "completed" BACT determination and on p. 45, the preliminary BACT determination is incorporated by reference. However, the NO_x BACT process is not completed, and as we have commented previously, NDDH cannot rely upon an incomplete BACT process to satisfy the BART analysis requirements. Therefore, the NO_x BART analysis for Milton R. Young is deficient.

39. Summary, p. 51: The Unit 2 SO_2 limit does not list the minimum 90% reduction with the 0.15 lbs/MMBtu limit, as is presented in both the table in the SIP text on p. 33 and in the proposed Permit to Construct for BART. Please clarify.

NDDH Proposed Permit to Construct for BART – Milton R. Young

40. II.A.1.c., NO_x limits: The startup/shutdown exemption and separate limits for these periods are not acceptable. See discussion above in comment #38(A).
41. II.A.1.c., PM limits: The expression "Unit 1 and Unit 2" is problematic since it could be construed to mean emission averaging across both units is allowed. For clarity, we recommend that NDDH list the Units and the applicable PM limits individually.
42. II.A.1.e.: The condition that SO_2 and PM limits apply at all times, including startup, shutdown, emergency and malfunction should also apply to NO_x limits.
43. II.A.4.b.(5): The phrase "EPA-approved" has been deleted from the last sentence regarding other test methods and should be corrected.

Stanton:

NDDH BART Determination

44. SO_2 BART evaluation in general: We believe that the proposed technology (spray dryer/fabric filter) is inferior, and coupled with what we find to be an inflated uncontrolled emission rate, results in SO_2 limits that are too high (0.24 for lignite, 0.16 for PRB coal). A lower emission limit can be achieved by using a more realistic uncontrolled rate and increasing the design removal efficiency. Although this is the smallest of the subject-to-BART units in terms of megawatts, this and other power plants are among the largest emitters in the State. It may be more cost-effective to consider further controls now in order

to meet reasonable progress requirements, rather than waiting to address these requirements with other sources during the development of the remainder of your Regional Haze SIP.

45. SO_2 BART evaluation for lignite: (A) On p. 8, NDDH uses an uncontrolled emission rate of 2.4 lbs/MMBtu for calculation of BART limits. This number appears to be inflated since a value of 1.81 lbs/MMBtu is used on p. 4 and the highest year's value from CAMD (prior to the fuel switch) was 1.92 lbs/MMBtu. (B) A wet scrubber was eliminated from consideration based on environmental considerations, but it is not clear how significant these other considerations were and why they were not significant at any other plant. Please explain. We believe that consideration should be given to using a wet scrubber.
46. SO_2 BART evaluation for PRB coal: On p. 22, a possible future sulfur content of 1.6 lbs/MMBtu is used to calculate the BART limit. We find this assumption unrealistic given that recent content at Stanton, since the switch to PRB coal, is closer to 0.5 lb/MMBtu. Please clarify if you disagree or provide a more realistic assumption for future sulfur content.
47. The SO_2 analyses do not address the scenario for when a combination of PRB coal and lignite are burned, although this scenario is included in the proposed permit to construct for BART. If NDDH intends to keep this option in the permit, then the BART determination must include the necessary analyses.
48. NO_x BART evaluation for lignite and PRB coal: (A) On pp. 13 & 24, the amount of emission reductions that can be achieved is underestimated in these tables. Greater control efficiencies are generally achieved by combining combustion controls plus SNCR. (B) The State's proposal of LNB+OFA+SNCR is commendable since it goes beyond what can be achieved with just combustion controls. However, the BART limit should be tightened since current (pre-BART) emissions using PRB coal at Stanton are already very close to the proposed limit (0.26 lb/MMBtu vs. 0.23 lb/MMBtu).
49. PM BART limit: We note that the proposed spray dryer/fabric filter would reduce PM emissions as well, but the BART determination does not seem to account for it in the proposed PM limit.
50. Summary table, p. 27: (A) The SO_2 limit provided for PRB coal is not listed in the table of the SIP text, p. 33. (B) Neither this summary table nor the SIP text, p. 33, includes the SO_2 and NO_x limits when a combination of lignite and PRB coal are burned, even though the proposed permit does include these "combination" limits. Please clarify/resolve these inconsistencies.

<u>NDDH Proposed Permit to Construct for BART – Stanton</u>

51. II.A.1.c. and II.A.1.f: These calculations for determining the SO_2 and NO_x limits when a combination of lignite and PRB coals is burned do not seem consistent with the language in the SIP text, pp. 24 & 26, which states that the limits are the same whether burning PRB coal alone or in any combination with lignite. Please clarify/resolve this inconsistency.
52. II.A.1.g.: There appears to be a typo in the last sentence. The reference should be to II.A.4.b.(5), not III.A.4.b.5.
53. II.A.4.b.(5): The phrase "EPA-approved" was deleted from the last sentence regarding other

test methods and should be corrected.

54. II.A.4.b.(7): A cross-reference to II.A.1.c. should be included. Based on conversations between our staffs, we understand that you have agreed to make this change.

ENCLOSURE 2

Previously Submitted Region 8 Comments on Company BART Analyses

1. November 1, 2006 letter from Richard R. Long, EPA Region 8, Air & Radiation Program, to Terry O'Clair, NDDH, Division of Air Quality, regarding comments on draft BART analyses.
2. November 7, 2007 letter from Callie A. Videtich, EPA Region 8, Air & Radiation Program, to Terry O'Clair, NDDH, Division of Air Quality, regarding comments on revised Minnkota BART analyses.
3. December 19, 2007 email message from Amy Platt, EPA Region 8, Air & Radiation Program, to Craig Thorstenson, NDDH, Division of Air Quality, regarding comments on revised Stanton BART analyses.
4. February 26, 2008 email message from Amy Platt, EPA Region 8, Air & Radiation Program, to Craig Thorstenson, NDDH, Division of Air Quality, regarding comments on revised Stanton BART analyses.

Response to August 4, 2008 EPA BART Comments for Stanton Unit 1

Comments 44-50 apply to the Department's BART Determination

Comment #44:

We believe that the proposed technology (spray dryer/fabric filter) is inferior, and coupled with what we find to be an inflated uncontrolled emission rate, results in SO_2 limits that are too high (0.24 for lignite, 0.16 for PRB coal). A lower emission limit can be achieved by using a more realistic uncontrolled rate and increasing the design removal efficiency. Although this is the smallest of the subject-to-BART units in terms of megawatts, this and other power plants are among the largest emitters in the State. It may be more cost-effective to consider further controls now in order to meet reasonable progress requirements, rather than waiting to address these requirements with other sources during the development of the remainder of your Regional Haze SIP.

Response to Comment #44:

The Department agrees that higher SO_2 control efficiencies can be attained. Control technologies with higher SO_2 removal efficiencies (a wet scrubber and a circulating dry scrubber) were included in the BART analyses for both lignite and PRB coal combustion. As indicated in the BART determination, these technologies were eliminated from consideration as BART due to economic and environmental considerations.

The Department's economic analyses were based on uncontrolled annual SO_2 emissions of 1.81 lb/million Btu for lignite and 1.2 lb/million Btu for PRB coal. The proposed BART emission limits for SO_2 are based on a 30-day rolling average (as opposed to an annual average) with 90% reduction and also includes emissions from startups, shutdowns and malfunctions. Based upon historical SO_2 emissions data for spray dryers and fabric filters at facilities burning North Dakota lignite, we have determined that an increase of 33% is warranted to adjust from an annual average SO_2 emission rate to a 30-day rolling average emission rate. The discussion regarding potential SO_2 emission rates as high as 2.4 lb/million Btu for lignite and 1.6 lb/million Btu for PRB coal was intended to show that higher sulfur coal could be encountered (see Appendix E, Sulfur Content Statistical Analysis, of the GRE BART Analysis).

The EPA also states, "it may be more cost-effective to consider further controls now in order to meet reasonable progress requirements...". This statement appears to be based almost entirely on speculation as EPA provides no basis for the comment. In addition, the Guidance for Setting Reasonable Progress Goals Under the Regional Haze Program states, "Note that for some sources determined to be subject to BART, the State will already have completed a BART analysis. Since the BART analysis is based, in part, on an assessment of many of the same factors that must be addressed in establishing the RPG, it is reasonable to conclude that any control requirements imposed in the BART determination also satisfy the RPG-related requirements for source review in the first RPG planning period. Hence, you may conclude that no additional emissions controls are necessary for these sources in the first planning period".

Comment # 45(A):

On p. 8, NDDH uses an uncontrolled emission rate of 2.4 lbs/MM Btu for calculation of BART limits. This number appears to be inflated since a value of 1.81 lbs/MM Btu is used on p.4 and the highest year's value from CAMD (prior to the fuel switch) was 1.92 lbs/MM Btu.

Response to Comment #45(A):

This comment is addressed in the Department's response to Comment #44 above.

Comment #45(B):

A wet scrubber was eliminated from consideration based on environmental considerations, but it is not clear how significant these other considerations were and why they were not significant at any other plant. Please explain.

Response to Comment #45(B):

The Department eliminated a wet scrubber from consideration as BART at Stanton Unit 1 based upon a combination of factors. These include the relatively high incremental cost of $4,179 per ton of SO_2 removed when burning lignite and $6,302 per ton of SO_2 removed when burning PRB, the additional environmental impacts of a wet scrubber and the fact that a wet scrubber will remove a relatively small amount of SO_2 when compared to a spray dryer (with a small corresponding visibility improvement).

The additional environmental considerations are further outlined below:

- A wet scrubber is estimated by GRE to use as much as 20% more water or approximately 15 million gallons per year of additional water.

- It is assumed that a wet scrubber system will require additional on-site ponding. GRE has identified two potential areas on site that could be used for the additional ponding. The areas include the existing ash pile, which would have to be excavated and moved, or the abandoned ash disposal area adjacent to the river, which reportedly has geotechnical deficiencies.

- Dry scrubbers are purported to achieve a higher mercury control efficiency on lignite and PRB as compared to a wet scrubber. In addition, future mercury control requirements could result in high concentrations of mercury in the ponds and prove problematic to discharge.

Comment #46:

On p. 22, a possible future sulfur content of 1.6 lb/MM Btu is used to calculate the BART limit. We find this assumption unrealistic given that recent content at Stanton, since the switch to PRB coal, is closer to 0.5 lb/MM Btu. Please clarify if you disagree or provide a more realistic assumption for future sulfur content.

Response to Comment #46:

The sulfur content of coal varies considerably. The sulfur content of the PRB coal recently combusted at GRE Stanton has no bearing on the sulfur content of coal which might be burned at the facility in the future. Based on the data contained in Appendix E, Sulfur Content Statistical Analysis, of the GRE BART Analysis, the Department considers a future sulfur content of 1.6 lb/MM Btu to be realistic.

Comment #47:

The SO_2 analyses do not address the scenario for when a combination of PRB coal and lignite are burned, although this scenario is included in the proposed permit to construct for BART. If NDDH intends to keep this option in the permit, then the BART determination must include the necessary analyses.

Response to Comment #47:

The BART analyses were conducted assuming 100% lignite combustion and 100% PRB coal combustion. Since the same control technologies were chosen for both scenarios, any BART analysis conducted assuming a blending of lignite and PRB coal would result in the choice of the same control technologies as BART. The Department has included language in the BART determination addressing the limits when combusting lignite and PRB coal in combination. It should be noted that GRE has indicated that lignite and PRB coal will likely only be burned in the same 30-day averaging period during a switch from one coal to another (i.e., fuel blending is not likely to occur on an extended basis).

Comment #48(A):

On pp. 13 and 24, the amount of emission reductions that can be achieved is underestimated in these tables. Greater control efficiencies are generally achieved by combining combustion controls plus SNCR.

Response to Comment #48(A):

The EPA states that the amount of NOx emission reductions that can be achieved are generally underestimated in the BART determination; however, the EPA provides no information supporting this statement. The Department has determined that the control efficiencies assumed are reasonable and the EPA provided no information to the contrary.

Comment #48(B):

The State's proposal of LNB+OFA+SNCR is commendable since it goes beyond what can be achieved with just combustion controls. However, the BART limit should be tightened since current (pre-BART) emissions using PRB coal at Stanton are already very close to the proposed limit (0.26 lb/MM Btu vs. 0.23 lb/MM Btu).

Response to Comment #48(B):

EPA states that "current (pre-BART) emissions using PRB coal at Stanton are already very close to the proposed limit (0.26 lb/MMBtu vs. 0.23 lb/MMBtu)". As with the SO_2 emission rates, the EPA fails to distinguish between annual emissions and 30-day rolling average emissions. Also, the most recent annual average annual NOx emission rates from Stanton Unit 1 for 2006 and 2007 are 0.28 lb/MM Btu, not 0.26 lb/MM Btu.

There exist operational considerations at Stanton Unit 1 which are likely to affect the NOx emission rate on a short-term basis. These operational considerations are summarized below:

- Under normal operating conditions, Unit 10 is run at full utilization while Unit 1 varies (swings) to meet Midwest Independent System Operators (MISO) power demands. These load swings can impact NOx emissions on a short-term basis.

- If Unit 10 trips due to a tube leak or other maintenance problem, Unit 1 needs to operate all three mills in order to fully supply steam to the single turbine. Under the three mill operational scenario, NO_x emission rates are higher than under the two mill scenario. It is possible for Unit 1 to operate on all three mills for as much as 30 days.

- Nitrogen can vary by coal type, which will impact NO_x emissions.

Comment #49:

We note that the proposed spray dryer/fabric filter would reduce PM emissions as well, but the BART determination does not seem to account for it in the proposed PM limit.

Response to Comment #49:

As indicated in the BART determination, BART for filterable PM for both lignite and PRB coal is proposed as no additional control due to the prohibitive cost of additional PM controls and the insignificant visibility improvement expected from additional PM controls. The fact that a spray dryer / fabric filter is being installed to control SO_2 emissions is a separate issue and does not affect the BART determination for PM.

Comment #50:

Summary table, p. 27: (A) The SO_2 limit provided for PRB coal is not listed in the table of the SIP text, p. 33. (B) Neither this summary table nor the SIP text, p. 33, includes the SO_2 and NO_x limits when a combination of lignite and PRB coal are burned, even though the proposed permit does include these "combination" limits. Please clarify/resolve these inconsistencies.

Response to Comment #50:

The SIP has been corrected to account for the different proposed limits.

Comments 51-54 Apply to the Proposed Permit to Construct for Stanton Unit 1

Comment #51:

II.A.1.c. and II.A.1.f: These calculations for determining the SO_2 and NO_x limits when a combination of lignite and PRB coal is burned do not seem consistent with the language in the SIP text, pp. 24 and 26, which states that the limits are the same whether burning PRB coal alone or in combination with lignite. Please clarify/resolve this inconsistency.

Response to Comment #51:

The language in the SIP has been corrected.

Comment #52:

II.A.1.g.: There appears to be a typo in the last sentence. The reference should be to II.A.4.b.(5), not III.A.4.b.5.

Response to Comment #52:

The change has been made to the permit.

Comment #53:

II.A.4.b.(5): The phrase "EPA-approved" was deleted from the last sentence regarding other test methods and should be corrected.

Response to Comment #53:

The requested change has been made.

Comment #54:

II.A.4.b.(7): A cross-reference to II.A.1.c. should be included. Based on conversations between our staffs, we understand that you have agreed to make this change.

Response to Comment #54:

The requested change has been made.

EPA Comments on
Draft BART Assessments
Milton R. Young Station
and Leland Olds Station

Comment No.: 1
Commentor: EPA (4)
Affected Source: General
Comment Summary: Suggest BART limit be written as % reduction and lb/10^6 Btu.
Response: The BART Guideline provides a choice. The Department's proposed limits are consistent with the BART Guideline. If the BART limit is only written as a lb/10^6 Btu limit, it will be higher than 0.15 lb/10^6 Btu.

Comment No.: 2
Commentor: EPA (5)
Affected Source: M.R. Young 2
Comment Summary: The 90% reduction requirement is not included in the Department's analysis.
Response: This is incorrect. There is a discussion of the 90% reduction requirement on p. 38.

Comment No.: 3
Commentor: EPA (10)
Affected Source: General
Comment Summary: EPA will be evaluating our response to Minnesota's "ask" memorandum.
Response: A response has been sent to Minnesota.

Comment No.: 4
Commentor: EPA (15)
Affected Source: General
Comment Summary:
(A) More information is needed to determine if K-Fuels is a viable option.
(B) EPA believes TurboSorp is technically feasible.
Response:
(A) K-Fuels has been under development for 20 years or more. The only commercial demonstration facility was near Gillette, Wyoming. According to Evergreen Energy's website the Wyoming plant has been idled in order to direct its capital and management resources to support a new design. At this time, we believe the K-Fuels process is not commercially available for North Dakota lignite.
(B) TurboSorp is a trademark for Babcock Power's circulating dry scrubber. The Minnkota, Basin Electric and GRE Stanton analyses all found circulating dry scrubbers to be technically feasible. The GRE Coal Creek analyses has been modified to address a circulating dry scrubber.

Comment No.: 5
Commentor: EPA (17), (18), (28)
Affected Source: General
Comment Summary: The citation of 40 CFR 60, Subpart Da in the proposed permit is problematic.
Response: The citation has been removed.

Comment No.: 6
Commentor: EPA (19), (29)
Affected Source: General
Comment Summary: The phrase "and the effective dates of the BART emission limits" should be removed.
Response: The phrase has been removed.

Comment No.: 7
Commentor: EPA (20)
Affected Source: Leland Olds Unit 1
Comment Summary: The emission factor of 35(s) is incorrect.
Response: The factor is not incorrect. Based on actual CEM data, a factor higher than AP-42 is warranted. In the Department's periodic review of PSD SO_2 increment consumption an emission factor of 37.4(s) was justified. For the BART analysis, an emission factor of 35(s) was used to provide a conservative estimate of the uncontrolled emission rate.

Comment No.: 8
Commentor: EPA (21) FLMs
Affected Source: Leland Olds 2
Comment Summary: A 5 factor analysis is required even though the most efficient control technology is used.
Response: The BART Guideline Step 1, Paragraph 9, states "... if a source commits to a BART determination that consists of the most stringent controls available, then there is no need to complete the remaining analyses in this section." Basin had proposed the highest available control efficiency and lowest possible emission rate. Therefore, the other steps of a BART analysis were not required. The Department has now determined that SCR w/reheat is technically feasible. A visibility analysis of SCR vs SNCR has been included.

Comment No.: 9
Commentor: EPA (22)
Affected Source: Leland Olds 1
Comment Summary: It is unclear how some of the 16 control options were eliminated.
Response: The explanation is found on p. 47-50 of the Basin Electric analysis.

Comment No.: 10
Commentor: EPA (23)
Affected Source: Leland Olds 2
Comment Summary: EPA believes SCR is technically feasible.

Response: The Department believes high dust SCR is not technically feasible due to catalyst poisoning by sodium and potassium. A detailed explanation of this issue is found in Appendix B.5. The Department now believes low dust and tail end SCR are technically feasible for North Dakota lignite-fired power plants.

Comment No.: 11
Commentor: EPA (24)
Affected Source: Leland Olds 2
Comment Summary: Typo on table heading on p. 39.
Response: Agreed - Correction made.

Comment No.: 12
Commentor: EPA (25)
Affected Source: Leland Olds
Comment Summary: PM limits listed on p. 44-25 are 0.05 lb/10^6 Btu.
Response: The table has been corrected to list the limit of 0.07 lb/10^6 Btu.

Comment No.: 13
Commentor: EPA (26)
Affected Source: Leland Olds
Comment Summary: Summary lists an NO_x emission limit of 0.18 lb/10^6 Btu.
Response: The limit has been revised to 0.19 lb/10^6 Btu and the emission reduction calculated accordingly.

Comment No.: 14
Commentor: EPA (27)
Affected Source: Leland Olds
Comment Summary: Appreciate the 98th percentile results.
Response: No response necessary.

Comment No.: 15
Commentor: EPA (30)
Affected Source: Leland Olds
Comment Summary: Add “Average ER = average actual emission rate” to permit.
Response: Agreed

Comment No.: 16
Commentor: EPA (31)
Affected Source: Leland Olds
Comment Summary: The phrase “or portable analyzer” was deleted and should be included in the permit.
Response: Agreed

Comment No.: 17
Commentor: EPA (36)
Affected Source: M.R. Young
Comment Summary: The August 2007 analysis relies too heavily on the CD.

Response: Minnkota prepared a BART analysis dated October 2006 and supplemented it with additional information dated August 2007. The two documents combined address all 5 factors for the three pollutants evaluated.

Comment No.: 18
Commentor: EPA (37)
Affected Source: M.R. Young 1
Comment Summary: The presentation of the 98th percentile visibility results in Appendix A is not an acceptable presentation.

Response: M.R. Young is not subject to the BART Guidelines. If it were, an evaluation of visibility impacts is not required since Minnkota has agreed to install the most stringent technology with the lowest possible emission rate.

Comment No.: 19
Commentor: EPA (38), (40), (42)
Affected Source: M.R. Young
Comment Summary:

A. Startup/shutdown exemption are not acceptable.
B. No visibility analysis was provided.
C. They believe the presumptive limits apply.
D. The NO_x BART analysis is deficient since the NO_x BART analysis process has not been completed.

Response:

A. Alternative limits for startup/shutdown is an accepted practice for BACT permits. EPA, in the Desert Rock PSD permit, included alternative NO_x limits for startup/shutdown. Minnkota has justified the alternative limits for startup. The BART Guidelines do not preclude these alternative limits. Therefore, the Department will maintain the limits for startup.
B. The visibility modeling results have been provided.
C. The nameplate capacity of the station is 734 MWe. The URGE is based on the capability of the unit for four hours. It does not represent long-term capability. Other rules such as the Acid Rain Program uses the nameplate capacity which is a verifiable value. We believe the Regional Haze Program should use it also. We disagree that the facility is subject to the presumptive emission limits. The DOE lists the M.R. Young Station as having a net summer capacity of 705 MWe for 2006.
D. An analysis of BART has been provided that is independent of the BACT assessment.

Comment No.: 20
Commentor: EPA (41)
Affected Source: M.R. Young
Comment Summary: PM limits are problematic.
Response: The PM limits will be listed separately in the Permit to Construct.

Comment No.: 21
Commentor: EPA (43)
Affected Source: M.R. Young
Comment Summary: The phrase “EPA approved” should be added back into the permit.
Response: Agreed

Comment No.: 24
Commentor: EPA (3)
Affected Source: MDU Heskett
Comment Summary:

A. A one km grid size may inappropriately reduce predicted concentrations. MDU used the annual average background visibility conditions while the North Dakota protocol requires use of the 20% cleanest days background.

B. MDU has volunteered SO_2 reductions at Heskett 2. How is this voluntary reduction formalized? Is NDDH taking credit for these reductions under reasonable progress and are the reductions included in the 99,000 tpy figure. How does NDDH intend to make the agreement federally enforceable?

Response:

A. The North Dakota modeling protocol only indicates that the “preferred” grid cell size is 3 km. The protocol does not prohibit a source from using a smaller size grid cell. We have no evidence to suggest that the smaller grid cells provides inaccurate results. MDU has provided justification for the one kilometer spacing (see Appendix A.2).

The North Dakota protocol was developed when EPA was interpreting the BART Guideline to require the use of 20% cleanest days background. EPA subsequently changed its position and allowed the use of the annual average background. Since EPA changed its interpretation, the Department had to allow the use of the annual average background since the State cannot, by law, be more stringent than Federal requirements.

B. The voluntary reductions were formalized by letter. The requirement for 70% reduction will be included in a Federally enforceable Permit to Construct.

The Department will take credit for the reduction under the reasonable progress goals and the reduction is included in our calculation of total SO_2 emissions reductions.

By issuing a Permit to Construct, which will be included in the regional haze SIP, the reductions will be made federally enforceable.

NDDH BART Determination:

32. Relative to the Future Case Table on page 10, we agree that the alternative labeled "Existing Scrubber & 27% Bypass" and that also has 83.1% control efficiency is in error. It has been corrected to read "Existing Scrubber & 0% Bypass."

You are correct that the Future Case Table does not contain an adjustment to Btu content to reflect dried coal. The BART Determination text will be revised to be clear on that point. The only adjustment made to the baseline uncontrolled SO_2 emissions was to reflect the projected increase in coal sulfur content based on mine core sampling. The 1.1% future coal sulfur content is an "as received for raw coal" value. If the SO_2 baseline is adjusted to reflect the switch from past raw coal at 6,200 Btu/lb to future dried coal at 7,200 Btu/lb, then the future coal sulfur content also must be adjusted (to approximately 1.4%) to reflect the drying so that the Btu/lb and the sulfur content remain on the same basis. The results of applying these adjustments are shown in Table 1 and Table 2 below for information only. These adjustments make the wet scrubber modification an even more favorable choice when compared to the wet scrubber replacement.

We do not intend to make these changes to the BART Determination because we cannot be reasonably sure of the future fuel moisture or Btu content. Although the GRE analysis indicates the intent to use dried lignite, the BART determination and the Permit to Construct neither require dried lignite nor limit the moisture content. Limiting the fuel characteristics is unnecessary because the BART determination recommends, and the Permit to Construct limits, the maximum SO_2 lb/10^6 Btu or minimum percent reduction.

Table 1: Future Case (Dried Lignite)

Alternative	**Control Efficiency (%)**	**Baseline Uncontrolled Emissions (tons/yr)***	**Controlled Emissions***	
			(tons/yr)	**(lb/10^6 Btu)****
Wet Scrubber Replacement***	95	66,209	3,310	0.126
Wet Scrubber Modification***	95	66,209	3,310	0.126
Spray Dryer***	90	66,209	6,621	0.251
Existing Scrubber***	83.1	66,209	11,189	0.424
Dry Sorbent Injection***	70	66,209	19,863	0.753
Existing Scrubber & 27% Bypass	68****	66,209	21,187*****	--

* Future dried lignite at 1.4% sulfur content. GRE-predicted 1.10% worst-case sulfur content for Falkirk Mine raw lignite. This was adjusted to 1.4% due to drying. As a

result, the Department's baseline future emission estimates are somewhat higher than GRE's estimates.

** Annual

*** 0% bypass

**** Current control rate

***** Current controlled emissions = 76,888(1-0.68) = 24,604 tpy (6200/7200 Btu/ton) = 21,187 tpy

Table 2: Costs of Compliance (Dried Lignite)

Alternative	**Emissions Reduction (tons/yr)**	**Annualized Cost ($)***	**Cost Effectiveness ($/ton)**	**Incremental Cost ($/ton)**
Wet Scrubber Replacement	17,877	30,760,000	1,721	29,020
Wet Scrubber Modification	17,877	11,520,000	644	--
Spray Dryer**	14,566	29,220,000	2,006	--
Existing Scrubber	9,998	9,840,000	984	N/A
Dry Sorbent Injection**	1,324	12,520,000	9,456	N/A

* Costs provided by GRE

** Inferior option to wet scrubber modifications

*** 0% bypass

N/A -- Not applicable since the cost of the less efficient alternative is more than the more efficient alternative

33. The Permit to Construct has been revised to require the modified wet scrubber to achieve the same level of SO_2 control efficiency as wet scrubber replacement: 95% (30-day rolling average) on the inlet SO_2 concentration to the scrubber or 0.15 lb/10^6 Btu (30-day rolling average). With this change, wet scrubber replacement would provide no improvement in visibility at any Class I area and would result in additional cost over wet scrubber modification ($24,987/ton incremental cost).

34. While we are not certain it is inappropriate to consider capital recovery of at least some of the ash sales infrastructure, we looked at the impact of disregarding all of that cost in the analysis of SNCR. It appears the annualized cost would change from $22,900,000 to $21,750,000; the cost effectiveness would change from $8,551/ton to $8,122/ton; and the incremental cost would change from $20,766/ton to $19,692/ton. These changes appear small when compared to the values for the NOx control option selected, SOFA/LNB Opt 1.

Regarding the request for additional information to evaluate the GRE position that employing SCR or SNCR technology may negatively affect fly ash sales due to ammonia slip, the attached GRE email dated 8/8/08 at 3:19 p.m. provides that additional information. The Department also considered a summary of a University of Kentucky study on the issue (attached) and has reached the following conclusions.

- SCR and SNCR use at Coal Creek Station will likely result in ammonia in the fly ash.
- The level of ammonia in the fly ash cannot be predicted with a reasonable certainty.
- The maximum level of ammonia in fly ash that would preclude negative impacts on the salability of the ash cannot be predicted.

Therefore, the Department cannot determine with reasonable certainty that SCR or SNCR will not result in a level of ammonia in the ash that could reduce or eliminate future ash sales. Any regulator who determines that SCR or SNCR will not jeopardize ash sales would be obligated to present the evidence in support of that position. While another regulator might determine that even a small improvement in visibility is worth GRE taking the risk of lost ash sales, making a wrong decision on this one will inflict a significant financial penalty on GRE and send ash to a landfill instead of it being used beneficially. Having considered all of the information available, the NDDH BART determination on this matter remains unchanged and the Department considers the issue resolved.

NDDH Proposed Permit to Construct for BART – Coal Creek:

35. The Coal Creek Permit to Construct wording at Condition II.A.1.c has been changed as suggested.

Albuquerque, NM 87104

Re: Regional Haze Contacts

Dear Mr. Cronin:

The North Dakota Department of Health is in the process of preparing a State Implementation Plan (SIP) to reduce the impact from regional haze in the Class I areas of the North Dakota. The Department has been involved with the Western Regional Air Partnership (WRAP) which serves as the coordinating body for the consultation process in the development of the SIP. The North Dakota Department of Health would like to provide you the opportunity to participate in our SIP development process.

Enclosed is a list of the contacts within the Department of Health who are involved in the North Dakota SIP development process. We encourage you to share this letter with any tribe that wishes to coordinate with the Department in the development of North Dakota's regional haze SIP.

If you have any questions regarding the SIP preparation or schedule, please feel free to contact Dana Mount at (701)328-5150.

Sincerely,

Terry O'Clair

Terry L. O'Clair, P.E.
